

21st Annual Congress of the
EUROPEAN COLLEGE OF SPORT SCIENCE
CROSSING BORDERS THROUGH SPORT SCIENCE

6th - 9th July 2016, Vienna - Austria

Hosted by the Centre for Sport Science and University Sports, University of Vienna

Book of Abstracts

Edited by: Bacq A., Wessner B., Diketmüller R., Tschan H., Hofmann M., Kornfeind P., Tsolakidis E.

21st Annual Congress of the

EUROPEAN COLLEGE OF SPORT SCIENCE

6th - 9th July 2016, Vienna – Austria

BOOK OF ABSTRACTS

Edited by:

Baca A., Wessner B., Diketmüller R., Tschan H., Hofmann M., Kornfeind P., Tsolakidis E.

Hosted by the University of Vienna

Organisation

Congress President

- Arnold Baca (AUT)

ECSS Executive Board

- Tim Cable - President (QAT)
- Marco Narici – Past President (GBR)
- Joan L. Duda - President Elect (GBR)
- Erich Müller (AUT)
- Bente Klarlund Pedersen (DEN)
- Stephen Seiler (NOR)

ECSS Scientific Board

- Flemming Dela - Chair (DEN)
- Jan Cabri - Secretary (NOR)
- Paul Greenhaff (GBR)
- Albert Gollhofer (GER)
- Martin Halle (GER)
- Susanna Hedenborg (SWE)
- Luc van Loon (NED)
- Abigail Mackey-Sennels (GBR)
- Nicole Wenderoth (SUI)

ECSS Scientific Committee

- José Antonio López Calbet (ESP)
- Annalisa Cogo (ITA)
- Wim Derave (BEL)
- Peter Federolf (NOR)
- Taija Finni (FIN)
- Markus Gruber (GER)
- Jørn Wulff Helge (DEN)
- Ylva Hellsten (DEN)
- Pierre-Nicolas Lemyre (NOR)
- Johannes van Lieshout (NED)
- Maria Francesca Piacentini (ITA)
- Afroditi Stathi (GBR)
- Cecilie Thøgersen-Ntoumani (AUS)
- Janice L. Thompson (GBR)

ECSS Office

- Thomas Delaveaux (GER)
- Elias Tsolakidis (GRE)
- Steffen Neubert (GER)
- Juliane Melber (GER)
- Tuulia Hokkanen (FIN)
- Alexandra Zavadská (SVK)

Chairs Organizing Committee

- Harald Tschan (AUT)
- Otmar Weiß (AUT)
- Martina Hochmeister-Postl (AUT)

Local Organizing Committee

- Maria Dinold (AUT)
- Michaela Haßmann (AUT)
- Marlene Hofmann (AUT)
- Philipp Kornfeind (AUT)
- Clemens Ley (AUT)
- Karl Schörghuber (AUT)
- Christoph Triska (AUT)

Chairs Local Scientific Committee

- Barbara Wessner (AUT)
- Rosa Diketmüller (AUT)
- Arnold Baca (AUT)

Local Scientific Committee

- Günter Amesberger (AUT)
- Norbert Bachl (AUT)
- Michael Kolb (AUT)
- Erich Müller (AUT)
- Hermann Schwameder (AUT)
- Gerhard Smekal (AUT)
- Markus Tilp (AUT)
- Sylvia Titze (AUT)
- Harald Tschan (AUT)
- Otmar Weiβ (AUT)

Reviewers

- Günter Amesberger (AUT)
- Arnold Baca (AUT)
- Norbert Bachl (AUT)
- Pascal Bauer (AUT)
- Tim Cable (QAT)
- Daniela Caporossi (ITA)
- Rosa Diketmüller (AUT)
- Minas Dimitriou (AUT)
- Maria Dinold (AUT)
- Bernhard Franzke (AUT)
- Timothy Hasenöhrl (AUT)
- Richard Hauer (AUT)
- Mario Heller (AUT)
- Marlene Hofmann (AUT)
- Konrad Kleiner (AUT)
- Michael Kolb (AUT)
- Martin Kopp (AUT)
- Philipp Kornfeind (AUT)
- Roland Leser (AUT)
- Clemens Ley (AUT)
- Daniel Memmert (GER)
- Erich Müller (AUT)
- Rudolf Müllner (AUT)
- Alfred Nimmerichter (AUT)
- Rochus Pokan (AUT)
- Petra Polster (AUT)
- Susanne Ring-Dimitriou (AUT)
- Martin Schnitzer (AUT)
- Hermann Schwameder (AUT)
- Gerhard Smekal (AUT)

- Michael Stöckl (AUT)
- Eva-Maria Strasser (AUT)
- Markus Tilp (AUT)
- Sylvia Titze (AUT)
- Christoph Triska (AUT)
- Harald Tschan (AUT)
- Karl-Heinz Wagner (AUT)
- Otmar Weiß (AUT)
- Inge Werner (AUT)
- Barbara Wessner (AUT)
- Klaus Wirth (AUT)
- Kerstin Witte (GER)

Head of Volunteers

- Marlene Hofmann (AUT)
- Philipp Kornfeind (AUT)

Welcome

On behalf of the European College of Sport Science and the Centre for Sport Science and University Sports of the University of Vienna we welcome you to Vienna for the 21st Annual Congress of the ECSS.

The University of Vienna was founded in 1365, is the largest university in Austria and is one of the oldest universities in the German speaking world. The Centre for Sport Science and University Sports is one of the 19 faculties/centres of this university. It includes the Institute of Sport Science representing the scientific sub division and the University Sports Institute, being the central institution for college sports in Vienna.

"Crossing Borders through Sport Science" as the conference theme reflects the long-lasting tradition of Austria in bringing together people from all over the world but also the emphasis of the European College to fully cover all disciplines and topics within Sport Science. The Vienna conference provides a platform for an exchange of views and research ideas, the discussion and presentation of current research results as well as the realisation of joint research projects.

We are proud that due to excellent submissions we have been able to put together an outstanding scientific program that highlights the current state of knowledge in sport science. The program comprises four plenary sessions and 36 invited symposia on topical issues in the field. In total more than 2000 abstracts have been submitted from 66 countries. 1802 abstracts were selected for the final programme and allocated to 100 oral, 70 mini-oral and 36 conventional poster sessions or assigned to E-poster presentation. 95 oral and 21 mini-oral presentations were selected for the Young Investigator Award (YIA).

Visiting a conference not only is to meet other scientists but also to grab the spirit of the hosting city and its surroundings. Vienna has transformed from a Roman settlement to the capital of the Austrian-Hungarian Empire, finally becoming the capital of the modern Austrian state with about 2 million inhabitants. Since several years Vienna is ranked number one concerning the quality of living which reflects not only political and economical factors but also health, education and public service including transportation. Vienna combines historical heritage with modernity not only when visiting museums, concerts and the numerous theatres but also when relaxing at one of the numerous restaurants, bars and of course at the classical "Heurigen" in the vineyards of Vienna.

Enjoy Vienna,

Arnold Baca (University of Vienna)

Congress President

Table of Contents

ORGANISATION.....	3
WELCOME.....	6
TOM REILLY MEMORIAL LECTURE.....	15
WEDNESDAY, JULY 6TH, 2016.....	18
12:00 - 13:00.....	18
PO-CPP-01 BIOMECHANICS 1.....	18
PO-CPP-05 ADAPTED PHYSICAL ACTIVITY.....	20
PO-CPP-09 HEALTH & FITNESS 1.....	23
PO-CPP-13 NEUROMUSCULAR PHYSIOLOGY 1.....	26
PO-CPP-17 PHYSIOLOGY 1.....	28
PO-CPP-21 SPORT DEVELOPMENT & SOCIOLOGY.....	31
PO-CPP-25 SPORTS MEDICINE & ORTHOPAEDICS 1.....	33
PO-CPP-29 TRAINING & TESTING 1.....	36
PO-CPP-33 PHYSICAL EDUCATION & PEDAGOGICS 1	38
13:00 - 14:00	40
MO-PM06 NUTRITION & SUPPLEMENTATION	40
OP-PM01 GSSI PRESENTATIONS: NUTRITION	43
MO-PM04 BODY COMPOSITION 1.....	45
MO-PM08 ENVIRONMENT	48
MO-BN03 MUSCLE - TENDON	52
MO-PM01 HEALTH PROMOTION	55
MO-PM47 MIXED SESSION: INJURY & ADAPTED PHYSICAL ACTIVITY.....	59
MO-SH11 PSYCHOLOGY: AGEING & RISK GROUPS.....	62
MO-SH10 PSYCHOLOGY: COGNITION, PERFORMANCE, CAREER TRANSITIONS.....	65
MO-SH03 SPORT STATISTICS & ANALYSIS: TEAM SPORTS.....	68
14:00 - 15:00	72
MO-PM46 NUTRITION & SUPPLEMENTS.....	72
MO-PM05 BODY COMPOSITION 2.....	75
MO-PM11 ESSA-ECSS EXCHANGE (CARDIOVASCULAR)	77
MO-PM10 FATIGUE	80
MO-PM03 AGEING 1.....	83
MO-PM33 STRENGTH TRAINING & TESTING.....	86
MO-PM52 SPORTS MEDICINE: SPORTS INJURIES.....	90
MO-SH12 PSYCHOLOGY: TEAM SPORTS.....	93
MO-SH02 SPORT STATISTICS & ANALYSIS	96
MO-SH06 SPORT MANAGEMENT.....	98
15:00 - 16:30	101
IS-PM01 TAKING CARE OF THE RESPIRATORY HEALTH OF ELITE ATHLETES.....	101

OP-PM02 ASPETAR PRESENTATIONS: FOOTBALL.....	102
IS-PM02 NUTRITIONAL SUPPLEMENTS TO IMPROVE HEALTH AND PERFORMANCE.....	104
IS-PM03 OXYGEN UPTAKE KINETICS IN PERFORMANCE, HEALTH AND DISEASE.....	105
IS-BN01 TECHNOLOGY AND MODELLING IN GAME SPORTS.....	106
IS-BN02 BIOMECHANICAL FUNDAMENTALS, ADAPTATIONS AND IMPAIRMENTS OF LOWER LIMB FUNCTION.....	107
IS-SH01 THE FAN CAN: THE MEDIA AND FOOTBALL SUPPORTER COMMUNITIES AS ENABLERS OF MULTICULTURAL ENVIRONMENTS.....	108
IS-SH02 INTERCULTURALITY IN SPORTS – DIFFERENT APPROACHES, EFFECTS AND DILEMMAS.....	109
IS-EX01 ECSS - ACSM EXCHANGE SYMPOSIUM: PREPARING FOR THE OLYMPICS - AN EUROPEAN AND AMERICAN VIEWPOINT.....	110
OP-PM13 MUSCLE STRENGTH.....	111
OP-PM12 SPORTS MEDICINE: INJURY - TENDONS.....	113
OP-SH10 PSYCHOLOGY: MOTIVATION 1.....	114
OP-PM05 BRAIN & COGNITIVE FUNCTION	116
OP-BN04 EXERCISE IN ELDERLY: BALANCE & RUNNING	119
OP-SH03 FANSHIP, MEDIA & MEGAEVENTS.....	121
16:45 - 18:00.....	122
PS-PL01 CROSSING THE LIMITS OF IMPAIRMENT – LESSONS FROM NEUROMUSCULAR AND CARDIOVASCULAR FUNCTION AFTER SPINAL CORD INJURY	122
THURSDAY, JULY 7TH, 2016.....	123
08:00 - 09:30.....	123
OP-PM06 NITRATE & DIET COMPOSITION.....	123
OP-PM07 HEALTH & FITNESS	125
OP-BN01 BIOMECHANICS	127
OP-PM08 LIVER & MITOCHONDRIA	129
OP-PM47 PHYSIOLOGICAL RESPONSE TO HIT.....	131
OP-PM55 LOW BACK PAIN	133
OP-PM36 HANDBALL PERFORMANCE	135
OP-PM18 TRAINING & TESTING: MIXED SESSION	137
OP-PM24 INDICATORS OF FATIGUE	138
OP-PM10 MUSCLE GROWTH.....	141
OP-BN11 PERFORMANCE TESTS.....	142
OP-PM16 MIXED SESSION: TRAINING & EXERCISE.....	144
OP-BN03 MOTOR LEARNING & CONTROL.....	146
OP-PM79 REGENERATION: MIXED SESSION.....	148
OP-SH01 SPORTS HISTORY.....	150
09:45 - 11:15	151
IS-PM04 ACTIVE PREGNANCY	151
IS-SP02 SPORTS NUTRITION SYMPOSIUM - PRIME, PERFORM AND RECOVER: EXPLORING NUTRITION STRATEGIES SURROUNDING EXERCISE SPONSORED BY GSII.....	152
IS-PM05 IMPACT OF EXERCISE ON VASCULAR DISEASE: BENEFITS AND MECHANISMS.....	153
OP-PM09 SUPPLEMENTS: PROTEIN, CREATINE, CAFFEINE	154
IS-BN03 HAMSTRING MUSCLE FUNCTION IN HUMAN MOVEMENT: IMPLICATIONS FOR HAMSTRING STRAIN INJURY DETECTION AND PREVENTION.....	156
IS-BN04 FATIGUE AND FATIGABILITY IN HEALTH AND DISEASE.....	157
IS-SH03 EVIDENCE-BASED PHYSICAL ACTIVITY POLICY	158

IS-SH04 SPORT WITH PEOPLE CROSSING BORDERS.....	159
IS-EX02 CSSS - ECSS EXCHANGE SYMPOSIUM: PHYSICAL ACTIVITY AND HEALTH PROMOTION (CHINA).....	160
OP-PM11 MOLECULAR BIOLOGY & BIOCHEMISTRY	160
OP-PM15 PERFORMANCE & WATER	162
OP-SH02 PSYCHOLOGY: SPORT PERFORMANCE.....	164
OP-SH25 CHILDREN & PHYSICAL EXERCISE	167
OP-SH20 SPORT CONSUMERS, EVENTS & TOURISM.....	168
11:30 - 12:45	169
PS-PL02 PROMOTING PHYSICAL ACTIVITY – ENVIRONMENTAL AND ECONOMIC HEALTH APPROACHES	169
13:00 - 14:00	170
PO-CPP-02 BIOMECHANICS 2	170
PO-CPP-06 HEALTH & FITNESS 2	172
PO-CPP-10 HEALTH & FITNESS 3	176
PO-CPP-14 NUTRITION 1	179
PO-CPP-18 PHYSIOLOGY 2	182
PO-CPP-22 REHABILITATION & PHYSIOTHERAPY 1.....	186
PO-CPP-26 TRAINING & TESTING 2.....	189
PO-CPP-30 TRAINING & TESTING 3	193
PO-CPP-34 PSYCHOLOGY 1.....	195
14:00 - 15:00	197
MO-PM22 DIET & GLUCOSE.....	197
MO-PM31 NUTRITION & PERFORMANCE	200
MO-PM27 AGEING 2	203
MO-PM23 FITNESS PERCEPTION & PERFORMANCE	206
MO-BN01 RUNNING BIOMECHANICS	209
MO-SH01 COACHING & TALENT MONITORING.....	212
MO-PM07 TEAM SPORTS	215
MO-PM53 COACHING: TRAINING EFFECTS	218
MO-PM43 TRAINING & TESTING 1	221
MO-PM48 REHABILITATION: PHYSIOTHERAPY	223
MO-PM50 TRAINING & TESTING: JUMPING	227
MO-SH08 PSYCHOLOGY: MIXED SESSION	230
MO-SH04 SOCIOLOGY & PHILOSOPHY.....	234
15:00 - 16:00.....	236
MO-PM35 HORMONES.....	236
MO-PM45 NUTRITIONAL STRATEGIES.....	239
MO-PM14 AGEING 3.....	243
MO-PM26 FITNESS & ENERGY EXPENDITURE.....	245
MO-BN13 NEURAL RESPONSES	248
MO-PM09 HEALTH & EXERCISE	252
MO-BN02 CYCLING	255
MO-PM40 TRAINING & TESTING: SWIMMING/TENNIS	258
MO-PM49 TRAINING & TESTING 2	262

MO-PM36 RECOVERY METHODS.....	265
MO-SH07 PHYSICAL EDUCATION AND PEDAGOGICS	267
MO-BN12 MOTOR LEARNING.....	270
16:15 - 17:45.....	273
IS-PM06 HIT TRAINING - MECHANISMS AND APPLICABILITY	273
IS-PM07 MITOCHONDRIAL FUNCTION AND ADAPTATION TO STRESSORS	274
IS-SP01 HEAT AND ALTITUDE TRAINING FOR ELITE ATHLETES SPONSORED BY ASPETAR	275
OP-PM03 OXYGEN UPTAKE & METABOLISM.....	276
IS-BN05 INTEGRATIVE FALL PREVENTION – NOVEL STRATEGIES TO TEST AND TRAIN NEUROMUSCULAR AND CARDIAC FALL RISK FACTORS IN THE ELDERLY.....	278

EDUCATION - NOT THE FILLING OF A PAIL, BUT THE LIGHTING OF A FIRE

ATKINSON, G.

Teesside University

The above quote is from the great Irish poet, W.B. Yeats, who won the Nobel Prize for literature in 1923. Yeats contributions to poetry were highlighted in 1941 by another great Irish writer, Louis MacNeice. In that same year, yet another great Irish man was born who ultimately came to represent perfectly the words of wisdom in Yeats' quote. That man was Professor Tom Reilly.

Tom never "spoon-fed" his students, but allowed them a tremendous amount of freedom to think for themselves. Tom's unwavering confidence in his student's abilities often led them into challenging, yet very rewarding, activities. Tom had no hesitation in sending his students - sometimes while they were still in their PhD programmes - to international congresses, and sometimes to deliver one of his own overview lectures if the demands for Tom's presentations were especially high, as they often were. And today I find myself honoured to be able to deliver another lecture – this one at the esteemed ECSS Congress – and yet again, all thanks to my great mentor, Tom Reilly.

One of the many sparks that Tom ignited in me was an appreciation of all the different types of research approaches - and how one should never rely on just one of these to ultimately inform practice in exercise science. During my PhD and afterwards, Tom directed me through many laboratory-based experiments into the human body clock. Such was the man's influence on me - I would think nothing of going two days without sleep to get these experiments completed on time. After all, I was working for the great Tom Reilly; a stunning academic and an accomplished athlete, who, in one experiment, completed 100 hours of non-stop exercise - just to further science.

Tom was a great believer in real-world applied research methods and I know I can speak for many of his other students by saying how much he tutored us in undertaking randomised controlled trials of jet lag treatments following actual flights. We completed many such RCTs on Olympic athletes and their support staff, often trying to keep up with Tom's preference for 16-hour working days on these trips, as well as putting up with some really inventive insults from the athletes when we woke them at 5:30am for their first tests of the day!

Tom instilled in me a real sense of wonder about circadian rhythms and jet lag, as well as the importance of not being entrenched in one "camp" or another regarding a certain theory or hypothesis. Often our real world RCTs on jet lag treatments did not result in practically-important or statistically significant effects in the elite athletes - even though evidence from our own laboratory-based studies indicated that these treatments had potential. Tom had no problem with such disagreement between the tightly-controlled laboratory and the more labile "fire" of the real world, knowing that this is essentially evidence translation in action.

Tom - Thank you for lighting up the fire of education in me. I am certainly not the only one in this room who owe you this gratitude.

KINEMATICS OF SPRINT START FOR MASTERS' ATHLETES

KIJIMA, K., URATA, T., OHTA, Y., FUKUDA, K., NAKAI, A., ISHIKAWA, M., MERO, A., KOMI, P.V., ITO, A.

1.Osaka University of Health and Sport Sciences, 2.Kansai University, 3.Aichi Shukutoku University, 4.University of Hyogo, 5.Shizuoka University of Welfare, 6.University of Jyväskylä

The world records of masters' athletes are getting faster and faster. However, the training of masters' athletes has not been specifically considered as compared to the young athletes. Therefore, the purpose of the present study was to examine the characteristics of the support-leg movements for masters' sprinters and the changes of sprint start with aging in order to provide the training concepts for masters' sprinters. Sprint start movements for 17 male masters' sprinters (records: 11.02-19.83 sec) were recorded by two high-speed cameras (210fps) at the 100-m event of the World Masters Athletics Championships (2009, Finland). These subjects were finalists in each 5-yr age category race from 40 to 90 years old. Each step of their start movements were analyzed from the start to 4th steps with the direct linear transformation method and then the following parameters were calculated as the average of the 4 steps during the start phase: running velocity, step length, step frequency, as well as the joint and segment angles and these angular velocities of the support leg. In addition, these parameters of the world top level young sprinters (n=10, records: 9.85-11.16 sec) were added for considering the age-related specificity. At the start phase, the running velocities of masters' sprinters were from 3.50 m/s in 90 yr- to 4.65 m/s in 40-44 yr-old. Their running velocities were decreased with increasing age groups. When considered by the whole athletes, their step frequency did not show any relationship with their running velocities, but their step length was negatively related to their running velocities. In their support leg, the changes of the hip, knee and ankle joint angles and these angular extension velocities were negatively related to their running velocities. Both their upper and lower legs were rotated forward throughout the stance phase. The forward rotation velocity of the upper leg was negatively related to their running velocities. However, that of the lower leg did not show any relationship with their running velocities. These results suggest that the reduction of the running speed of masters' athletes can be related to their lower step length. These low step length of the masters' sprinters can be related by the reduction of the forward rotation velocity of the upper leg and the reduction of the extension velocity of the knee joint due to the decrease in hip extension and its velocity. Therefore, it is important to prevent the decrease of the hip extension and its velocity for training of masters' sprinters.

3D KINEMATIC COMPARISON OF MOTORIZED AND NON-MOTORIZED TREADMILL AND OVERGROUND RUNNING

GAHLEN, M., KRAKOWSKI-ROOSEN, H.

University of Applied Sciences Hamm-Lippstadt

The treadmill allows a larger number of steps to be captured and ensures that continuous movement kinematics are obtained. [1][2] The captured data from the treadmill gives a more repeatable pattern of movement in comparison compared to the short discontinuous trial associated with overground analyses. For this analysis a motorized treadmill (h/p/cosmos sports & medical gmbh Nussdorf-Traunstein, Germany) and a non-motorized curved treadmill (Woodway GmbH Weil am Rhein, Germany) were used as well as a 10m walktrack in the laboratory. Ten voluntary participants free from musculoskeletal injury ran with 3.5 m/s +5% on the treadmills and on the walktrack. The kinematic data were captured with an eight camera motion analysis system (Simi Reality Motion Systems GmbH, Unterschleißheim, Germany). Each mode of running were collected with the same camera setup. Based on the PlugInGait-Model the retroreflective marker were positioned on the lower extremities of the participants. The captured data was compared using a paired samples t-test in SPSS. The results indicate that several kinematic differences were observed between the three running modalities. There is an increased range of motion in hip flexion-extension on overground running and a reduced stride length on the treadmills. Further data is needed for enhancement of accuracy and reliability. COORDINATION OF MOVEMENT ON A KAYAK ERGOMETER

JAHN, C.1,2, WARNKE, T.1, UEBERSCHÄR, O.1, FICHTNER, I.1, WITT, M.2

1: IAT (Leipzig, Germany), 2: IABTW (University Leipzig, Germany)

Introduction The introduction of a sprint event (200 m) in flatwater kayaking into the Olympic program in 2009 encouraged higher boat speeds and therefore necessarily higher propulsive forces and power. This development emphasizes the optimization of the force transfer from athlete to water including the kinetic chain of legs, trunk and arms under the condition of an increased frequency. Begon, Colloud & Lacouture (2009) were the first to measure forces in the horizontal direction of a seat and footrest at an aerobic training pace. To our knowledge no systematic analysis of kinetic parameters under speed (i. e. stroke rate) regulation has been completed. Methods 7 German top athletes preparing for the World Championships in 2015 in Milano were tested on a kayak ergometer at 4 different stroke rates (60, 100, 140 und 160 strokes/min [spm]), corresponding to cycle durations between 2.00 s and 0.75 s. In trials of 15 s we measured forces on the paddle (1D, 100 Hz), seat (3D, 1000 Hz) and footrest (1D, left, right, 1000 Hz). All force curves were time normalized to 100 % and an average paddling cycle was calculated of six consecutive cycles, each beginning at the threshold of 30 N after paddle entry. A Wilcoxon signed-rank test was used to determine group differences. Results For the group a reduction of cycle duration led to a signifi-

cantly delayed development of peak force on the paddle from 8.4 % (median, at 60 spm) to 13.4 % (at 160 spm), $p = 0.001$, $r = -0.88$, and contralateral on the footrest from 9.3 % to 13.1 % ($p = 0.002$, $r = -0.83$) respectively. They reached peak forces during the right stroke at the same time on paddle and footrest, except at 160 spm the paddle peak force was developed 2.8 % (n. s.) later than the footrest peak. In left strokes the paddle peak force was developed before the footrest peak force for all paces (n. s.), reducing the gap with increasing stroke rates. Also in left strokes paddle peak forces were reached significantly earlier than in right strokes for all paces. Discussion The relatively small time shift of 5 % and 3.8 % at an enormous reduction of cycle time to one third is achieved through the sharp incline in force development on footrest and paddle. However the athletes show asymmetries in timing the peak forces on paddle and footrest, hinting at limitations in force transfer of the trunk. References Begon, M., Colloud, F., & Lacouture, P. (2009). Measurement of contact forces on a kayak ergometer with a sliding footbar-seat complex. Sports Engineering, 11, 67–73. QUANTITATIVE ANALYSIS FOR ACQUISITION OF SNATCH SKILL IN JUNIOR WEIGHT LIFTER

KASHIWAGI, K.1, YAMAGISHI, M.2, KASHIWAGI, N.3, KATO, T.4, FUNATO, K.2

1:Graduate school of Health and Sport Science, Nippon Sport Science University 2:Nippon Sport Science University 3:Japan Institute of Sports Sciences, 4:Japan Weightlifting Association, Tokyo Japan

Introduction A snatch competition of weightlifting requires explosive power output as well as high skill [1]. In particular explosive power output in 2nd pull phase was important in high level performance in national athlete. Preliminary research indicated it was a characteristic of a top-level athlete snatch skill kinematics data, but there are few reports [2] that they mentioned about snatch skill acquisition and important for a training program in junior weight lifter. The purpose of this study was to perform quantitative analysis of on the changing in snatch skill during eleven months between absolute and relative of weightlifting performance. Methods Six junior high school weight lifters (Male:4, Female:2, Age : 16.7 ± 0.6 yrs, BH: 164.7 ± 7.8 cm, BW: 69.7 ± 20.0 kg,) participated in this study. Subjects performed 80%IRM (Pre) snatch and measurement five times of eleven months total. In final measurement, subjects performed 80%IRM snatch of first time equal condition (Post). Kinematics data were recorded by using two digital video camera (60fps) synchronized by an electrical signal. A digitizing system (FrameDIAS-V, DKH) were used to digitize 5 anatomical landmark points on the body and the barbell. Lower joint (Hip, Knee, Ankle) angle, angular velocity, angular acceleration were calculated each five sub-phases (1st pull, Transition, 2nd pull, Turnover, Catch). All statistical analysis were used by paired t-test performed on selected means to detect significant differences (effective $p < 0.05$) between Pre and Best, Pre and Post respectability (JMP ver. 8.0 : SAS Inc.). Results and Discussion Subject' body composition (BW, %Fat and LBM) were not change during eleven months. On the other hand, Snatch best performance (Pre: 75.8 ± 13.6 kg vs. Best: 84.8 ± 17.8 kg, $p < 0.01$) and 80%IRM (Pre: 61.8 ± 12.1 kg vs. Best: 69.8 ± 14.7 kg, $p < 0.05$) were significantly increased during eleven months. Best (71.9 ± 13.4 rad/s 2 , $p < 0.05$) and Post (76.9 ± 17.0 rad/s 2 , $p < 0.05$) peak hip extension angular acceleration during transition phase were significantly increases compared with Pre (51.5 ± 9.9 rad/s 2). In Turnover phase, Best (-90.3 ± 14.3 rad/s 2 , $p < 0.05$) and Post (-105.2 ± 16.7 rad/s 2 , $p < 0.05$) peak hip flexion angular acceleration were significantly increases compared with Pre (-75.9 ± 12.6 rad/s 2). Conclusion Improvement of the snatch skill of junior weight lifter during eleven months was indicated the peak hip extension and flexion angular acceleration during transition and turnover phases, respectively. KNEE HYPEREXTENSION CAUSED BY THE UP-BEAT DOLPHIN-KICK MOVEMENT.

SANO, K., MAKINO, A., KUNIMASA, Y., HIROISHI, T., OZAKI, R., MIYASHITA, A., SAKAMOTO, T., ISHIKAWA, M.

Osaka University of Health and Sport Sciences

Introduction It was expected that the hyperextension of the knee joint in competitive swimmers can be affected by the repetitive action of the downbeat kick movements (Kenal & Knapp,1996). It is also believed that the hyperextension of the knee joint may increase the amplitudes of the down-beat dolphin kick and influence the swimming performance. However, it remains questionable whether the hyperextension of the knee joint can be advantageous for the dolphin kick performance of the competitive swimmers and whether the hyperextension of the knee joint in competitive swimmers would be caused by the congenital and/or acquired factors. Therefore, the purpose of this study was to examine relationships between the dolphin-kick performances, maximal knee extended joint angle on land and the maximal knee extended joint angle during underwater dolphin-kick swimming Methods 8 competitive college male swimmers (Age: 21 ± 1 yr, Height: 1.74 ± 0.07 m, Body mass: 67.1 ± 8.1 kg) were participated in this study. The maximal knee extended joint angles with the standing position and during the 25-m underwater dolphin-kick swimming were measured by the waterproof goniometer. The cross-sectional areas (CSA) of hamstrings muscles with the three parts (distal middle and proximal parts) were measured by ultrasonography. The time of the 25-m underwater dolphin-kick swimming with maximal efforts was used as their swimming performance. Results The swimming performance time was negatively related to the maximal knee extended joint angle during the dolphin-kick swimming ($r=-0.97$, $p < 0.001$) and to the CSA of hamstrings muscles in the proximal part ($r=-0.78$, $p < 0.05$). However, there were not any significant relationships between the maximal knee extended joint angle at the standing position and the maximal knee extended joint angle during the dolphin-kick swimming ($r=0.23$, $p=0.59$) and between the maximal knee extended joint angle at the standing position and the swimming performance time. There was a significant positive correlation between maximal knee extended joint angle during the dolphin-kick swimming and the hamstrings muscle CSA in the proximal part ($r=0.78$, $p < 0.05$). Discussion Our results clearly showed that the CSA of hamstrings muscles in the proximal part can play important roles to dolphin-kick swimming performance as well as the maximal knee extended joint angle during the dolphin-kick swimming. These results suggested that the maximal knee extended joint angle during the dolphin-kick swimming can be caused by the hip extended upbeat movement during the knee extended downbeat kick phase. This greater maximal knee joint extension movement can result in better dolphin-kick performance. References Kenal KA and Knapp LD,1996. Sports Med 22:337-347. Contact kanae.04.dec@gmail.com

KINEMATICS OF JUMP SHOT IN TOP SERBIAN BASKETBALL PLAYERS

BUBANJ, S., RADENKOVIĆ, M., STOJANOVIC, E., STANKOVIĆ, R.

University of Niš, Faculty of Sport and Physical Education

Do not insert authors here The aim was to determine the kinematics of jump shot by using the 94 Fifty Smart Sensor Basketball® methodology in the sample of top Serbian basketball players (N=18). Following kinematics parameters of jump shot from the distance of 6.096 m were measured: Release Angle (in degrees), Ball Rotation (in revolutions per minute) and Shot Release (in seconds). For the purpose of

statistical analysis of the data obtained, SPSS version 11 had been used, and the results are presented by descriptive statistics. The correlation and difference in arithmetic mean depending on the players' height and position were tested by Correlation Analysis (Pearson correlation coefficient) and Analysis of Variance (One-way ANOVA method), respectively. Players performed jump shots at more or less similar manner, regardless of the body height and team position, therefore no significant correlation and difference were determined. Further investigations are needed.

CORRELATION BETWEEN MOVEMENT VARIABILITY DURING STATIC STANDING AND ONE-LEGGED STANDING ABILITY IN FRAIL OLDER ADULTS

YAMAGATA, M., IKEZOE, T., KAMIYA, M., MASAKI, M., ICHIHASHI, N.

Kyoto University

Introduction Postural sway such as a trace length of center of pressure (CoP) is used commonly as a quantitative measurement of standing postural control. Recent researches, however, have shown that it is crucial to measure movement variability, which is qualitative alteration in time series (Lockhart T et al., 2013). Sample entropy (SE), a regularity statistic from nonlinear dynamics, is used as a practical method to quantify CoP dynamics. Small SE values indicate great regularity on postural control such as those seen in robots' movement, which is associated with lower degrees of freedom. One-legged standing time is also used commonly to represent postural stability, which is an easy and effective method without expensive instruments in clinical setting. However, no studies have investigated the correlation between movement variability and one-legged standing time in older adults. The aim of the present study was to investigate the associations of movement variability and postural sway during static standing with one-legged standing time in older adults. Methods The subjects comprised 36 older adults (age 82.2 ± 6.5 years). CoP during static standing on both legs was measured using a center of foot pressure recorder (Win-Pod, Finggal Link Co., Tokyo, Japan) in eyes open conditions. Standard deviation of CoP in frontal and sagittal planes (X-SD and Y-SD, respectively) was used as a quantitative parameter of postural sway SE in frontal and sagittal planes (SE-X and SE-Y, respectively) was used as a qualitative parameter. One-legged standing (OLS) time on the dominant foot with eyes open was measured for a maximum of 60 seconds. The trial was performed twice and the longer duration was used for analysis. Pearson's correlation coefficient was used to investigate the relationships between CoP measurements and OLS time. Results OLS time was 6.48 ± 6.3 sec. Correlation analysis revealed that OLS time was significantly and negatively correlated with SE-Y ($r=-0.407$), but not with SE-X. Furthermore, no correlation was found between OLS and X-SD or Y-SD. Discussion In the present study, there was a significant negative correlation between OLS time and SE-Y, which indicate that older adults who has lower SE-Y can maintain OLS for a longer time. Lower SE values indicate lower degrees of freedom. Our results suggest that older adults with lower standing ability may utilize the strategy that decreases the degree of freedom (increased joint stiffness) in sagittal plane to enable longer one-legged standing. KINETIC ANALYSIS OF TWO DIFFERENT SPRINT START POSITIONS IN SKILLED SPRINTERS

MILANESE, C., CAVEDON, C., PIRLO, M., ZANCANARO, C.

School of Exercise and Sport Sciences

Introduction In track sprints, the start is a crucial skill and its efficiency is an important determinant of the final performance. The athlete has to generate forces in the shortest time period to leave the starting blocks and reach the highest running speed as soon as possible (Fortier et al., 2005). Thus, the search of the optimal posture to perform this task is of great relevance to both coaches and athletes. The aim of this study was to assess the effects of two different block settings on kinetic and kinematic parameters in sprint start. Methods 27 skilled sprinters involved in regional to international level competitions performed a total of 6 maximal-effort 10-m sprints using two different starting conditions: 1) the athlete's usual personal block setting condition (UC) and, 2) a test condition (TC) in which the start block positions are set according to a calculation on the individual's leg length from the greater trochanter to lateral malleolus, 60% of this length being used for the front block/startling line distance and 45% for the inter-block distance (Schot & Knutzen, 1992). A set of dynamometric sprint blocks (Milanese et al., 2014) was used to measure the magnitude of forces generated by athletes. The time at 5m and 10m was recorded using an infrared photocell. Comparison of kinetics and kinematics variables in the two conditions was performed with paired samples t-test. Alpha was set at .05. Results Mean length distances in starting blocks were significantly different in the two setting conditions: starting line/front block distance, 52.9 ± 4.6 cm and 49.8 ± 2.4 cm ($p=.001$); inter-block distance: 27.4 ± 2.42 cm and 37.3 ± 1.9 cm ($p<.001$) in UC and TC, respectively. A significant increase was found in TC for total impulse ($p<.001$) and total block time ($p=.002$) as well as a decrease in the time at 5m ($p=.005$). The horizontal velocity was significantly greater in TC ($p=.003$) and the rear leg showed greater increase in the maximum resultant force and impulse ($p<.001$, $p=.018$, respectively). Discussion Our results indicate that a block setting based on the individual's leg length (TC) improves sprint start performance by enabling larger rear block forces and impulse; this, in turn, affects the efficiency of the push-off from the blocks. These results may be a consequence to the greater inter-block distance in the TC compared to the UC. Therefore, in sprinters, technical aspects like block positioning, should be considered alongside the usual strength training to maximise performance. Conventional Print Poster**PO-CPP-05 Adapted Physical Activity****BIOMECHANICAL EFFECT OF ROBOTIC EXERCISE FOR BOCCIA PLAYERS WITH CEREBRAL PALSY**

HATANAKA, Y.1, OKUDA, K.2, KATAOKA, N.2, TADA, S.1, YAMAGUCHI, K.1, SAITO, K.1

1:Suzuka University of Medical Science, 2:Osaka Prefectural University

Introduction Boccia is one of the common sports for where chair users. Throwing performance depends on the function of trunk control, which is affected by pelvic control muscles. However, where chair users do not have chances to activate these muscles during the activi-

ties daily lives. We hypothesized that the experiences to activate the Gluteus Maximus, Iliopsoas and Rectus Femoris muscle have positive impacts for throwing performance of boccia players. To control the loads of these exercises for weak muscles, supply of appropriate joint torque is necessary. Therefore, we employed an exoskeletal power assist robot to solve this problem. The purpose of this study is to clarify the effect of robotic exercise for boccia players. Methods Three volunteers of boccia players with cerebral palsy participated in the experiment. The university ethic committee approved the experimental protocol (2014-177). All subjects signed the consent form before experiment. HAL (Hybrid Assistive Limb: Cyberdyne Co. Japan) was employed for the exercise. HAL is an exoskeletal power assist robot, which is controlled by the surface EMG of the hip flexor, hip extensor, knee flexor and knee extensor muscle of the subject. We had conducted the exercise programs once a week for three times. Especially, we focused on the activation of Gluteus Maximus muscle. Subjects could have good feedback from surface EMG. The tasks were squatting and walking. The numbers of the exercises were 500 repetitions and 500 steps. A three dimensional motion capture system (VICON 612) was employed to measure the spatial coordinates of the body joints, which were substituted into the numerical model with human dynamic constants. Joint angles, angular velocities, linear velocities, trunk inclination angle and deviation of the center of gravity were calculated. Results Ball velocity at release second after exercise was greater than that before exercise in each subject. Ranges of motion of the shoulder during throwing after exercise were greater than those before exercise of two in three subjects. In contrast, range of motion of the anterior inclination of the trunk during throwing after exercise were less than those before exercise in each subject. Discussion Motor learning is defined as the process of improving motor skills through practice, with long-lasting changes in the capability for responding (Schmidt, 1975). After-effect is a process of the motor adaptation (Huang, 2009). We considered that these kinematic changes were after-effects by the robotic exercise. Because the body weight had been excessive load for the weak muscle, wheel chair users could hardly have chances to activate their hip muscles. We concluded that the robotic exercise can be one of the solutions to these problems References Schmidt, RA. (1975). Psychological Review 82 (4): 225–260. Huang, VS. (2009). HEALTH FITNESS AND DAILY PHYSICAL ACTIVITY LEVELS OF ADULTS WITH MILD AND MODERATE INTELLECTUAL DISABILITIES

CHOW, B.C.1, CHOI, P.2, HUANG, W.3, PAN, C.Y.4

1: HKBU (Hong Kong), 2: HKBU (Hong Kong), 3: HKBU (Hong Kong), 4: NKNU (Taiwan)

Introduction Adults with intellectual disabilities (ID) tend to have low fitness levels and high obesity rate (Grondhuis and Aman, 2013) and they are mostly sedentary (Heller et al., 2011). Therefore, the aim of this study was to determine the health fitness and daily habitual physical activity (PA) levels in a sample of adults with mild and moderate ID living in two supported hostels. All participants work full-time in a shelter workshop which is in the same building with the hostel. While at work, they are mostly in sitting position doing tasks such as stick on product labels and packaging. Methods Sixty-three adults (30 in Hostel A, 33 in Hostel B) with mild (n=19) and moderate (n=44) ID (20 females, 43 males) participated in the study. These baseline health fitness measures were taken by test administrators: height, weight, percent body fat, waist and hip circumferences, sit and reach test, 30-sec bicep curl test, and 6-min walk test (25m distance). Furthermore, each participant wore the accelerometer (GT3X model, ActiGraph, Florida, USA) clipped onto the right waist for 8 consecutive days or 5 consecutive weekdays with one following weekday. They were told to wear it in waking hours except in shower and they were told to resume their usual daily activities during data collection period. Daily PA data were presented in light PA percentage (%LPA) and moderate-to-vigorous PA percentage (%MVPA) based on the accelerometer cut-off counts (Freedson et al., 1998). Results The mean (SD) age of the participants was 44 (6.6) years. There were no differences in mean fitness and physical activity values between mild ID and moderate ID participants as well as participants from two hostels except participants from Hostel B had significantly ($p<.05$) higher %MVPA (1.5%) and MVPA minutes (10.2 min) per day than their counterparts (0.7%MVPA, 5.4 min). Half of these participants are overweight or obese (53%) and a quarter of them are at high health risk (27%) based on the Asian standard for body mass index and waist circumference, respectively. They were very sedentary engaging 31% in LPA and 1% in MVPA of waking time per day. Discussion The sample of adults with mild and moderate ID residing in hostels have poor flexibility and upper arm muscular strength with half of them being overweight and obese. They are sedentary both during at-work hours and after-work hours. We suggest that exercise intervention programs should be offered to this group of special population for the purpose of improving on their general health as well as health-related fitness. EFFECTS OF 12-WEEKS NORDIC WALKING AND XCO WALKING TRAINING ON THE ENDURANCE CAPACITY IN OLDER ADULTS

MORAT, T.1, KRUEGER, J.1, GAEDTKE, A.1, PREUSS, M.2, PREDEL, H.G.3

1: German Sport University Cologne, 2: University Bonn, 3: German Sport University

Introduction With increasing age, endurance capacity declines and can lead to functional problems in everyday life. Several studies already examined the positive effects of various endurance training forms in patient groups and in healthy adults up to 60 years. However, there is a lack of studies that examined the physiological effects of systematic endurance training in healthy older adults, aged 60 years and older. Therefore, the aim of this study was to analyse the effects of Nordic Walking and XCO Walking training on the endurance capacity in older adults. Methods Twenty-three older participants (mean age: 69.9 ± 5.4 years) were randomly assigned to either the Nordic Walking group (NW; n=12, 5 males, 7 females) or the XCO Walking group (XCO, n=11, 4 males, 7 females). Both groups received 8 sessions of technical training before the pre-measurements of physiological parameters. All participants were measured before and after the 12 weeks of endurance training (2 sessions/week, 60 min. per session) with a portable indirect calorimetric device (MetaMax 3B® Cortex, Germany) to examine oxygen uptake (VO₂) and energy consumption during an outdoor field test. Every subject performed the assigned training tool, either Nordic Walking or XCO Walking, on a running track in five progressively increasing speeds (1.0m/s, 1.2m/s, 1.4m/s, 1.6m/s, 1.8m/s, 5 min. per speed, 3 min. rest). In addition, heart rate was recorded and lactate samples collected. Results NW demonstrated a statistically significant ($p<.05$) reduction in energy consumption at 1.0m/s, in lactate concentration at 1.0m/s, 1.2m/s and 1.4m/s after 12 weeks of Nordic Walking training. XCO displayed a statistically significant ($p<.05$) decrease in VO₂ at 1.0m/s - 1.6m/s, in energy consumption at 1.6m/s and in lactate concentration at 1.0m/s - 1.6m/s after 12 weeks of XCO Walking training. Both groups trained with similar percentages in heart rates and indicated no differences in walking speed and total distance within the training sessions. Discussion Both, NW and XCO showed positive effects on endurance capacity in older adults. NW mainly demonstrated few improvements at lower walking speeds, whereas XCO revealed several improvements at low to higher walking speeds. Depending on the

fitness level, training goal and walking speed, both endurance training forms (NW and XCO) are effective to maintain the endurance capacity in older adults. References Preuss M, Preuss P, Mechling H. RELATIONSHIP BETWEEN NURSES' PERSONAL FACTORS AND PHYSICAL ACTIVITY

SINSOONGSUD, T., SINSOONGSUD, W., PIASEU, N.

Faculty of Medicine Ramathibodi Hospital

Do not inintroduction Physical activity is an important component of a healthy lifestyle to reduce a person's risk of developing diseases. Current recommendations for physical activity advocated by the ACSM and also 11th Thai national economic and social development plan are that "all healthy people need moderate to vigorous intensity aerobic or physical activity". To achieve improving levels of physical activity, all sectors including nurses are important factor. The purpose of this research will 1) describe physical activity counseling behaviors of nurses and 2) investigate the relationship between nurses' personal factors and physical activity counseling behaviors toward their patients. Methods This study used a correlational descriptive method. The sample included 170 nurses in outpatient department, Ramathibodi hospital who were selected by using purposive sampling. Data were collected by a self-reported questionnaire on demographic characteristics (gender, age, work experience, exercise frequency and body mass index (BMI)) and physical activity counseling behaviors. Data were analyzed using descriptive and inferential statistics. Result All females with mean age of 38.15 ± 11.29 years. The average of experience 13 years. Half of them (50%) had normal BMI and 51.4% had no underlying disease. Their physical activity behaviors, 46.8% rarely exercised (1-2 times/mo.), 40.5% regularly exercised. Nurses had physical activity counseling behaviors at low level. The correlation analysis with spearman rho method revealed that work experience was positively associated with counseling behavior subscales, respectively. Especially address agenda, assess patient's health and physical activity level, assist patient by provide information for schedule physical activity plan at appropriate level, and arrange follow-up ($r = .300$, $p = .009$; $r = .251$, $p = .031$; $r = .286$, $p = .013$ and $r = .258$, $p = .026$ respectively). Discussion The findings can fundamental data for the administrators to improve and promote nurses' physical activity, and improve nursing's scope of practice in line with the goal of the National Health Development Plan. This will result in increment nurses' counseling behavior about physical activity and realize that physical activity as part of treatment program. References American College of Sports Medicine. PHYSICIANS' PHYSICAL ACTIVITY COUNSELING BEHAVIORS AND PERSONAL FACTORS

SINSOONGSUD, W., SINSOONGSUD, T., PIASEU, N.

Faculty of Medicine Ramathibodi Hospital

Introduction Patients would be more interested in physical activity to stay healthy if advised by their physicians. However, not too much physicians advocates their time for counseling physical activity. Therefore, the aimed of this study was to 1) describe physical activity counseling behaviors of physicians and 2) investigate the relationship between physicians' personal factors and physical activity counseling behaviors toward their patients. Methods This correlational research used purposive sampling, the sample included 96 physicians in outpatient department, Ramathibodi hospital. Data were collected by a self-reported questionnaire on demographic characteristics (gender, age, work experience, exercise frequency and body mass index (BMI)) and physical activity counseling behaviors. Data were analyzed using descriptive and inferential statistics. Results Results revealed that participants were 96 physicians. The 50% males and 50% females with mean age of 29.09 ± 1.72 years. The average of experience 3.80 ± 1.93 years. Most of them (79.2%) had no underlying disease. But they (29.2%) rarely exercised (1-2 times/mo.), (28.1%) sometimes exercised (1-2 times/wk.); only 13.5% regularly exercised. Physicians had physical activity counseling behaviors at moderate level. The correlation analysis with spearman rho method revealed that work experience was positively associated with counseling behavior subscales, respectively. Especially address agenda, assess patient's health and physical activity level, assess patient's belief and knowledge about the health and physical activity, and assist patient by provide information for schedule physical activity plan at appropriate level ($r = .222$, $p = .031$; $r = .210$, $p = .046$; $r = .265$, $p = .01$ and $r = .219$, $p = .033$ respectively). Discussions The findings can fundamental data for the administrators to improve and promote physicians' physical activity, especially increasing exercise in order to enhance awareness and knowledge. Physicians have incremental physical activity counseling behaviors so that they will promote their patients to increase levels of physical activity, in a way that will have an impact on healthy behavior on their patients. REGULAR NORDIC-WALKING TRAINING ENHANCES THE MUSCLE STRENGTH AND BLOOD LEUCINE CONCENTRATION IN OLDER WOMEN - EFFECT OF VITAMIN D.

DZEDZEJ, A.1, MIESZKOWSKI, J.2, PRUSIK, K.3, KORTAS, J.3, KOCHANOWICZ, A.4, SMOLEŃSKI, R.T.5, ANTOSIEWICZ, J.6, ZIEMANN, E.1

1,3,4,5, Gdańsk University of Physical Education and Sport, Gdańsk, 2Kazimierz Wielki University, Bydgoszcz, Poland

Introduction Age-related muscle wasting is accompanied by inflammation process, in which the autophagy-inducing stress protein HMGB-1 is involved. Among factors, that protect against muscle degradation are amino-acid leucine (Breen and Phillips 2011) and vitamin D3 (25-hydroxyvitamin D (25-OH-D) (Girgis, Baldock et al. 2015). Consequently, the aim of this study was to evaluate the effect of Nordic-walking (NW) training and vitamin D3 supplementations on leucine, HMGB-1 concentrations and muscle strength. Methods 70 senior women (68 ± 8 years old) took part in the experiment. The participants were divided into following sub-groups: two completing the Nordic-walking training, supplemented by vitamin D3 (I, $n=23$, 800IU/day; and II, $n=22$, 4000IU/day) and one control (C, $n=15$). At baseline and one day directly after the 12-week training programme blood measurements took place. Concentrations of HMGB-1 and myokines (irisin and IL-6) were assessed. Additionally, mass spectrometry coupled with high performance liquid chromatography was used to measure leucine level. Isometric and isokinetic knee muscle functions (90°) were determined using Biodex System. Results The applied training

programme resulted in a significant rise of leucine in II group (pre 81.9 ± 22.7 vs post $105.4 \pm 40.5 \mu\text{mol}\cdot\text{L}^{-1}$, $p < 0.05$), yet in the I group the increase was much smaller (88.3 ± 42.2 vs post $97.1 \pm 43.0 \mu\text{mol}\cdot\text{L}^{-1}$). Values in C-group did not shift significantly. Isokinetic knee muscle functions in both supplemented groups were improved, however the effect was more pronounced in II-group. No changes in myokines and HMGB-1 were recorded. Still, in all groups a significant, inverse correlation between irisin and HMGB-1 was noted. Discussion Obtained data demonstrate that NW training caused an improvement of muscle functions and this adaptation process was modulated by vitamin D3. These results confirm previous observations that muscle function depends on the vitamin D3 concentration. The shift in muscle strength was accompanied by an increase in blood leucine which is known to stimulate muscle protein synthesis (Breen and Phillips 2011) and this effect is amplified by vitamin D. Conversely, the role of vitamin D in regulation of leucine metabolism and its blood level is not known. Breen, L. and S. M. Phillips (2011). Nutr Metab (Lond) 8: 68. Grgis, C. M., P. A. Baldock, et al. (2015). Mol Cell Endocrinol 410: 3-10. anna.dzedzej@gmail.com

GENDER DIFFERENCES IN BODY WEIGHT LOSS AFTER A SHORT AND MIXED WEIGHT REDUCING PROGRAM

JOFFROY, S., GARNIER, S., LEMOINE-MOREL, S., RIESCO, E., SANGUIGNOL, F., MAURIÈGE, P.

Université Paul Sabatier

Introduction According to the last ObEpi record, 47.3% of French people aged 18 years and over are overweight, and 15% of them are obese (Eschwège et al., 2012). Diet and aerobic exercise are considered the cornerstone of obesity management (Johns et al., 2014). In France, 3-week weight loss programs developed by weight-loss centers and under medical supervision consist in modifying eating and physical activity habits and include psychological counseling. The main objective of this observational and retrospective study was to verify the effect of a mixed weight loss program combining caloric restriction and exercise on body weight and adiposity reflected by body mass index (BMI), in obese sedentary men and women, and to examine the existence of gender differences after weight loss, once the degree of obesity is taken into account. Methods 562 men (42.4 ± 12.2 years) and 781 women (45.2 ± 11.2 years) (NS) received a dietary plan of 1400–200 kcal/day and completed 110 min endurance exercise, 6 days/week during 3 weeks (Lemoine et al., 2007; Riesco et al., 2009). Body weight and BMI were determined before and after the mixed weight loss program. An analysis of variance was used to detect changes in response to the weight-reducing program, between genders and according to the obesity degrees defined by the WHO (1998). Results Body weight and BMI decreased in men (-5.5–2.4 kg; -1.8–0.8 kg/m²) and women (-3.9–1.8 kg; -1.5–0.7 kg/m²) in response to the intervention ($p < 0.0001$). Men with the highest BMI values before the program were also characterized by the greatest body weight loss (-7.2 kg; 2.3, $p < 0.0001$). Irrespective of the obesity degree, the reduction of BMI was higher in men than in women ($p < 0.001$). Discussion Our study shows that a short and mixed weight reducing program has a positive impact on men and women's adiposity. However, this program is more benefit in men than in women. A similar analysis taking into account age classes should be interesting. References Eschwège E, et al. (2015) Diabetes Metab, 41, 55-61. Johns D, et al. (2014) J Acad Nutr Diet, 114, 1557-68. ASSOCIATIONS OF PUBLIC BICYCLE USE WITH TRANSPORT-RELATED AND LEISURE-TIME PHYSICAL ACTIVITY IN TAIWANESE ADULTS

LIAO, Y.

National Taiwan Normal University

Introduction: Although adults have increasingly used public bicycle in urban areas, limited studies have examined the associations between public bicycle use and domain-specific physical activity. Thus, this study examined the associations of public bicycle use with transport-related and leisure-time physical activity in Taiwanese adults. Methods: A random-digit-dialing telephone-based cross-sectional survey was administered to Taiwanese urban adults aged 20-64 years in 2015. Data on public bicycle use (non-public bicycle users, non-regular public bicycle users, public bicycle users) and time spent in transport-related and leisure-time physical activity using long version of the International Physical Activity Questionnaire was obtained from 1068 adults in three urban cities. Adjusted logistic regression was used. Results: The results showed that after adjusting for potential confounders, public bicycle users were more likely to achieve 150 minutes of leisure-time physical activity (odds ratio, OR = 1.67; 95% CI: 1.07-2.60) and transport-related physical activity (OR = 2.00; 95% CI: 1.27-3.16) in comparison with non-public bicycle users. No significant associations were observed between non-regular public bicycle users and physical activity in Taiwanese adults. Discussion: Consistent with previous studies (Molina-Garcia et al. 2013; Rojas-Rueda et al. 2011; Woodcock et al. 2014), public bicycle use is associated with higher levels of physical activity. The results of this study further reveal that the findings that public bicycle use is associated with 150 minutes of domain-specific physical activity. Therefore, encouraging public bicycle use could be a promising way for promoting adults to achieve recommended levels of both transport-related and leisure-time physical activity. References: 1. WORKPLACE HEALTH PROMOTION IN APPRENTICES – SURVEY OF HEALTH STATUS, SUBJECTIVE STRESS AND PHYSICAL ACTIVITY

BIALLAS, B., ZÄHRINGER, M., FROBÖSE, I., WILKE, C.

German Sport University Cologne

Background: The aim of workplace health promotion (WHP) is to promote the health of all employees equally (Conn et al. 2009). This demands an age- and gender-specific targeting. Especially the group of trainees facing many life-phase-specific challenges at the beginning of their career and the requirements of working life encounters their individual resources for the first time. These burdens include stress, a high pressure to perform as well as unaccustomed physical loads. Due to an early and global health promotion a positive influence on health and thus on performance and working capacity of the trainees can be achieved (Reik et al. 2010). Against this background the study sets out the health status of apprentices in Germany and assembles the different design suggestions for integrating holistic WHP in apprenticeship. **Methods:** The resulting data of a survey among trainees from 5 Cologne-based companies (n=447 trainees, aged 16 to 38 years) forms the basis of this study. In this study the information on the perceived health status, subjective stress, the physical activity behavior (GPAQ) and two open questions relating the needs concerning WHP were analyzed. In addition the study compiles challenges faced by trainees and presents successful measures of target-group-specific WHP. **Results:** The perceived health status was evaluated on average as "good" by the majority of the trainees. On average subjective stress was stated as "medium high" ("part-part"), whereby female trainees specify a non-significantly higher stress level than male. No correlation was found between the physical activity level and subjective health status. There was a significant correlation between the activity level and the stress level of the trainees ($r=-.131$). The indicated physical activity level was exceptionally high. Values of men are significantly higher than that of women ($p<.001$). Concerning WHP the trainees primarily ask for movement-oriented offers. **Conclusion:** Especially in the period of training companies still have the opportunity to promote healthy behaviors and thus influence health and long-term ability to work of their employees. Gender-specific health promotion activities are necessary. References Reik R, Woll A, Gröben F, Berndt ED (2010). Arbeitsmed Sozialmed Umweltmed, 45, 640-646. BODY IMAGES IN THE MEDIA AND THEIR EFFECT ON OBESITY AND SPORTS RELATED ATTITUDES OF KINDERGARTEN CHILDREN AND TEACHERS

GEITNER, C.1, DIMITRIOU, M.1, STALLINGER, J.1,2, RING-DIMITRIOU, S.1,2

University of Salzburg

Introduction Media consumption, especially of screen-based media, represents a major leisure activity of children (Kesztyüs et al., 2013), therefore it is to be assumed, that the seen media content influences the attitude and behaviour of media users regarding nutrition and physical activity. This effect was to be determined in the present study with the purpose of enabling kindergarten teachers to modulate the children's media consumption in terms of the two mentioned phenomena. **Methods** With regard to content analysis the Austrian TV programme was screened for formats broadcasted particularly for children in kindergarten age from four to six years. Thereafter the input material got reduced by the criteria episode length (> 15 min) and serial transmission. The remaining broadcasts (n=39) were examined with the use of a system of categories, destined to identify scenes with an inherent reference to sports or nutrition. Of those scenes, nine were chosen to be – solely or in combination with comparable scenes – processed with the transaction approach of Hartmann et al. (2006). **Results** The described procedure culminated in six transaction schemes with different subjects. These included genuine sports categories as team spirit, mental toughness, competition (the latter also featured fairness) and body image related constructs (general body image, stigma and socialization by media). The mentioned schemes were garnished with teaching aids like transcripts or screenshots for the use in praxi. **Discussion** As indicated prefatory, the acquired transaction schemes shall support the media competence of kindergarten teachers by empowering them to cope with inadequate body images in daily educational routines. This could contribute to the prevention of socio-psychological aspects like exclusion or bullying. As these factors account for hypercaloric eating disorders too (Littleton & Ollendick, 2003), their eschewal will also promote a healthy lifestyle. ADIPOSITY AND MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AND HEALTH IN FEMALE RURAL COMMUNITIES

MACHADO RODRIGUES, A.M.1,2, FERNANDES, R.A.3, MASCARENHAS, L.P.4, DUARTE, J.2, VALENTE-DOS-SANTOS, J.2, COELHO-E-SILVA, M.J.2, MOTA, J.5

1Polytechnic Institute of Viseu, (Viseu, PORTUGAL); 2UC (Coimbra, PORTUGAL); 3São Paulo State University, BRAZIL; 4Paraná University, (Curitiba, BRAZIL); 5University of Porto, (Porto, PORTUGAL).

Background: Physically active behaviours occur in contexts that differ between urban and rural settings. Indeed, rural areas are characterized by educational and socioeconomic inequities which have impacted on lifestyles and health of youth, and available research dealing with those adolescent behaviours of rural communities is quite limited. Therefore, the purpose of the present study was twofold; i) to analyse the association between MVPA and the central fat mass of those rural female youth and ii) to assess the proportion of rural adolescents that met the guidelines of moderate-to-vigorous physical activity (>60 min/day of MVPA) in a sample of female adolescents. **Methods:** The sample included 140 girls, 13-16 years of age, from rural regions of the Portuguese Midlands. Weight, height, and waist circumference (WC) were measured. An uniaxial GTIM accelerometer was used to obtain five consecutive days of physically activity (PA) and sedentary behaviour. Cardiorespiratory fitness (CRF) was assessed using the 20-m shuttle run test. Logistic regression analyses were used to test the afore-mentioned associations, adjusted for several potential confounders (i.e. age, CRF, and sedentary behaviour). **Results:** Findings revealed low percentages of active female adolescents who met the international PA guideline - about 24% of the rural girls. After controlling for confounders, inactive female rural adolescents (< 60 min/day of MVPA) were more likely to have higher WC than their active counterparts (OR=1.09, 95% CI 1.03 to 1.15, p=0.01). Inspection of the final regression model also indicated that girls classified as inactive were more likely to be involved in sedentary activities than their active peers. **Conclusion:** The present study indicates majority of rural females failed to meet the current guideline of 60 continuous MVPA per day. In addition, inactive rural adolescents were more

likely to have higher central adiposity than their active counterparts. Future research should extend similar design to both genders assessment to confirm some of these preliminary findings of the understudied rural communities.

PHYSIQUE, PERFORMANCE AND IMMUNOLOGICAL STATE OF INACTIVE OR PHYSICALLY ACTIVE ADULTS

WILHELM, M.1, GARAI, K.1, GYEBROVSZKI, Á.1,4, MISKEI, J.2,3, ERNSZT, D.2,3, PONGRÁCZ, E.J.2,3, KVELL, K.2,3

University of Pécs, Hungary

Introduction: Health in any age group strongly correlates with the individual's lifestyle, especially with physical activity (Tremblay et al, 2011). According to WHO data physical inactivity is the 4th risk factor among deaths, especially in more developed countries. In Hungary sedentary lifestyle is common and overweight, obesity, cardiovascular diseases are major problems in the society. As a consequence ageing is faster in Hungary than it would be expected from biological regression. Regression curve is deeper after the age of 40 years. Among the physiological signs of health problems one important factor is the state of the immune system. According to the literature (Gruver et al, 2007) in healthy young adults the hTrec value in the peripheral blood is measurable between wide ranges (approx. 100-2000 hTrec/ug gDNA). Methods: In the present pilot study volunteer adults (males, 23-25 years) participated in anthropological, performance and immunological measurements. Body composition was calculated from skinfold measurements, physical performance was estimated with the aid of 6 minute walking test and handgrip strength test. The immunological age was calculated from T-cell cycle. Short 150ul peripheral blood was taken from fingertips of healthy young inactive control as well as recreational- and professional-sportsmen (n=5 for each group). Human T-cell excision circle (hTrec) copy number was measured using Taqman chemistry on 3D PCR platform and normalized to genomic DNA. Results: Sedentary controls, as it was expected, had a much higher fat percentage, lower physical performance than subjects in any of the active groups. Control individuals showed lower hTrec levels (218 copies/ug gDNA) compared to recreational- (596 copies/ug gDNA) and professional individuals (647 copies/ug gDNA). Discussion: According to our data physical inactivity inhibits or lowers Tcell level. However, regular sport activity significantly increases objective immune parameters (hTrec levels characterize thymus function) irrespective of the degree of sport-activity (recreational or professional). Since there is only about 10% difference between hTrec levels of the active groups in our study, earlier data showing that in elite sportsmen high chronic stress of the immune system caused by the extreme amount of training renders Tcell maturation in the Thymus is not supported. Altogether immunological ageing strongly correlates with the physical activity level of subjects. References: Gruver AL, Hudson LL, Sempowski GD. (2007) Immunosenescence of ageing. *J Pathol.* 211(2):144-56. PHYSICAL ACTIVITY IN A COLLEGE COMMUNITY: A PILOT STUDY

RIDDELL, N., BASKERVILLE, R., CASTELL, L.

Green Templeton College, University of Oxford, United Kingdom

Background: Regular physical activity has multiple health benefits, including reduced cardiovascular disease and Type 2 diabetes. Despite this many people fail to meet the WHO recommendation of 150min/wk. Physical activity at work, when feasible, contributes to overall levels, but can be difficult to recall accurately. This pilot study aimed to evaluate levels of physical activity and inactivity in a university community, using self-reported vs. accelerometer-measured physical activity. Methods: Ethical permission was given to recruit staff, students and academics (aged 18-20) in a university college (n=107; 52M, 55F). Pre- and post-study questionnaires were completed on activity, mood, sleep and anthropometrics. Participants undertook usual work and home activities for 7 days, wearing FitBit One accelerometers with displays concealed. Accelerometer data was categorized into bands of varying intensity as activity counts per minute (cpm): sedentary (<100 cpm), light intensity activity (100-1951 cpm), or MVPA (>1952 cpm). Daily summaries were calculated and overall step counts estimated. Metabolic equivalents (METS) were calculated relative to 1 MET being the energy expenditure of sitting quietly at rest. Results: Average time spent walking, in working hours, was 1.49 hrs/day. Daily step counts were not significantly different between students (7939 steps) and staff (8580 steps) and were irrespective of gender. There was poor correlation overall between measured activity and self-reported activity or pre-study activity habits. However, while males more accurately predicted activity levels ($M=0.452$ $P=0.001$; $F=0.071$ $P=0.336$), females reported more accurately retrospectively ($F=0.176$ $P=0.145$; $M=0.047$ $P=0.382$) despite similar activity levels; more active participants estimated weekly totals less accurately (-0.599 $P=0.001$). The two most active age bands were 20-30 and 51-60 yrs. Sleep quality was significantly better in more sedentary individuals (0.274 $P=0.007$). Obese and underweight participants reported activity levels more accurately. Average daytime sedentary time was 6.47 hrs, although data on lengths of inactivity periods was lacking. Participant acceptability rating for device use was 87%. Discussion and Conclusions: Physical activity levels varied little across all groups and ages, indicating that the work environment influenced activity behaviour. Those participants involved in club, university or national sport (outside work) all reported that their sport had a positive impact on their working life. All groups achieved healthy levels of activity, despite significant time spent sedentary. There were significant differences between self-reported and actual physical activity levels. Future promotion of workplace physical activity may be compromised unless sedentary behaviour is concurrently monitored with objective monitoring techniques. The FitBit One used cost a relatively minimal amount and was acceptable to participants. Similar accelerometers may be appropriate for GPs who monitor patient activity in "at risk" populations.

THE EFFECTS OF YOGA TRAINING ON BODY COMPOSITION AND BLOOD BIOMARKERS IN WOMEN OFFICE WORKERS

PHANGJAEM, M., TSAI, S.C., KAU, M.M., HUANG, F.Y.

UNIVERSITY OF TAIPEI, NATIONAL TAIPEI UNIVERSITY OF NURSING AND HEALTH SCIENCES

Yoga, a traditional exercise in India, has been shown that it can benefit fitness and health. Yoga has become a popular alternative of exercise regimes and many therapies to enhance physical well-being. However, the effect of yoga training on blood biomarkers is still unclear. To investigate the effects of 12-weeks yoga training on physical fitness and blood biochemical marker in women workers, ten women office workers (age 39.80 ± 8.48 yrs, height 160.19 ± 4.40 cm, weight 58.21 ± 7.84 kg and BMI 22.62 ± 2.13 kg.m $^{-2}$) were recruited from Taipei urban area. All subjects completed yoga training of 1 h/wk for 12 weeks including; warm-up 5 min, training 50 min with over 75% heart rate reserve and break 5 min. Physical Before and after 12 weeks training, all subjects were asked to complete measurement of fitness and blood biochemistry. Index of physical fitness included flexibility and body composition (Dual-energy X-ray absorptiometry, DEXA). Blood biochemical parameters included total cholesterol (TC), high-density lipoprotein (HDL), low-density lipoprotein (LDL) and triglyceride (TG). Data differences between before and after training were analyzed by using paired t-test. Statistical significance was accepted at $p < 0.05$. This study found that, after 12-weeks yoga training, the whole body bone mass increased significantly ($p=0.01$), both

of body fat mass ($p<0.05$) and glycohemoglobin (HbA1c) decreased significantly ($p<0.05$). The other parameters including total TC decreased by 4%, TG decreased by 18%, and HDL decreased by 9%. LDL and fasting blood glucose only slightly increased, but there were no difference. In conclusion, yoga training could enhance the improvement of body composition and long term control of blood glucose. Regular and consistent Yoga training could get more health benefit for women office workers.

ANALYSIS OF MUSCLE OXYGENATION PARAMETERS DURING CYCLING: INFLUENCE OF SITE AND COMPARISON OF DIFFERENT COMMERCIAL NEAR-INFRARED SYSTEMS

KOHL-BAREIS, M., RIEDEL, N., LUKANOWSKI, E., REIMANN, A.

RheinAhrCampus, Univ. of Applied Sciences Koblenz, Germany

Introduction Near-Infrared Spectroscopy (NIRS) is widely used as a non-invasive tool for the analysis of muscle oxygenation during exercise with the oxygen saturation and haemoglobin content of the microcirculation being the main parameters [1]. For the widespread application of NIRS with commercial instruments which differ in e.g. wavelengths, light source – detector distance and algorithm questions of quality control and standardization are of great concern as well as variations of parameters with site on larger muscles. Methods Two commercial NIRS instruments (NIRO-200NX, Hamamatsu GmbH, Germany; moorVMS-NIRS, Moor Instruments Ltd., UK) are based on similar technology (light in the wavelength range 750 nm and 850 nm, spatial resolved spectroscopy) were used, each with two probes placed on the site of vastus lateralis of both legs of 12 healthy subjects. Muscle oxygen saturation and total haemoglobin concentrations during cycling (incremental power steps of 30 W and 2 min duration; cadence 80 bpm) were analysed. Adipose thickness was measured by ultra sound. Results A decrease in oxygenation was measured in all subjects with both instruments on all sites. The analysis shows that within error margins both commercial instruments deliver the same values of oxygen saturation on contralateral sites. Within subject variability of oxygen saturation with the probe placement (central to distal site of v. lateralis) were larger than between the two instruments. Due to differences in the algorithms, only relative changes in total haemoglobin concentrations can be analysed. With maximal exercise power the oxygen saturation decrease by about 25 %. The correlation coefficient for the oxygen saturation of the two system was > 90 %, within errors the correlation was the same when comparing the different sites and legs. Correlation of haemoglobin concentrations was somewhat lower Discussion There is no gold standard for the evaluation of haemoglobin oxygenation and concentration of the microcirculation of larger muscles and therefore the evaluation of NIRS parameters can only be achieved by comparison of different measurement systems on tissue during physiological conditions. The main finding is that the oxygenation parameters of both commercial systems agree within error margins which are set mainly by physiological variations within the muscle and different legs. HOW COULD THE PINCH FORCE MVC BE INCREASED MORE WITH A TRAINING COUPLED WITH PAIRS OF WEAK TMS PULSES?

ONO, K.1, SATO, D.1, YAMASHIRO, K.1, KURABE, Y.1, YAMAZAKI, Y.1, NURUKI, A.2, MARUYAMA, A.1

1. Niigata University of Health and Welfare (Niigata, Japan) 2. Kagoshima University (Kagoshima, Japan)

Introduction Force MVC can be improved by muscle hypertrophy and by recruitment of volitional drive from motor cortex. We showed that left pinch force MVC increased by 16.5% from 8.8 kg at initial MVC to the last MVC after the 4 alternate days of training coupled with pairs of threshold TMS pulses. Short interval intracortical inhibition (SICI) was significantly less effective, whereas short interval intracortical facilitation (SICF) was more effective after the last training day in the TMS group and it was concluded that brief synchronization of corticospinal output during MVC training was an effective way of improving central drive to pinch muscles (ECCN in Brno, 2015). We examined how the corticospinal output induced by pairs of threshold TMS pulses would increase pinch force MVC and how long it could take to level off the force MVC. Methods TMS group of subjects ($n=7$) received training on alternate days with superimposed TMS pulses until level off in right pinch force MVC was observed, followed by measurement of the force MVC without TMS about 2 weeks. They performed 4 brief sets of MVC training separated by 5min rest. Each set consisted of 3 MVCs (2s duration) separated by 1min rest. TMS group received a pair of TMS pulses superimposed on each MVC and control group ($n=7$) did not receive any stimulation. Stimulus intensity of pairs of weak TMS pulses was 100% of resting motor threshold at 1.5ms of interstimulus interval (ISI) (Ziemann et al. 1998). Results Pinch force MVC in TMS group started about 10.1 kg on average and reached the level off by 8-10 alternate days of training. The force MVC increased by about 33% through training with TMS pulses. Force MVC in control group started about 9.4 kg showed about 15% increase during almost same training period as that of TMS group. After training, force MVC kept almost constant the last value of force MVC with TMS until 5-6 alternate days. Discussion Addition of the pairs of weak TMS pulses to force MVC training could contribute to the improvement of the recruitment of volitional drive from motor cortex to muscles for pinch tasks. It is likely that the increased SICF provides the indication of the increased excitability of excitatory interneuron and addresses the possibility of the plastic changes to synchronized corticospinal output because of almost same force MVC as the force increased by MVC with TMS. THE EFFECT OF PREVIOUS STRAIN INJURY ON REGIONAL NEUROMUSCULAR ACTIVATION WITHIN RECTUS FEMORIS

KUBO, Y.1,2, WATANABE, K.3, NAKAZATO, K.1, HAKKAKU, T.1, KEMURIYAMA, S.1, KOYAMA, K.2, SUZUKI, M.1, HIRANUMA, K.1

1: Nippon Sport Science University (Japan), 2: Tokyo Ariake University of Medical and Health Sciences (Japan), 3: Chukyo University (Japan)

Introduction Rectus femoris (RF) strain injury occurs during actions such as kicks or splint. The previous study suggested region-specific functional role of the RF, i.e., most part of RF plays as knee extensor and the proximal regions of RF mainly play as hip flexor (Watanabe et al., 2012). The aim of this study is to investigate whether RF strain injury affects the region-specific functional role. Methods The subjects

included seven Japanese collegiate soccer players with a history of unilateral RF strain injury. Physical profile and injury data were obtained by questionnaire. Magnetic resonance imaging (MRI) was used to obtain T1-weighted thigh images. Maximal voluntary contractions were measured during bilateral isometric knee extension and hip flexion with 24 multi-channel surface electromyography (SEMG) and Root Mean Square (RMS) was calculated (Watanabe et al., 2012). RMS values of the hip flexion were normalized by RMS values of the knee extension for each electrode pair. In addition, normalized RMS values were divided into proximal, middle, and distal regions. Normalized RMS values compared each channel bilaterally and three regions of each leg using non-parametric tests. The significance level was accepted as < 0.05 . Results All subjects sustained RF strain injury more than a year ago. Pseudocysts remained in all injured legs. There were significant differences between the most proximal channels in injured and uninjured legs in normalized RMS values (1.03 ± 0.38 vs 1.52 ± 0.32 , $p < 0.05$). There were significant differences between proximal and distal channels of injured legs in normalized RMS values (1.06 ± 0.39 vs 0.59 ± 0.20 , $p < 0.05$). Moreover, we identified significant difference between not only proximal and distal channels but also proximal and middle channels in uninjured legs (1.25 ± 0.30 vs 0.70 ± 0.19 , 1.25 ± 0.30 vs 0.76 ± 0.16 , respectively, $p < 0.05$). Discussion In this study, the region-specific functional role of the injured leg was disordered. Opar et al. reported that SEMG activity in the previously injured biceps femoris (BF) long head was lower than in uninjured BF. Strain injury might reduce the SEMG activity. Additionally, lower levels of SEMG activity might be induced by disorder of the region-specific functional role. In conclusion, previous RF strain injury might affect the region-specific functional role. References Opar DA, Williams MD, Timmins RG, Dear NM, Shield AJ. THE EFFECTS OF MYOFASCIAL TRIGGER POINT RELEASE ON THE FORCE & POWER PRODUCTION OF THE LOWER LIMB KINETIC CHAIN

DEVEREUX, F., KINSELLA, S., BYRNE, P., O'ROURKE, B.

Institute of Technology Carlow

Introduction: Recently, dry needling has become an increasingly popular treatment method for myofascial pain in athletes. However, the majority of studies have investigated its effect on pain and other subjective measures, with very little research considering its impact on function and performance. Previous research has shown that the presence of myofascial trigger points (MTrPs) alters the movement patterns in the shoulder girdle, which can be restored to typical presentation after treatment¹. Thus, it stands to reason that the lower limb may be similarly affected as jumping, which is a major component of field sports, requires complex and efficient movement patterns to be executed optimally². Several factors can influence jump performance including; tight mobilising or weak stabilising muscles, and the efficiency of the bi-articular muscles to transfer force across the joints during the movement. The aim of this study is to investigate if MTrP release in the lower limb kinetic chain can improve jump performance through alleviating the functional impairments associated with MTrPs. Methodology: Sixty male field sport athletes were subject matched into 4 groups; control (no intervention) (group 1), rectus femoris needling (group 2), gastrocnemius needling (groups 3) and both rectus femoris & gastrocnemius needling (group 4). All subjects performed 5 loaded squat jumps (0%, 10%, 20%, 40%, 60% body weight), which were recorded using the iPhone (Apple Inc., USA) based app 'MyJump' and analysed to develop a force-velocity profile. This served as a baseline measurement. Subsequently, a minimum of two days later, each subject received their respective intervention and repeated the jump test straight away. Subjects then returned at 48h, 72h and 96h to repeat the test. All subjects performed a standard warm up prior to each test. Percentage changes in the force-velocity profile between sessions was calculated for all subjects for comparison purposes. Results: It is hypothesized that myofascial trigger point release will improve squat jump performance compared to control. With the most significant increase being observed in the both rectus femoris and gastrocnemius intervention group. Results are pending and expected in May 2016. Conclusion: The findings of this study will provide a performance based benefit to what has traditionally been a therapeutic based intervention in myofascial trigger point release.

VOLUNTARY ACTIVATION OF THE QUADRICEPS MUSCLE IS IMPAIRED FOLLOWING A 2000-M ROWING TIME-TRIAL IN ELITE ROWERS

HUSMANN, F., GUBE, M., FELSER, S., WEIPPERT, M., MAU-MOELLER, A., BRUHN, S., BEHRENS, M.

University of Rostock, Germany

VOLUNTARY ACTIVATION OF THE QUADRICEPS MUSCLE IS IMPAIRED FOLLOWING A 2000-M ROWING TIME-TRIAL IN ELITE ROWERS Introduction The quadriceps muscle is identified as a major contributor to rowing propulsion and performance [1]. Central and peripheral impairments differ according to the fatiguing task being performed [2]. However, little is known about these alterations following a 2000-m rowing time-trial (TT). Therefore, this study investigated the impact of the TT on neuromuscular function of the quadriceps muscle in elite rowers. Methods Seven elite-level rowers (3 men, 4 women, age: 19 ± 6 yrs) performed a 2000-m TT on an indoor rower or a time-matched rest period (control). Neuromuscular function of the quadriceps muscle was assessed prior to and immediately after the TT and control using electrical stimulation of the femoral nerve. Isometric (MVTiso) and concentric maximum voluntary torques (MVTcon) as well as voluntary activation (%VA) during both contraction modes and peak twitch torques (paired stimuli at 100 Hz and 10 Hz) of the quadriceps muscle were analyzed. Furthermore, maximal M-waves (Mmax) and normalized root mean square of the EMG signal were calculated. To test the effect of the TT, two-way (time x condition) repeated-measures ANOVAs were conducted for each variable. Results Significant time x condition interactions were found for MVTiso ($p = 0.006$), MVTcon ($p = 0.008$), %VAiso ($p = 0.013$) and %Vacon ($p = 0.034$). Post-hoc tests revealed significant declines of MVTiso (-17.9%, $p = 0.007$) and MVTcon (-13.3%, $p = 0.003$) following the TT. MVT decrements were accompanied by reductions in %VAiso (-16.8%, $p = 0.013$) and %Vacon (-13.6%, $p = 0.037$). No significant changes were observed in Mmax, paired stimuli peak twitch torques at 100 Hz and 10 Hz and normalized root mean square. Discussion Fatigue-related reductions in MVTiso and MVTcon of the knee extensors were observed which were mainly caused by an impaired %VA. Thus, the results indicate a development of central fatigue following the TT. It has been suggested that the reduced %VA in a fatigued state could protect the muscles from metabolic catastrophe presumably mediated by central projections of group III and IV muscle afferents [3]. Furthermore, the absence of peripheral fatigue might be due to the time lag between the TT and measurement ($3:45 \pm 0:02$ min). This observation is in accordance with Froyd et al. [4], who reported substantial recovery of peripheral fatigue within this time period. 1. Soper C, Hume PA. (2004). Sports Med, 34, 825-48. 2. Enoka RM, Stuart DG. (1992). COMPRESSION WITH VANTAGE SUPPORTER ON THIGH PREVENTS HAMSTRING MUSCLE CRAMPS AFTER MAXIMUM CONTRACTION

TANIMOTO, M., SHIROSAY, M.

Kinki University

Introduction Vantage supporters that compress muscles are known to have some advantages such as prevention of muscle strain injury, relief from injury pain, and prevention of muscle cramps. These advantages, however, are hard to verify in terms of specific effects. In this study, we discovered a hamstring muscle cramp induction method. We investigate the effect of compression with a vantage supporter in preventing muscle cramps using this muscle cramp induction method. **Method** Ten healthy men performed maximum voluntary isometric knee flex contraction (knee flex MVC) at 70 degree knee angle in a prone I position for 5sec., relaxed in this angle for 5sec. and relaxed in full extended angle with and without vantage supporter compression as a muscle cramp induction experiment. The vantage was wrapped around the thigh and compression pressure was regulated at 40-50mmHg. Hamstring muscles [biceps femoris long head (BFL), biceps femoris short head (BFs), semitendinosus muscle (ST), semimembranosus muscle (SM)] activity levels during relax phase after maximum contraction and subjective assessment for hamstring muscle cramp (5: hard, 4: ordinary 3: somewhat, 2: near, 1: none) were used as an evaluation index of muscle cramps. The subjects performed knee flexion isotonic exercise [10-repetition maximum (10RM) × 5 sets] 24 hours prior to this muscle cramp experiment in order to induce hamstring muscle cramps. The muscle cramp experiments with and without compression were executed in a random order. The experiments were separated by intervals of over 30min. Result Root-mean-square (RMS) of electromyography (EMG) in average 4 hamstring muscles during relax phase after maximum contraction normalized by MVC without compression was derived as evaluation index. This RMS value with 40-50mmHg compression was significantly lower than that without compression (0.10 ± 0.11 vs 0.23 ± 0.16). Subjective assessment for hamstring muscle cramps with compression was significantly lower than that without compression (1.8 ± 0.8 vs 4.6 ± 0.6). There were no significant differences either in knee flexion force or RMS of EMG in knee flex MVC between with and without compression. There were no significant differences in RMS of EMG either at rest before knee flex MVC or at rest after knee full extend between with and without compression. Conclusion 40-50mmHg compression with vantage supporter on thigh prevents hamstring muscle cramps after maximum contraction. References Hoffman MD1, Stuempfle KJ2. Sports Med Open. Introduction The molecular basis of muscle fiber functional diversity and plasticity is to a large extent encoded by expression of distinct types of myosin heavy chain (MHC) isoforms in skeletal muscle. However, it is uncertain whether change in the MHC profiling is prerequisite for exerting any functional effect on contractility of muscle fibres of motor units (MUs) at the early stage of resistance training. **Methods** In this study we investigated expression of MHC isoforms, and electrically evoked twitch time characteristics, maximum force generation capability, and fatigability of slow, fast resistant to fatigue (FR) and fast fatigable (FF) MUs in rat fast-type medial gastrocnemius muscle after 5 weeks of voluntary progressive resistance exercise (squat type). **Results** After exercise muscle MHC isoform expression did not change significantly. Maximum force increased in slow (49%) and FR MUs (33%) but not FF MUs. Twitch contraction time was shortened in slow and FR MUs while half-relaxation time only in FR MUs. During the standard fatigue test, FF MUs fatigued less during initial 15 seconds. In FR MUs force was potentiated during the first minute of activity. **Conclusions** After 5 weeks of resistance exercise modifications in the contractile regulatory and energy metabolism systems of MU muscle fibers occur before any significant transition in muscle MHC isoforms is detected. HEMATOLOGICAL CHANGES INDUCED BY MARATHON RACE IN DIFFERENT THERMAL ENVIRONMENT

OLIVEIRA, R.A., JUNIOR, E.P.S., SIERRA, A.P.R., BENETTI, M.P., LIMA, G.H.O., SILVA, E.D., ALMEIDA, S.S., KISS, M.A., SIERRA, C.A., PESQUERO, J.B., GHORAYEB, N., CURY-BOAVENTURA, M.F.

1Cruzeiro do Sul University (São Paulo), 2University of São Paulo (São Paulo), 3Universidade Federal de São Paulo (São Paulo), 4Dante Pazzanese Institute of Cardiology (São Paulo),

Introduction Prolonged exercise in thermally stressful environmental conditions may impair the hematological parameters and promote hemolytic anemia. Therefore, the aim of this study was evaluate hematological parameters after race in different thermal environments. **Methods** Forty male endurance runners participated in this study. Blood samples were collected 24 h before, immediately after, 24 h after, and 72 h after the São Paulo International Marathon 2014 (20 runners, 21-29°C and relative humidity of 53%) and Marathon 2015 (20 runners, 16-18°C and relative humidity of 82%). The following parameters were carried out: iron, ferritin, total and unconjugated bilirubin, total erythrocyte count (TEC), hemoglobin (Hb), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and corpuscular hemoglobin concentration (CHCM). **Results** Blood iron levels elevated 24 h after the race and iron and ferritin blood levels reduced 72 h after the race in both thermal environment. TEC, Hb and Ht decreased 24 h after race and remained low 72 h after race in both thermal conditions. We not observed changes on MCV and MCH and CHCM increased after race just in hot environment. The total and unconjugated bilirubin increased 24 h after race and returned to basal levels 72 h after race in temperate and hot environment. Discussion Long-distance running induces oxidative stress and systemic inflammation followed by hematological changes increasing the risk to hemolytic anemia (Sureda et al., 2015; Reid et al., 2004; Habe et al., 2015). Previous studies also demonstrated that mechanical stress induced hemolysis (Robach et al., 2014). Prolonged exercise in hot environment can induce progressive dehydration, increase blood flow and a reduction of blood volume (Sureda et al., 2014). In our study we observed just an increase on CHCM in hot

environment. In this study, we demonstrated impairment on hematological parameters indicating the high risk to hemolytic anemia in long-distance runners. The physiological adaptation, acclimatization may be contributed to the same hematological response in different environments. References Reid SA, Speedy DB, Thompson JM et al.. THE COMBINED EXPOSURES BETWEEN INTERMITTENT HYPOXIA AND COLD IS ASSOCIATED WITH ENHANCED RESPIRATORY LONG-TERM FACILITATION AND PERIPHERAL CHEMOREFLEX SENSITIVITY WITH AN Elevated CO₂ IN HUMAN

FUKUOKA, Y., KIMURA, A., HOJOY, T., NAKAMURA, M., EBINE, N.

Doshisha University

Introduction: Long-term facilitation of ventilation (vLTF) following acute intermittent hypoxic (IH) maneuver is only expressed when CO₂ maintained above isocapnic levels in humans (Harris et al. 2005). vLTF might be characterized by promoting the serotonin neural pathways of respiratory plasticity (Gonzalez-Rothni et al., 2015). We investigated effects of cold in ventilatory responses at IH exposure with an elevated CO₂. Methods: Nine healthy males (years: 22.6±3.3yrs) experienced a series of IH breathing the hypoxic air (FIO₂: 10%) and the room air (FIO₂: 21%) seven times alternating every four minutes with two temperature conditions: normal temperature (34 deg) and low temperature (11 deg). Subjects wear the perfused suits. The rectal temperature (Tre) and four skin temperatures (chest, upper arm, thigh and calf) were measured to calculate mean skin body temperature (T_b), temperature (T_{sk}), respectively. Breath-by-breath ventilation (VE) and O₂ saturation (SpO₂) were monitored by the metabolic chart. End-tidal CO₂ pressure (PETCO₂) was maintained at basal level (isocapnia) and higher level (+4 mmHg, hypercapnia). Results: Low temperature induced the unchanged Tre and the remarkable decreased T_{sk} and T_b ($p < 0.01$), otherwise normal temperature made unchanged Tre and T_{sk} throughout the experiment. The VE was fluctuated at low temperature during IH with the occurrence of vLTF independent of CO₂. Greater VE response at low temperature was also gradually increased at hypercapnia compared with isocapnia. Acute hypoxia ventilatory responsiveness (HVR: Δ VE/ Δ SpO₂) tended to be increased with the repeated hypoxia. A significantly reduction in T_b at low temperature was related to the augmented VE during isocapnic IH ($r = 0.88$, $p < 0.05$), however, the hypercapnic IH would depress the slopes of this relationship. Discussion: At normal temperature, the enhancement in vLTF could appear following IH maneuver at an elevated CO₂ in human. Besides this, further progression HVR by cold exposure could produce the tight linkage between T_b and VE. On the other hand, this relationship was inhibited by hypercapnia associated with the enhanced basal VE. In conclusion, the IH induced the repeated enhancement in the VE response with long-term facilitation associated with cold and an elevated CO₂. Hypoxic induced VE response could be linearly enhanced by cold exposure. References: Harris DP, Balasubramaniam A, Badr MS, Mateika JH (2006) Am J Physiol 291, R1111-1119. ENERGY COST DURING WALKING AT SIMULATED HIGH ALTITUDE IN HEALTHY YOUNG MALE LOWLANDERS

HORIUCHI, M., HANNA, Y., ABE, D., FUKUOKA, Y.

Mt. Fuji Research Institute

Introduction: Oxygen consumption (VO₂) during walking, per distance unit (Cw; ml kg⁻¹ m⁻¹), has been shown to have a u-shaped relationship, indicating that there is a particular gait speed that minimizes the Cw in each individual, which is known as economical speed (ES) (Horiuchi et al., 2015). However, little information is available regarding an individual's ES at simulated high altitude. Methods: Twelve healthy young male subjects, with a mean age of 24±2 years, height of 174±2 cm, and body weight of 70±3 kg (mean±SEM), participated in this study. They walked on a treadmill at six gait speeds, from 40–98.3 m min⁻¹ (each gait speed lasted for four min), at a level gradient under normoxia (room air), moderate hypoxia (15% O₂), and severe hypoxia (11% O₂), respectively. Muscle deoxygenation (HHb) of the vastus lateralis muscle was also measured using near-infrared spectroscopy. Results: The ES under severe hypoxia was significantly slower than under either normoxia or moderate hypoxia ($P < 0.05$, respectively), while no differences were observed between normoxia and moderate hypoxia (80.5±1.2 m min⁻¹ in normoxia, 78.3±1.2 m min⁻¹ in moderate hypoxia, and 73.4±1.1 m min⁻¹ in severe hypoxia). In contrast, there were no differences in the Cw at any gait speed among the different oxygen levels. Relative changes in HHb between the standing baseline and the last minute of gathered data at a gait speed of 98.3 m min⁻¹ were significantly related to an individual's ES when the data were pooled ($r=0.441$, $P=0.007$, $n=36$). Discussion: It was reported that VO₂ showed a stable phase after 1~2 min at the onset of exercise, with no differences between normoxia and moderate hypoxia, despite a relatively higher exercise intensity under hypoxia (DeLorey et al., 2004). This may suggest that hypoxia per se did not affect the steady state of the whole body VO₂, which resulted in unchanged Cw in the present study. Moreover, HHb profiles could explain an individual's ES by ~20% ($r^2=0.194$) at high altitude. Thus, muscle O₂ extraction evaluated by HHb (Grassi et al., 2003) can be a potential factor for determining an individual's ES. Taken together, our results suggest that acute severe hypoxia slowed the ES ~ 8 % with unchanged Cw among conditions. Furthermore, these alterations of ES can partly account for local muscle O₂ extraction profiles. References Horiuchi M, Endo J, Horiuchi Y, Abe D (2015) J Exerc Sci Fitness 13, 79-85. EFFECT OF ENDURANCE TRAINING ON VENOUS COMPLIANCE IN YOUNG SUBJECTS

SAITO, M.1, SIMODA, K.2, OTA, M.2, OUE, A.2

Toyo University

Introduction The venous system plays an important role in hemodynamic control because venous vessels have high distensibility and contain 60-70% of whole blood at resting condition. Ageing and/or the lower physical activity is thought to associate with the increased stiffness of veins (Hernandez et al. 2004; Young et al. 2006), which might cause the cardiovascular disease (e.g. hypertension) (Olsen and Lanne 1998; Safar and London 1987). Many studies have reported the effect of exercise training on arterial function, although the information about venous function is a few. Thus, the purpose of this study was to investigate whether endurance training improves the venous compliance in young subjects. Methods Nineteen subjects participated in this study (training group (TRA): n = 8, control group (CON): n = 11). Training program consisted of cycling exercise at 60% HR_{reserve} for 40-min 3 times a week for 8 weeks. Forearm and calf venous compliance was measured on subjects in the supine position by inflating a venous collecting cuff placed around upper arm and

thigh 60 mmHg for 8 min and then decreasing cuff pressure to 0 mmHg at a rate of 1 mmHg/s. Forearm and calf venous compliance was determined using the first derivation of the cuff pressure-venous volume relation obtained during cuff pressure reduction (compliance = $\beta_1 + 2\beta_2 \times$ cuff pressure). In addition, venous capacitance and maximal venous outflow were also assessed. Results In TRA, cuff pressure-calf venous volume curve shifted to upward significantly after training ($P < 0.05$), although cuff pressure-calf venous compliance did not alter. In addition, calf venous capacitance was 18% greater after training ($P < 0.05$), but maximal venous outflow did not differ before and after training. Venous functions of forearm were not changed by training. In CON, all parameters did not alter. Discussion Endurance training for 8wk in our study caused the increase in venous capacitance but did not improve venous compliance. This result is not consistent with previous studies which have reported that venous compliance is greater in chronic endurance exercise-training men than sedentary (Hernandez and Franke 2004; Monahan et al. 2001). Based on these, our training program might be too short and/or too mild for the young to improve venous compliance. Reference Hernandez JP, Franke WD. (2004). J Appl Physiol 97: 925–929. EXERCISE INCREASES SKIN-GAS NITRIC OXIDE CONCENTRATIONS EMANATING FROM RAT TAIL

UTSU, Y.1, YOSHII, Y.1, KATO, H.1, MATSUURA, K.1, TAMURA, K.1, TAKAI, S.1, OHKUWA, T.1, TSUDA, T.1, ITOH, H.1

Nagoya Institute of Technology

Introduction Exercise increases nitric oxide (NO) synthesis in the arterial vessels because increasing blood flow stimulates vascular endothelial cells by increasing shear stress (Ulrich et al, 1997). Previous studies have demonstrated that exercise training increase the plasma nitrite (NO₂-) and nitrate (NO₃-) (D.S. Xiao and Z.M. Qian 2000). On the other hand, no effects of exercise training on plasma NOx (NO₂- + NO₃-) concentrations also have reported (Rin et al. 2013). Moreover, there are very little data concerning the changes in skin-gas NO concentrations during exercise and the effects of exercise training. Therefore, the aim of the present study was to investigate skin-gas NO concentrations emanating from rat tails before and after exercise and to confirm differences in plasma NO concentrations between sedentary and trained rats. Methods Wister male rats (7 weeks of age) were divided into sedentary and training group. Exercise training was carried out on treadmill (2-15 m/min) for 30min twice a week. The skin-gas samples were obtained by covering the tail for 10 min with a polyethylene bag (Iwatani material, Tokyo, Japan) in which pure nitrogen gas (120mL) was introduced, and collected (100mL) in a sampling bag (Tedlar bag; GLScience, Tokyo, Japan) at rest and after exercise. The skin-gas NO concentration was measured by a chemiluminescence analyzer (Pico-Device Co., Ltd., Nagoya, Japan). At 15-16 weeks of age, rats were anesthetized and blood was taken immediately transferred into a vacuum tube containing heparin. The plasma NO concentration was analyzed with Nitric Oxide Assay Kit (BioAssay Systems, USA) by microplate reader ($\lambda=540$ nm). Results Skin-gas NO concentrations increased significantly ($p<0.05$) after exercise compared to the resting values in trained rats through whole experiment periods. Furthermore, significantly higher plasma NO concentrations were observed in trained than sedentary rats. Discussion Increased skin-gas NO concentrations after exercise compared to resting values observed in this study has indicated increased NO synthesis produced by endothelial nitric oxide synthase (eNOS) in the arterial vessels and (or) induced NOS in tissues during exercise. Furthermore, significantly higher plasma NO concentrations in trained rats have suggested that repetitive exposure to haemodynamic and shear stress in trained rats might up-regulate NO dilator system by increasing eNOS activity at rest. THE INFLUENCE OF PHYSICAL ACTIVITY DURING PREGNANCY ON MATERNAL, FETAL OR INFANT HEART RATE VARIABILITY: A SYSTEMATIC REVIEW

SATTLER, M.C.1, WATSON, E.D.2, RUF, W.1, TITZE, S.1, VAN POPPEL, M.1,3, DIETZ, P.1

University of Graz

1: University of Graz, Austria 2: University of Witwatersrand, South Africa 3: VU University Medical Centre, Amsterdam, the Netherlands Introduction Physical activity (PA) during pregnancy has been shown to be associated with several positive effects for mother, fetus, and offspring (Clapp, 2003; Dye et al., 1997). Heart rate variability (HRV) is a noninvasive and surrogate marker to determine fetal overall health and the development of fetal autonomic nervous system. In addition, it has been shown to correlate strongly with maternal HRV and is significantly influenced by maternal behavior (Graca et al., 1991). However, the influence of maternal PA on HRV has not yet been systematically reviewed. Therefore, the aim of this systematic review was to assess the influence of regular maternal PA on maternal, fetal or infant HRV. Methods A systematic literature search following a priori formulated criteria of studies that examined the influence of regular maternal PA on maternal, fetal or infant HRV was performed in the databases Pubmed and SPORTDiscus. Quality of each study was assessed using the standardized Quality Assessment Tool for Quantitative Studies, QATQS (Effective Public Health Practice Project, 2008). Results In total, 124 articles were screened by title and abstract. Of these, nine articles passed the a priori formulated criteria and were included into the present systematic review: two intervention studies, one prospective longitudinal study, and six post-hoc analysis of subsets of the longitudinal study. Of these articles, four assessed maternal HRV, five fetal HRV, and one infant HRV. Four of five articles regarding the influence of maternal PA on maternal HRV indicated contrary results. Four of five articles regarding the influence of maternal PA on fetal HRV showed increases of fetal HRV on most parameters depending on maternal PA. The overall global rating for the standardized quality assessment of the articles was moderate to weak. Discussion Based on the current evidence available, our overall conclusion is that the hypothesis that maternal PA influences maternal and infant HRV cannot be supported, but there is a trend that maternal PA might increase fetal HRV. Therefore, we recommend that further studies on the influence of maternal PA on HRV should be performed. References Clapp JF. DEVELOPMENT OF ADVANCED POSITION MEASUREMENT SYSTEM FOR SPORTS TEAMS

SHIMPEI, A.1, TAKESHI, T.1, HIDEYUKI, B.1, NORIO, G.2, SHUNICHI, T.3

Hitachi,Ltd. *1, Hitachi,Ltd. *2, University of Doshisha *3

Introduction Sports analytics using advanced sensors is introduced actively into competitive sports. In competitive sports' team, formation assessment of the team is essential in order to achieve advantageous situations in games. However, the accuracies of conventional position measurement technologies such as GPS and video analytics are insufficient. Therefore, the aim of this study is to develop a technology that has better position measurement accuracy. Methods To investigate the necessary accuracy for formation assessment of the team, we conducted interviews with experts in professional teams. Followings are the requirements set by the experts. (1) Accuracy of players' position measurement < 10 cm error (2) Accuracy of personal identification > 90% We considered the new position measurement method combining with Laser Radar and acceleration sensor. The advantage of using Laser Radar is that the error in position measurement is less than 10 cm. However, it is not able to identify individuals. Another method for personal identification is necessary. Then, we found out that players' speed measured by the Laser Radar is associated with energy consumption measured by wearable acceleration sensor. The proposed method measures the trajectories of identified individuals by performing the matching based on similarities. Evaluation We performed an experiment to assess the accuracy of the proposed method. Specifically, we calculated the matching rate between the personal trajectories identified by the proposed method and the actual personal trajectories that were assigned visually. The experiment was carried out on a 3-on-3 passing game called 'Ballschule' that has movements that common with major team sports. We measured a total of 130 trajectories in these games. Results The proposed system accurately identified the individuals in 119/130 trajectories, and the accuracy of personal identification is 91.5%. The accuracy of more than 90% was achieved while keeping the error in players' position measurements of less than 10 cm. Conclusion This study shows that a new method to measure personal trajectories with high accuracy by combining with Laser Radar System and acceleration sensors. EVALUATION OF A NOVEL NONINVASIVE BLOOD HEMOGLOBIN MONITOR DEVELOPED FOR ATHLETES

MOUGIOS, V., PANCH, A., TSALIS, G., OLSEN, G., CHIBA, M.

Aristotle University of Thessaloniki

Introduction Ember is a new product, developed at Cercacor for the endurance athlete, which measures the blood hemoglobin concentration, [Hgb], noninvasively. The technology, based on Pulse CO-Oximetry, is meant to help athletes monitor their performance by measuring and tracking the impact training has on [Hgb]. Ember uses a sensor placed at a fingertip. The sensor is connected to a device which processes the sensor's signal and produces a reading that is calibrated to the hemoglobin concentration in venous blood. The aim of this study was to evaluate Ember in terms of accuracy and reproducibility of its readings. Methods The trend accuracy of Ember technology, defined as its ability to detect changes in [Hgb] when compared to changes detected by an invasive method, was tested in a "hemodilution" study involving 266 subjects. During the study, 450-500 mL of blood were drawn and rapidly replaced with isotonic intravenous fluid. The [Hgb] was measured during the hemodilution process by an ABL Radiometer blood gas analyzer and, simultaneously, by sensors using Ember technology. To test the reproducibility of Ember, we performed duplicate successive measures in 119 athletes of both genders and a wide age range. Results The trend accuracy of Ember technology was found to be within 0.7 g/dL at one standard deviation. This finding takes into consideration errors that could be introduced from placement of the sensor and, therefore, should be indicative of real-world performance. The reproducibility of single measures was high, with intraclass correlation coefficients (ICC) of about 0.83, while the reproducibility of average measures was excellent, with ICC of about 0.91. The median difference between duplicate measures was 0.5 g/dL. Discussion Ember displays good trend accuracy in measuring [Hgb] noninvasively when compared to an invasive reference. In addition, Ember produces hemoglobin readings of high reproducibility, which becomes excellent when duplicate measures are taken and averaged. These findings suggest that the Ember system is suitable as a tool for the study of the acute and chronic effects of exercise on [Hgb]. The findings encourage further research to understand the potential use of Ember in evaluating athletic performance. Contact Vassilis Mougios, mougios@auth.gr

COMPARING THE PRACTICES OF USA ICE HOCKEY AGAINST A GLOBAL MODEL FOR INTEGRATED DEVELOPMENT OF MASS AND HIGH PERFORMANCE SPORT

MARCAURELE, C., SMOLIANOV, P., SCHOEN, C.

Salem State University

This study was designed to help and improve international ice hockey performance as well as increase domestic hockey participation in the United States. Over 200 sources of literature on sport delivery systems from 28 Australasian, North and South American, Western and Eastern European countries were analyzed to construct a globally applicable model of high performance ice hockey integrated with mass participation, comprised of the following seven elements distributed across three levels: Micro level (operations, processes, and methodologies for development of individual athletes): 1. Talent search and development, 2. Advanced athlete support. Meso level (infrastructures, personnel, and services enabling sport programs): 3. Training centers, 4. Competition systems, 5. Intellectual services. Macro level (socio-economic, cultural, legislative, and organizational): 6. Partnerships with supporting agencies, 7. Balanced and integrated funding and structures of mass and elite sport. The above model was used to design a questionnaire of 54 statements reflecting desired practices. The 54 statements were validated by 12 international experts, including executives from sport governing bodies and academics who published on high performance and sport development. The survey samples of 2,000 hockey professionals' email addresses were collected from various sources, including web pages of USA Hockey, regional and state hockey associations, college and university athletics as well as high school and club hockey teams. Completed online questionnaires were returned by 111 coaches from all key

regions of the country for a response rate of 5.5%. Additionally, 15 regional administrators were interviewed to suggest possible hockey system improvements. The study identifies best management practices as part of the American Development Model used by USA Hockey and provides suggestions for improvement, particularly consistent national qualification, education and award systems for athletes and coaches across all participation levels, further education of volunteers, and provision of greater number of competent coaches per participant at the youth level.

THE EVOLUTION OF SPORT CLUBS IN CATALONIA <2009-2015>

ROCHER, M.1, DÍAZ, N.1, ANDRÉS, A.1, CAMPS, A.1, PUIG, N.1

1: Observatori Català de l'Esport (OCE)

Introduction The Catalan Sports Observatory (OCE) is an organism dependent of the Government of Catalonia- INEFC that studies the evolution of the sport phenomenon in Catalonia. The Observatory has developed a study of the situation of sport clubs in Catalonia, which studies the situation of sport in 2015 and its evolution since 2009. Its objective is to show the current situation of Catalan sport clubs and associations and see what changes they have undergone since 2009. **Methods Sample:** 474 sport clubs and associations of Catalonia (5.7% of the total) (N=8.285). The level of accuracy is 95% and a margin of error of $\pm 4.35\%$. Online survey of 26 closed questions and a final open question. **Results** More than half of the Catalan clubs (68,7%) have up to 100 members and are part of towns of more than 20.000 inhabitants (72,3%), and for this reason the small clubs located in the Barcelona metropolitan area prevail (58,1%), this tendencies have increased compared to 2009. Councils (95.5%) and regional government (Consell Català de l'Esport), (62.3%) are the main stakeholders' clubs. 98,39% of the Catalan clubs offer a federate sport being competition sport an important part of their offer and the participation in international competitions has had a 12.4% increase since 2009. Aside from federate sport the clubs now offer a variety of sport activities. The activities for specific groups have increased considerably, especially those directed to children up to 6 years of age (a 29.4% increase since 2009) and activities for handicapped people (a 15.4% increase). Finally in relation to the staff of the clubs there is a big difference between paid staff and volunteer staff. Paid staff are in the clubs with more than 1000 members (77%) while volunteer staff have an important paper in clubs with less than 1000 members (71.8%). **Comparing the tendency,** we can see significant changes, in 2009 the volunteers were a minor (38.3%) in clubs with less than 1000 members. **Discussion** The relationship of Catalan clubs with their stakeholders has increased because of the importance that this represents for the development of sports practice. The stakeholders help financially or through the cession of sport facilities for the practice of sport. The strong relationship with the federations since 2009 is a trend that is maintained over the years. No changes are observed in the size (members) of Catalan clubs where 95% of these have up to 1,000 members, so the big clubs are still a minority. There has been a significant increase of sports activities for specific groups and the participation in international competitions. **References** Observatori Català de l'Esport; (Eds) (2015) Informe de l'estudi sobre la situació dels clubs esportius a Catalunya. A STUDY ON PROCESS OF CAREER FORMATION IN JAPANESE FEMALE FOOTBALL PLAYERS

UEMUKAI, K.1, INABA, K.2, IIDA, Y.3

1: Musashi University/Tokyo, Japan/ 2: Seikei University/Tokyo, Japan/ 3: Senshu University/Tokyo, Japan/

Introduction There are some studies related to the career development of athletes in Japan had been carried out so far, however they are mostly based on sport psychology and sport policy. In the field of sport sociology, accumulated studies include "socialization to/by sports", sociological study of school club activities, history of career development focusing on difficulties that athletes face and a discussion on their second career among others. Iida(2012) had conducted quantitative as well as qualitative researches of J-League academy players and their parents by focusing on their career formation and process. On the other hand, there are not many teams for girls and it is not easy for them to continue playing football after junior high school. Furthermore, there is no option available to become a professional even after they continue their football career up to a high level, so the options to play at a university compared to the male players are not enough either. That means female players have to build their career among unclear and limited options. What kind of impact does this environmental difference bring to the career development process? This study develops from the questions and interests in Iida's discussion and expands the subject to female football players to find out its characteristics and challenges in comparison with male football players in Japan. **Methods** The content of questionnaire includes: when and why they started to play football; factors to carry on this career; background details and reasons for joining their current team; what they think of their current environment that they play football in; what they think of their future as footballers; and any factors or persons that affected their decisions when their environment changed. 212 University female football players provided valid data. **Results and Discussion** Almost subjects in this study started to play when they were in a lower grade of elementary school and belonged to local club rather than junior high-school team. This result reflects an issue of girls' football in Japan, which lacks the system of "club activities" at school after they move on to a junior high school. Furthermore, one of the reasons to choose their high school is because that was a school with a strong football team but only less than 20% of the students talked to their coach about their choice of school and a great number of them consulted their mothers. Similar responses applied to their consultation on their future careers. Considering some preceding studies of male football players, similar research showed that coaches made more of a presence in consulting on the contrary, so it seems to be necessary to further examine the background of this result. **References** Iida Y. (2012) Study on the process of career decision-making of youth players in J-League Academy. Bulletin of Health and Sports Sciences Institute Senshu University, 36, 17-28. THE ANALYSIS OF SPORT CLUBS IN CATALONIA FROM A GENDER PERSPECTIVE

DÍAZ, N.1, ROCHER, M.1, ANDRÉS, A.1, CAMPS, A.1, PUIG, N.1

1: Observatori Català de l'Esport (OCE)

Introduction The Catalan Sports Observatory (OCE) has developed, in the last few months, a study that aims to describe the current situation of sport clubs and associations in Catalonia (territory with the highest number of clubs in Spain) and analyze the evolution from 2009 to 2015 from a gender perspective. The specific objectives were to analyze the possible differential situation existing between both sexes, from two points of view: from the partners and associates and from the structure of human resources. **Methods Sample:** 474 sport clubs and associations of Catalonia, (5.7% of the total) (N=8.285). The level of accuracy is 95% and a margin of error of $\pm 4.35\%$. The data were collected through an online survey of 26 closed questions and a final open question. **Results** The people associated to a club define its characteristics and the activities it offers. In Catalonia, the majority of people associated to a club, in whatever measure, are men. This tendency has been constant since the study done in 2009 even though we have found minor variations. The most significant data is the

10.7% increase in women membership in clubs with 101 to 300 members. When we pay attention to the sport federate licenses in 2015, independently from the size of the club, the majority belong to men (70.5% men, 29.5% women). The figures in 2009 were very similar. If we begin to analyze the structure of the clubs, starting by the boards of directors, we find that men occupy most of the positions. A clear example can be found in presidential positions, where only 11.3% are women. The figures between 2009 and 2015 show the same tendency, the variations are more visible in treasury areas where the presence of women has increased 6% with a total of 31%. Where we find more women is in secretarial positions where there is a total of 32.9% (3.9% more than in 2009). In relation to the staff of the clubs, once again we find that the proportion of men is higher than that of women. Comparing the results of different years we can see that all the figures have increased for women except in management positions, the most important increase being in the area of technical direction. Discussion In this study we can see that men predominate in the 4 indicators studied, being presidential positions where there is a greater gender difference (88.7% men versus 11.3% women). The tendencies remain since 2009 but we can observe that in some areas the presence of women is gradually increasing. The most remarkable increase in all the areas studied is the 12.2% increase in women that are in the area of technical direction of a club. THE DEVELOPMENT OF ELITE SWIMMING IN THE PEOPLE'S REPUBLIC OF CHINA – FROM THE PERSPECTIVE OF POLICY TRANSFER

TIEN-CHIN, T.

National Taiwan Normal University

China's longing to win for Olympic Glory has driven it to put a great deal of effort into the field for the past three decades, including its enormous investment of both human and material resources. China's investment reached a climax in the 2008 Olympic Games in Beijing while earning back only won six medals (1 gold, 3 silver, 2 bronze) in swimming, which has always been the field in which Western countries are predominant (Olympic, 2014). Nevertheless, at the 2012 Olympic Games in London, the China Olympic swimming team broke its Olympic record with ten medals gained in total (5 gold, 2 silver, 3 bronze). This achievement brought China's swimming to the second place in the world rankings, thus helping China surpass Japan and take the first place in Asia. How China improved its performances in elite sports, especially swimming, is said to be relevant to its policy transfer process from other countries predominant in swimming (Houlihan, Tan & Green, 2010; Hsu, 2014). This research aims at elaborating the idea of policy transfer, through which we could analyze the development of the development of elite swimming in China. Adapted from Dolowitz & Marsh (2000), our theoretical framework of policy transfer includes seven key questions: Why policy transfer happens, who are the key actors involved in policy transfer? What is transferred? From where are lessons drawn? What are different degrees of transfer? What restricts or facilitates the process? How is the whole process of policy transfer related to the result of either success or failure? To answer these questions, this research collects official and semi-official documents of China, and further interviews relevant officials, coaches, athletes, sport scientists and scholars. Qualitative content analysis and depth interview are conducted as the approach to data collection, through which we further analyze the development of elite swimming in China. Aspects mainly touched upon are the reasons why, who, effects of policy transfer, and possible conflicts within the process, with which this research hopes to provide the government with substantial suggestions for the development of elite swimming or future sports policy in Taiwan or elsewhere.

THE EFFECT OF TWO DIFFERENT WEIGHT LOSSES ONTO ANAEROBIC POWER VARIABLES OF FREE STYLE WRESTLES DURING WINGATE'S PROTOCOL

YASERIFAR, M.

university of Mazandaran

Introduction Wrestling is an Olympic sports that has done by weight classes (Kaynar and Dasdag, 2011). The topic of weight management is a challenge for athletics, coaches and researchers. Matches planning is created a situation that athlete has to reduce his weight in a short time. It may be effected on muscular function of athletes. A wrestler needs to a high level of physical fitness and muscular power during the competition, the power in the wrestling is related to speed and burst activity in the muscles that lead to success (Vardar et al., 2007). Nevertheless, knowing how much of losing weight influences the wrestlers' power is not clear. Therefore the aim of this study was to investigate the effect of two different weight losses onto changes of anaerobic power variables of free style wrestles during Wingate's protocol. Methodology Twenty seven free style wrestlers (mean \pm SD; age 20.55 ± 2.09 years; mass 69.91 ± 7.70 kg, height 170 ± 0.06 cm) volunteered to participate in this study. The variables of anaerobic power (mean power and pick power) and fatigue index were recorded during leg Wingate protocol (pretest). Then subjects were randomly divided into one control group and tow experience groups (E1 and E2). E1 reduce 2-3% and E2 reduce 3-4% of their body weight by using of exercising in a rubber/plastic warm-up suit and foot restriction (Webster et al., 1990) during a week. At the end, they perform the protocol after weight loss (post-test). A Kruskal-Wallis test was applied to analyze the data in groups, Wilcoxon statistic method was applied to analyze the inner changes of the groups ($p < 0.05$). Results There were no significant difference in the anaerobic power parameters (mean power and pick power) and fatigue index between and inner groups. Discussion Considering there were not any difference in the anaerobic power parameters, it seems that weight loss on these ranges of body weight by rubber/plastic warm-up suit and foot restriction during a week has not effect on anaerobic power parameters. However, there are some differences between our results and previous studies. It has been reported that 4.6 % of weight loss (3.3 KG) during 36 hours reduced anaerobic power (Webster et al., 1990). Maybe, the reason of this antithesis relates to duration of weight loss. It seems that losing weight during a week has not effect on anaerobic parameters. Considering the results of this and other studies, it is suggested that wrestlers do weight loss on longer period if they want to prevent the reduction of anaerobic parameters. PRE-PARTICIPATION SCREENING EXAMINATION IN CHILDREN AND ADOLESCENTS

WIPPERMANN, F., SALLER, S., GREIL, S., SCHULZ, T., OBERHOFFER, R.

Technische Universität München

Introduction Physical activity undoubtedly has a beneficial effect on development and prevention of cardiovascular diseases in children and adolescents. Intensive activity can, however, also de-mask previously undetected underlying cardiovascular disease, triggering cardiorespiratory events as well as sudden cardiac death. Therefore, a pre-participation examination is usually recommended in young athletes, taking into account pre-existing risk factors and diseases as well as type of sport. There is no general consensus how this screening examination should be performed and, in consequence, medical guidelines and recommendations differ between societies and countries. European societies currently recommend a pre-participation screening examination which includes medical history, family history, sports history, physical examination and standard ECG. Further diagnostic procedures follow in case of any significant finding. **Methods** The current study retrospectively analyses the results of pre-participation screening examinations performed within two years at the Institute of Preventive Pediatrics, Technical University of Munich, following the above mentioned recommendations. In 90%, echocardiography and spiroergometry were added to further understand their role in detecting pre-existing pathological conditions. Results 242 pre-participation examinations were performed in 22 female and 220 male athletes [mean age 14.73 yrs]. Athletes competitively participated in football, triathlon, ice hockey, field hockey, or swimming. Results frequently showed signs of physiological adaptation to intensive physical activity such as sinus bradycardia or ectopic atrial rhythm, but also findings which required follow-up and further investigation: In 98 athletes (40,5%), echocardiography showed signs of athlete's heart or other structural findings. In one case (male, 16 yrs) myocardial morphology was compatible with non-compaction cardiomyopathy and cardiac magnetic resonance imaging was recommended. Due to the potential impact on his career as a football player, the patient has been lost of follow-up despite a detailed discussion about potential risks. **Conclusion** The study shows, that in children and adolescents basic pre-participation screening examinations including medical history, family history, sports history, physical examination and standard ECG provide important information about potential risks and apparent contraindications to participate in sports. Some findings which may indicate significant pre-existing disease could, however, only be found when other examinations such as echocardiography and spiroergometry were added. Whether these investigations should complement the routine pre-participation examinations requires further investigation.

INTERVAL-TRAINING AND APPETITE REGULATION IN PATIENTS WITH TYPE 2 DIABETES

MÜLLER, I.A.1, SOLOMON, T.P.2, KARSTOFF, K.1

1: Rigshospitalet, University of Copenhagen, Denmark, 2: University of Birmingham, Birmingham, UK

Introduction: Weight loss is recommended for overweight/obese subjects with type 2 diabetes (T2D), and strategies that induce and sustain a weight loss are warranted. We have recently shown that 4 months of interval training induces weight loss to a greater extent than continuous training. The reason for this is unclear but may be dependent on differential appetite regulation following single exercise sessions. Therefore, the aim of this study was to investigate if an acute bout of interval-walking (IW) results in differential changes in energy-intake and appetite regulation compared to an acute bout of continuous walking (CW) in subjects with T2D. **Methods:** Fourteen subjects with T2D were included in the study (2530 y). Subjects underwent three trials in a randomised order. Trials were separated by one week and were identical except the following one-hour interventions: 1) Control (CON); 2) Continuous walking (CW); 3) Interval walking (IW – repeated cycles of 3 min of slow and 3 min of fast walking). Interventions were controlled using indirect calorimetry with the aim to match CW and IW for oxygen consumption rates. Following the intervention, subjects consumed a standard liquid mixed meal tolerance test (MMTT - 300 kCal; 15E% protein, 30E% fat, 55E% carbohydrate) with repeated satiety questionnaires (Visual analogue scales) every hour during the following three hours. Three hours after starting the MMTT, subjects were given an ad-libitum meal consisting of either meatballs with curry-sauce and rice or minced meat with mashed potatoes. Following the MMTT, subjects kept diet records until the end of the following day. Preliminary results (n=5): Oxygen consumption was well-matched between CW ($1648 \pm 253 \text{ mlO}_2/\text{min}$) and IW ($1643 \pm 256 \text{ mlO}_2/\text{min}$, $P>0.05$). Ad-libitum meal energy intake did not differ significantly between interventions, but was numerically higher in CON ($798 \pm 69 \text{ kCal}$) and CW ($763 \pm 32 \text{ kCal}$) than in IW ($683 \pm 55 \text{ kCal}$, $P>0.05$ for all comparisons). Moreover, hunger sensation during the MMTT did not differ significantly between interventions, but was numerically higher in CON ($47 \pm 14 \text{ a.u.}$) and CW ($49 \pm 8 \text{ a.u.}$) compared to IW ($36 \pm 10 \text{ a.u.}$, $p>0.05$ for all comparisons). Based on diet records, free-living energy intake did not differ between interventions, neither at the intervention day nor at the day after. **Conclusions:** While the study is ongoing and the current analyses are under-powered, preliminary data indicate that interval type exercise might acutely suppress appetite and energy intake compared to continuous type exercise and no exercise.

CHANGE OF THE FLUID COMPONENT IN CALF AND ATHLETIC PERFORMANCE IN A MENSTRUAL CYCLE

SAWAI, A., TOCHIGI, Y., WARASHINA, Y., SHIRAKI, H., WATANABE, K.

University of Tsukuba

Introduction A discomfort feel of edema during a menstrual cycle are reported in 10% of Japanese female athletes. The purpose of this study was to evaluate fluid change in calf in a menstrual cycle using Magnetic Resonance Imaging (MRI) quantitatively and investigate its association with athletic performance. **Methods** 14 young healthy women (23.6 ± 0.3 years) with regular menstrual cycle participated in this study. Body composition, serum Estradiol (E2), Progesterone (P4) and Aldosterone (Ald) were measured at 7:00- 8:00 in AM, and the athletic performance were estimated by static balance test, jump test, side steps, muscle strength of plantar flexion/dorsiflexion in ankle at 14:00-16:00 in PM. MRI in lower leg was performed both in AM and in PM. All measurements were performed every phase of a menstrual cycle: Menstrual (MP), Follicular (FP), Ovulatory (OP), Early Luteal (ELP) and Late Luteal (LLP). Results E2 and P4 were the highest in the ELP and Ald was the highest in the LLP. Although there were no changes in body composition during the menstrual cycle, the fluid in PM and the change of fluid between AM and PM increased significantly in the MP. Static balance test increased significantly in the MP and side step decreased significantly in the MP. Also, there was a negative correlation between side step and the fluid in calf from AM to PM. Discussion Fluid in calf marked the most in PM and the difference between AM and PM in the MP. It has been reported P4 might play an important roles in fluid distribution, especially in fluid retention in the body (Olson et al. 1996) as well as activate the Renin-Angiotensin-Aldosterone System (Stachenfeld, 2004) (Stachenfeld, 2008). The highest level in P4 and E2 in the ELP and Ald in LLP suggests that the hormones may act differently to the fluid balance. Side step decreased significantly in the MP. Lebrun et al. reported that the performance ability remarks the worst in the 2-3 days from the menstruation (Lebrun, 1993), which may support our result. Also, there was a negative correlation between the side step and the difference in the fluid from AM to PM in the MP, which the significant increase of fluid in calf in the MP and maybe the one of the factor that decreases the side step. **References** 1. SARCOPENIA AND HIP STRUCTURE ANALYSIS VARIABLES IN A GROUP OF LEBANESE POSTMENOPAUSAL WOMEN

NASR, R., BERRO, A.J., ALWAN, A., BADDOURA, R., EL HAGE, R.

Balamand university

Introduction: Muscle mass decreases with age, leading to "sarcopenia" or low muscle mass, in elderly people [1]. The aim of this study was to compare geometric indices of hip bone strength in postmenopausal women with sarcopenia and postmenopausal women with normal skeletal muscle mass index. Methods: This study included 8 postmenopausal women (aged between 65 and 84 years) with sarcopenia and 60 age-matched controls (with normal skeletal muscle mass index). Body composition and bone mineral density (BMD) were assessed by dual-energy X-ray absorptiometry (DXA). We used the skeletal muscle mass index (appendicular skeletal mass (ASM)/height²) to define sarcopenia as previously described [1]. A skeletal muscle mass index (SMI) < 5.5 kg/m² was defined as the cut point for sarcopenia [1]. To evaluate hip bone geometry, DXA scans were analyzed at the femoral neck (FN), the intertrochanteric region (IT), and the femoral shaft (FS) by the Hip Structure Analysis (HSA) program. Cross sectional area (CSA), an index of axial compression strength and section modulus (Z), an index of bending strength were measured from bone mass profiles. Results: Weight, lean mass, BMI, FN CSA, FN Z, IT CSA, IT Z, FS CSA and FS Z were significantly higher in women with normal SMI compared to women with sarcopenia. In the whole population, SMI was positively correlated to CSA and Z of the intertrochanteric and the femoral shaft regions. Conclusion: This study suggests that sarcopenia negatively affects hip bone strength indices in postmenopausal women. References: [1] Baumgartner RN, Koehler KM, Gallagher D, Romero L, Heymsfield SB, Ross RR, Garry PJ, Lindeman RD. Epidemiology of sarcopenia among the elderly in New Mexico. SKELETAL MUSCLE MASS INDEX AND BONE MINERAL DENSITY IN A GROUP OF LEBANESE POSTMENOPAUSAL WOMEN

ALWAN, A., BERRO, A.J., NASR, R., BADDOURA, R., EL HAGE, R.

university of balamand

Introduction: Muscle mass decreases with age, leading to "sarcopenia" or low muscle mass, in elderly people [1]. The aim of this study was to compare bone mineral density in postmenopausal women with sarcopenia and postmenopausal women with normal skeletal muscle mass index. Methods: This study included 10 postmenopausal women (aged between 65 and 84 years) with sarcopenia and 73 age-matched controls (with normal skeletal muscle mass index). Body composition and bone mineral density (BMD) were assessed by dual-energy X-ray absorptiometry (DXA). We used the skeletal muscle mass index (appendicular skeletal mass (ASM)/height²) to define sarcopenia as previously described [1]. A skeletal muscle mass index (SMI) < 5.5 kg/m² was defined as the cut point for sarcopenia [1]. Bone mineral content (BMC) and BMD were measured at whole body (WB), lumbar spine (L1-L4), total hip (TH) and femoral neck (FN). Results: Weight, lean mass, SMI, body mass index (BMI), WB BMC and TH BMD were significantly higher in women with normal SMI compared to women with sarcopenia. WB BMD, L1-L4 BMD and FN BMD values were not significantly different between the two groups. In the whole population, SMI was positively correlated to WB BMC, TH BMD and FN BMD. Conclusion: This study suggests that SMI is a positive determinant of whole body bone mineral content and hip bone mineral density in postmenopausal women. THE EFFECT OF ELEVATION ON INTRAMUSCULAR TISSUE TEMPERATURE

GILLETTE, C., MERRICK, M.

University of Wisconsin-La Crosse, The Ohio State University

Introduction Ice (I), compression (C), and elevation (E), or ICE, is a universally accepted treatment for acute musculoskeletal injuries; however, it has received recent scrutiny regarding its clinical effectiveness (van den Bekerom et al., 2012), with the component of elevation having the least literature regarding its effectiveness. The aim of this study is to examine tissue cooling at several depths with ice, compression, and elevation. Methods Fifteen healthy subjects completed eight conditions including: No treatment, ice only (I), compression only (C), elevation only (E), ice and compression (IC), ice and elevation (IE), compression and elevation (CE), or ice, compression and elevation (ICE). All conditions were tested on each subject with a minimum of 48 hours between each condition. Intramuscular temperatures were recorded every 30 seconds during a 1 minute pre-application period, 30 minute treatment period, and 20 minute post-application period. Results No treatment (control), C, E, and CE showed significant differences with any treatment that included ice (I, IC, IE, ICE). No significant difference was seen between IC and ICE. Finally, ice alone was significantly different with everything except IE. Skin and intramuscular temperatures increased with C, E, and CE, yet only the changes in skin temperature were significant (.001 and .001, respectively). Discussion From these results elevation does not appear to have an effect on tissue temperature that would indicate it is beneficial for reducing secondary injury. For both measurement locations and treatments, we observed changes similar to those reported in the literature (Merrick et al., 1993; Jutte et al., 2001; Dykstra et al., 2009; Merrick et al., 2003). A limitation of this study was that temperature changes were measured in the gastrocnemius in individuals who were not injured nor active. Different results may have occurred if the individuals had been exercising or after acute injury. Evidence for the effects of elevation on musculoskeletal injury in the low limb are lacking (van den Bekerom et al., 2012) and its use remains highly dependent on the expert opinion that elevation decreases hydrostatic pressure in the vasculature and decreases resistance to venous and lymphatic flow (Bleakley et al., 2010). Further studies need to be completed to conclude the effects and potential benefits of elevation. THE EFFECT OF HIGH- AND LOW-INTENSITY INSPIRATORY MUSCLE TRAINING ON THE PHYSIOLOGICAL RESPONSE TO EXERCISE IN CROSS-COUNTRY SKIERS

KLUSIEWICZ, A.1, STARCZEWSKI, M.1, ZUBIK, L.2, DLUGOLECKA, B.2

1 Institute of Sport-National Research Institute, Warsaw, Poland, 2 University of Physical Education in Warsaw, Faculty of Physical Education and Sport in Biala Podlaska, Poland

Aim The aim of the study was to evaluate the impact of isolated respiratory muscle training (RMT) on the work capacity and changes in selected spirometric parameters in trained cross-country skiers. **Methods** The study involved 4 female and 12 male skiers. A cross-over model was used: each subject belonged both to the group that completed 7 weeks of RMT training (the RMT group) and the one that completed 7 weeks of simulated RMT (the placebo group). Half of the subjects started by performing RMT and the other half by performing simulated RMT. Both RMT programmes consisted in performing 30 inspiratory manoeuvres twice a day, 6 days a week, using the heavy resistance model of POWERbreath®. In the RMT group, resistance was gradually increased in subsequent weeks, whereas in the placebo group, resistance was set to 29 cmH2O (level 0) in the first week, and in the next six weeks it was set to a constant value of 53 cmH2O (level 1). All of the subjects underwent spirometric measurements and a stress test in the following stages of the study: before the experiment, after the change in RMT, and after the experiment. The spirometric measurements were used to determine i.a. maximal inspiratory pressure (P_{max}). The stress test was conducted on a ski ergometer, with a gradual increase in intensity, and was continued until exhaustion. **Results** A significant increase in P_{max} and in the work performed in the stress test was observed in both the RMT and placebo group for male cross-country skiers, but only in the RMT group for female skiers. No significant differences in P_{max} or work were observed between the RMT and placebo group, regardless of the gender of the skiers. **Conclusion** We found that completing a 7-week RMT programme did not cause an increase in the work capacity of trained skiers. The effects of RMT on improving P_{max}, which is indicative of the strength of the inspiratory muscles, depend on the magnitude of inspiratory resistance. The principle of gradually increasing inspiratory resistance according to a given person's progress in training should be followed in implementing RMT. The study also showed that RMT did not have a considerable impact on breathing efficiency in maximal effort. PACING PROFILES BETWEEN DIFFERENT LEVELS OF SUB-3H PERFORMERS AT THE CLASSIC MARATHON COURSE

XERGIA, S., PATRAS, K.

European University of Cyprus,

Introduction The classic Athens marathon course is characterized by special difficulty, mainly due to a progressively ascending segment that extends between the 18th and the 31th km. This prolonged ascending course may add further challenges in the selection of a proper pacing profile (1, 2, 3). Therefore the aim of the study was to describe pacing profiles of sub-3h performers in the classic Athens marathon course. **Methods** Finishing and split times for the 0-5, 5-10, 10-21.1, 21.1-30 and 30-42.2 km segments were collated for 811 men across eight consecutive competitions (2007-2014) and the mean speeds for each segment were calculated. Athletes were categorized in five groups according to the 5th, 25th, 50th and 75th percentile of all sub-3h finishing times. Two-way analysis of variance with Scheffe post-hoc tests was conducted to compare mean segment speeds between groups and to identify changes between successive race segments for each group. Level of significance was set at $\alpha=.05$. Results Group 1 athletes were faster than all other groups in all intermediate segments (all $p<.001$), Group 2 athletes were faster than all other inferior groups in all intermediate segments (all $p<.001$) and Group 3 athletes were faster than all other inferior groups in all intermediate segments (all $p<.002$). Group 1 athletes demonstrated no significant change in speed between consecutive pairs of segments. Groups 2 and 3 maintained speed between the 0-5 and 5-10 and between the 5-10 and 10-21.1 km segments, whilst Groups 4 and 5 maintained speed between the 0-5 and 5-10 km segments. **Discussion** The results of the present study confirm the differences in pacing strategies between successful and less successful marathoners (1, 2, 3). Top finishers were able to maintain their average speed between consecutive segments despite a progressively ascending segment at about midway, whilst intermediate and bottom sub-3h performers showed significant speed reductions during the progressively ascending segment or even sooner. Maintaining a consistent marathon pace results in an effective race profile for best performance (1, 2). References 1. Renfree A, St Clair Gibson A. EFFECTS OF SIX WEEKS OF DIFFERENT HIGH INTENSITY INTERVAL VERSUS MODERATE CONTINUOUS TRAINING ON AEROBIC AND ANAEROBIC PERFORMANCE

CAVAR, M.1, MARSIC, T.1, CORLUKA, M.1, CERKEZ, I.1, CULJAK, Z.1, MÜLLER, A.2, TSCHAKERT, G.2, HOFMANN, P.2

1: Faculty of Science and Education, University of Mostar (Bosnia and Herzegovina) 2: Institut Sports Sci., Univ. Graz (Graz, Austria)

Introduction Effects of diverse intensity training including high intensity interval training (HIT) on aerobic capacity are still underexplored. Most HIT studies were single comparisons to continuous moderate intensity exercise in the lab (Tschakert et al. 2015, Gibala et al. 2006). Aim was to explore effects of 3 different training programs on aerobic and anaerobic capacity as well as time to exhaustion (TTE). Methods 44 male trained subjects assigned in 3 groups according to Beep test (Leger et al. 1988) results, exercised at different % of the maximal shuttle run speed (MASS) and work/rest schedule 2x weekly for 6 weeks. 3 ranges of %MASS were individually defined and intensities progressed weekly. Beep test and 300 yard test were performed to determine aerobic and anaerobic performance. Programs: A) 10s work - 10s rest intervals shuttle run at 115% - 120% of MASS (passive rest, N=16), repetitions in each set (3 sets with 2 min of rest between) were set to be 70% of TTE in cited interval regime and were approx. 15; B) 3 x 4 minutes intervals at 90 to 95% MASS (2-3 minutes passive rest) (N=17). Intensities were matched to demonstrate TTE at approx. 5.5 min duration of work; C) continuous shuttle running (CSR) at 70%

of MASS (35 minutes of CSR, N=11). Results 3x2 ANOVA showed sign. group time effects for Beep and 300 yard tests. Post hoc Fisher LSD test evidenced no sign. post-test changes for C in both tests. Intervals groups A, B advanced in both tests, and B progressed sign. greater than A in Beep (12.94 vs. 7.63 shuttles) and A in 300 yard (2.43s vs. 1.03s). Sign. post-test improvements of TTE were evidenced for both interval programs in TTE working regime at 5% higher intensity than in pre-tests, where A advanced more (but not sign) in TTE than B (28.7% vs. 7.6%). CSR tests applied showed sign. negative changes in the same TTE. Discussion Some specificity of the applied training was found as A was more effective improving anaerobic performance than B, while the opposite was found for aerobic capacity. CSR yielded no sign. changes, although performing the highest volume. Transformation of TTE around MASS seems to be more pronounced in interval schedules than in continuous ones and for the best results in each TTE regime, probably specific interval training strategies should be applied. CHRONIC AND ACUTE HORMONAL RESPONSES AFTER TWO TYPES OF ENDURANCE TRAINING

ŠČIBRÁNY, A., KAMPMILLER, T., SEDLIAK, M., VANDERKA, M.

Comenius University

Chronic and acute hormonal responses after the strength training are well established but less is known on the effects of endurance training. This study assessed the hormonal responses of blood testosterone (T), cortisol (C) and growth hormone (GH) concentrations after 8-weeks endurance training. Running performance was tested by the Cooper test. Thirty young males were divided into two groups: interval running (INT) ($n = 14$) and distance running (DIST) ($n = 16$) group. Training in INT consisted of 50 repetitions of 10-s intervals with 10-s resting period, length of section was either 44 m (Cooper test ≤ 2900 m) or 50 m (Cooper test > 2900 m). Three sections were added every week. Training in DIST started with 30-minute running (70 % of the mean velocity during the Cooper test), duration increased by 2-minutes per week. Training was applied 3 times per week. Morning basal serum hormone concentrations were measured before (PRE) and after (POST1) the experiment. Acute hormonal responses were tested after the training period only, 20 minutes after the Cooper test (POST2). We monitored also changes in distance covered in Cooper test. In INT, significant decreases of C concentrations from PRE to POST1 ($p < 0.05$, $d = 0.82$) and from POST1 to POST2 ($p < 0.01$, $d = 0.75$) were found. Testosterone did not change significantly. GH significantly increased from POST1 to POST2 ($p < 0.01$, $d = 2.34$) but no chronic basal changes were observed. In DIST, statistically significant decrease in C from PRE to POST1 ($p < 0.01$, $d = 0.58$) and from POST1 to POST2 ($p < 0.01$, $d = 0.9$) was found. T increased from PRE to POST1 ($p < 0.05$, $d = 0.41$). Growth hormone was significantly higher after 8-weeks ($p < 0.01$, $d = 2.07$) and also after the acute loading ($p < 0.01$, $d = 2.15$). Both groups improved their running performance measured by distance in the Copper test ($p < 0.01$, $d = 0.59$ and $p < 0.05$, $d = 0.34$ in INT and DIST, respectively) with no significant differences between the groups. In conclusions, both types of endurance training induced significant decreases in resting C and similar acute elevations in GH. Differences in the acute T responses may reflect physiological specificity of the two training protocols.

THE EFFECT OF THE PROGRAM FOR DISCOVERING AND FOSTERING KOREA SPORTS TALENTS

YOON, J.R., KIM, H.J., LEE, H.C., JO, J.Y., JO, I.H., CHANG, D.K.

Korea National Sport University

Introduction In general, olympic athletes found their own performance at 8 to 12 years old through various programs. Furthermore, as it has reported that the program for discovering and fostering Korea Sports Talents has an effective influence on enhancement of athletic performance, the importance of the program development for young athletes at the national level has been emphasized. Therefore, the purpose of this study is to evaluate the effect of the program for discovering and fostering Korea Sports Talents by comparing records of the physical performance test(Basketball throw, Sit-up, Half Squat, Standing long jump, 20m Shuttle run, The 50m run, Sidestep, Seated forward flexion) before and after starting the program. Methods The study subjects are 45 elementary school students (Age : 9.95years old ± 1.44 , Height : $143.65\text{cm} \pm 11.84$, Weight : $36.22\text{kg} \pm 11.09$) who have participated in 2015 Sports Talents Training Program. They were classified into a track and field training group (23 students), a swimming training group (12 students) and a gymnastics training group (10 students) and performed individual training (Track and field, Swimming, Gymnastics) twice a week for 3 hours a day for 6months. Results Based on analysis of the basic physical performance test records before and after individual training, (I) those participated in a track and field training program showed a significant improvement in Basketball throw ($t=-5.425$, $p<0.001$), Sit-up ($t=-2.814$, $p=0.01$), Standing long jump ($t=-4.595$, $p<0.001$), 50m run($t=3.688$, $p=0.001$) and 20m Shuttle run($t=-2.494$, $p=0.022$). Those participated in a swimming program showed a significant improvement in Basketball throw($t=-11.238$, $p<0.001$), Sit-up ($t=-2.748$, $p=0.019$). Those participated in a gymnastic training program showed a significant improvement in Seated forward flexion test ($t=-2.712$, $p<0.024$). Discussion Consequently, the track and filed training program for discovering and fostering Korea Sports Talents is effective at improving muscular power, muscular endurance and cardiovascular endurance. The swimming training program is effective at improving muscular power, muscular endurance. The gymnastic program is effective at improving flexibility. Contact jryoon@knsu.ac.kr

PHYSIOLOGY OF A FEMALE JUNIOR WORLD CROSS-COUNTRY CYCLING CHAMPION: FROM YOUTH CATEGORIES TO JUNIOR SUCCESS

FORNASIERO, A., SAVOLDELLI, A., MODENA, R., PELLEGRINI, B., SCHENA, F.

Cerism - University of Verona

Introduction Cross-country bikers require highly developed aerobic and anaerobic systems to sustain performance demands [1]. Although these physiological characteristics, as well as a specific anthropometry, seem to be a prerequisite to compete successfully in adult age, few data are available about the development of these characteristics. This study shows the evolution of a young female cyclist, from youth categories to her success as junior world champion. Methods Every year during the competition period, from 14 to 16 years old, the athlete underwent an anthropometric evaluation, an incremental test and a 30 s Wingate Test. Throughout this period she competed for the national youth team. This has permitted a comparison with same age female bikers performing equal assessments. Results Height and body mass grew from 159.7 cm; 50.1 kg at 14 years old to 161.2 cm; 53.7 kg at 16 yo. VO₂peak was 3.49 L/min at 14 yo, showing the highest relative value: ≈ 70 ml/kg/min. VO₂peak increased at 3.68 L/min at 16 yo. PPO and PRCP increased from 14 to 16 yo, reaching at 16 yo 362 W (6.7 W/kg) and 282 W (5.3 W/kg) respectively. Peak anaerobic power increased from 710 W (14.2 W/kg) to 844 W (15.7 W/kg). Discussion Anthropometric evolution defined a morphological profile advantageous for cross-country performance, where a weight-optimization is required [1]. In each session VO₂peak was the highest seen within the youth national team, +18% (≈ 0.5 L/min) at 14

yo, +10% (\approx 0.35 L/min) at 16 yo, and even exceeded values reported in top level bikers [2]. Also PPO and PRCP were higher than those reported in literature [2]. At 16 yo anaerobic indices showed the highest differences compared with same age national athletes with +19% in Pmax production (W/kg), with values greater than those of 4 female professional cyclists (12°-86° ranking UCI). Conclusion The characteristics required to compete successfully in cross-country cycling [2] are already highly developed in a young female junior world champion. At 16 years old, before entering in junior category, winning a world title, the athlete showed physiological values comparable to top class bikers, producing high power-to-weight ratios and high anaerobic power peaks. EFFECTS OF DIFFERENT PHYSICAL EDUCATION PROGRAMMES ON MOTOR PERFORMANCE, PHYSICAL CAPACITY PERCEPTION AND ACTIVITY ENJOYMENT IN HIGH-SCHOOL STUDENTS

MERNI, F., DI MICHELE, R., CECILIANI, A., TOSELLI, S., SEMPRINI, G.

University of Bologna

INTRODUCTION The aim of the study was to analyze the effects of physical education (PE) activities, characterized by different physical and coordinative demands, on motor performance, self-perception and PE enjoyment. Improvements in PE enjoyment, gross motor skills, coordination, and aerobic performance were hypothesized, respectively, as an effect of team sports, acrobatics, juggling, and fitness-based programs. **METHODS** Four high school classes, including a total of 72 students of both sexes, were involved for a period of two months (two weekly PE hours) into different PE activities: Team Sports (TS), basic Acrobatics (Acr), Juggling (G), and Aerobic Fitness (F). Pre- and post-activity, the following motor tests were performed: Gross Motor Skills (GMS), Standing Long Jump (SLJ), Leger test (LT), Sit & reach (S & R). Furthermore, the Physical Self-Description Questionnaire (PSDQ, Marsh et al. 2010), and the Physical Activity Enjoyment Scale (PACES, Kendzierski and De Carlo, 1991) were administered. **RESULTS** The motor activity enjoyment (PACES score) increased significantly ($p < 0.05$) in boys belonging the TS and G groups, indicating a higher PE enjoyment, while it decreased in girls of the same groups. The perception of one's coordination, strength, flexibility and sports practice (as measured by the PSDQ), generally tended to show no changes or light decreases in all the groups. Only the ACR group showed a slight improvement in perceived strength, and a consistent significant improvement of perceived flexibility. All groups showed improved perception for the health scale of PSDQ. Concerning physical performance tests, G improved especially in the monopodal static item of the GMS test, while Acr and F improved in dynamic items of the GMS test. Acr and G worsened the performance in SLJ. Finally, aerobic performance resulted respectively increased and decreased in F and Acr. **DISCUSSION** The proposed motor activities showed improvements on coordinative motor performance. Regarding the physical performance, two hours per week of PE activities would not seem sufficient to induce specific improvements in high-school students. Moreover, some activities involved a scaled down perception of the students' own abilities. This outcome, together with the improved perception of health status, can represent a motivation for enhanced involvement of students in future physical activities. **REFERENCES** Kendzierski D, De Carlo KL (1991). *J Sports Exercise Psy*, 13, 50-64 Marsh HW, Martin AJ, Jackson SA (2010). *J Sports Exercise Psy*, 32, 438-482

STUDIES ON IMPROVEMENT OF PHYSICAL FITNESS BY MORNING EXERCISE AT ELEMENTARY STUDENTS

TAKEDA, T., OMIYA, T., MASHIYAMA, N., ISHII, Y., YAMAMOTO, K.

Hokusho University

Introduction The decrease of physical strength and ability in children are pointed out in Hokkaido, Japan. We conducted practical research about the physical strength improvement in elementary students in Ebetsu city where our university is located (Takeda et al., 2010~2015). The aim of this study is to examine the effect of the program for improvement of physical fitness for elementary students. **Methods** The subjects were 23 students (10 male, 13 female) in the first grade of elementary school. A "morning exercise" program was made for the subjects and the morning exercise program was carried out 33 times from May to December in 2015. The program was taught by the university students who were aiming to become teachers. The morning exercise program was made for the purpose of physical strength improvement and enjoyment for the students. The new fitness test made by the Japanese Ministry of Education, Culture, Sports, Science and Technology had been carried out before (in May) and after (in December) the program. The exercises performed the new fitness test were the standing broad jump, the power of grip, sit ups, flexibility, sidesteps and a 20m shuttle run (ability of endurance). Statistical differences between the values of before the program (in May) and after the program (in December) were determined by the T test (both sides). Differences with $p < 0.05$ were considered significant. After the program, the questionnaires filled out by the subjects about their feelings for the morning exercise programs were collected. **Results** All values of male's separate exercises had increased in comparison between before and after. However, there were no significant differences between before and after.. Values of standing broad jump, the power of grip, sit ups and flexibility in December (after) were above the National averages. Regarding to the values of female subjects, the power of grip, flexibility, side steps, 20m shuttle run had been increased in comparison between before and after. There was a significant difference between before and after in the 20m shuttle run ($p < 0.05$). Values of standing broad jump, the power of grip, sit ups and flexibility and side steps in December (after) were above the National averages. In the results of questionnaires, 20 subjects answered "they were enjoyed the program very much" and 3 subjects answered "enjoyed the program". **Discussion** From results, the morning exercise program for elementary students in the first grade was effective. In questionnaires after the program, subjects answered that they came to like exercise more than before. The future task is to plan the improvement of the program better. **References** Takeda, T et al. (2015). *Bulletin of Hokusho University School of Lifelong Sport*, 6(1), 13-27. 'ACTIVDISPENS.CH' - BEWEGUNG TROTZ SPORTEINLÄUFER

DIRIWAECHTER, C., WECHSLER, CH.

Schweizerische Arbeitsgruppe für Rehabilitationstraining

Introduction The WHO state that the fourth common cause of death is physical anergia. The increasing akinesia within human society is also observable in children. For many children and young people school sports is their only exercise time. Due to increased use of social media school sports is often the only chance to encourage activity in this age group. Although doctors and sport teachers follow the same aim regarding health promotion, different conditions exist related to school sport dispensation. Aim The aim of this project was to develop a new form of sports dispensation which facilitates the integration of students with a partial dispensation into sports class via customized exercise programmes. Methods By means of two online questionnaires, both structured similarly with respect to questions and main themes, a needs assessment was carried out. The questionnaires were sent by e-mail to 2.600 members of three Swiss medical associations, to doctors of the University Children's hospital of Basel as well as to approximately 4.000 sports teachers of the Swiss organization for sports at school. The addressees were asked to complete the questionnaire within two weeks. The sample size was n=87 (doctors, return rate of 3%) and n=213 (sports teachers, return rate of 5%). A catalogue of 54 exercises was created based on scientific literature in the field of physiotherapy and school sport. These exercises were videotaped and together with a newly created partial dispensation form published on a specific website (www.activdispens.ch). Results Based on the survey feedback, the partial dispensation form should include very precise instructions to differentiate between permitted and prohibited exercises. It should also contain specific information regarding body areas that may be trained versus those that may not. The form should allow fast and precise completion by medical staff, and contain all relevant information for sport teachers. Although teachers' and physicians' demonstrated keen interest in this project following a first pilot phase close collaboration between these groups is not yet established and may be essential for wider acceptance and implementation. Discussion This project may be an important contributing factor to health promotion and illness prevention in the school age population. Broad implementation requires closer collaboration between physicians and teachers.

HOW SHOULD ELITE STUDENTS BALANCE DEMANDS OF COMPETITIVE SPORT AND ACADEMIC CAREERS? A CONCEPT FOR THE EVALUATION OF THE EFFECTS OF GRADUAL EXAMINATIONS IN ELITE SPORT SCHOOLS – THE "ADDITIVES ABITUR"

BORCHERT, T., GERLACH, E., SALLEN, J.

University of Leipzig, University of Potsdam

Introduction Elite student athletes have to manage demands of school education with high-performance athletic training. To reduce the difficulties of balancing those "dual careers" (Borggrefe & Cachay, 2012), the German conference of education introduced a pilot project with the title 'Additives Abitur' at one of the elite sports schools (ESS). The student athletes at this ESS got the opportunity to expand their time at school to obtain a university entrance qualification. Moreover, they can split the final examinations into smaller parts and pass it prematurely to complete a gradual additive examination ("Additives Abitur"; AA). However, there are no empirical findings on this new pilot project. A research project funded by the Federal Institute of Sport Science and the Ministry of Education in the state of Brandenburg will evaluate the effects of this specific institutional solution. Methods The evaluation shall be realized with a combined mixed method longitudinal study. Data from three groups of student athletes will be analyzed: (1) Elite student athletes from the pilot project which use the AA; (2) elite student athletes without using the AA and (3) student athletes who attend regular schools (comparison group). Expected Results The theoretical frame of reference as well as design, sampling and analysis procedures will be discussed. The evaluation can lead to two different scenarios: (1) The evidence of the efficiency concerning the AA and other support offers fails and the educational policies have to think about other support systems in ESS. (2) Conversely, the possibility to empirically prove the effectiveness of the AA would lead to a legitimization to implement the AA Germany-wide. References Borggrefe, C. & Cachay, K. (2012). "Dual Careers": The Structural Coupling of Elite Sport and School Exemplified by the German Verbundsysteme. European Journal for Sport and Society, 9 (1+2), 57-80.

LOAD CHARACTERISTICS OF SOCCER GAMES IN PE CLASSES FROM THE VIEWPOINT OF IMPROVEMENT IN PHYSICAL FITNESS

TSUDA, R.

Kanazawa Medical University

Introduction The majority of studies on ball games in PE classes have focused on techniques and tactics, factors determining skill levels (Griffin et al., 1997). However, under the current Japanese physical education curriculum, it has been necessary to enhance physical fitness even in sport and dance exercises (Mext, 2008). From this point, it is important to examine the load characteristics of ball games in terms of physical fitness. The purpose of this study was to examine the effect of differences in pitch area and player number, ball, and rule of soccer games on characteristics of the games from the viewpoint of improvement in physical fitness. Experiment 1 : Pitch area and player number Methods and Results Twenty male junior high school students participated in the present study. They played four types of games with changing the size of pitch area and player number. (Game A : 30mx20m, 5 players per team ; Game B : 45mx30m, 5players per team ; Game C : 45mx30m, 10 players per team, Game D : 60mx40m, 10 players per team). The number of ball contacts, ratio of appearance time each movement speed, and distance covered during the game were measured. As a results, Small-group games might be improve technique, and the games with large pitch area per player might be available for improvement in anaerobic power. Experiment 2 : Types of ball Methods and Results Sixteen male junior high school students participated in the present study. They played two types of 4vs4 games with changing the ball. (Game A : futsal ball ; Game B : football). The number of ball contacts, distance covered and heart rate during the game were measured. As a results, there was no significant difference in the number of ball contacts, distance covered and heart rate during the game between game A and B. Experiment 3 : Rule modifications Methods and Results Eighteen male junior high school students participated in the present study. They played three types of 4vs4 games with changing the rule. (Game A : free game ; Game B : pass game ; Game C : man to man game). The number of ball contacts, ratio of appearance time each movement speed, and distance covered during the game were measured. As a results, the pass game would be the most effective in developing techniques, and the man to man game might be available for improvement in anaerobic power and aerobic endurance. Conclusion These results suggest that the load characteristics of soccer game from the viewpoint of improvement in physical fitness differ greatly when the pitch area and player number, types of ball and rule modifications of games are changed. THE EFFECT OF NATIVE WHEY- VERSUS MILK-PROTEIN SUPPLEMENTATION ON MUSCLE SIGNALLING AND HYPER-TROPHY DURING STRENGTH TRAINING

HANDEGARD, V., HAMARSLAND, H., KÅSHAGEN, M., BENESTAD, H.B., RAASTAD, T.

Norwegian School of Sport Sciences

INTRODUCTION: Intake of dairy protein can stimulate muscle protein synthesis (MPS) after a bout of resistance exercise. The stimulation of MPS is driven by increased activity in anabolic signalling proteins, like phosphorylation of p70S6K. Leucine is suggested as a trigger for increased MPS. Consequently, protein sources giving a rapid increase in leucine concentration after ingestion might be beneficial for muscular adaptations to strength training. **AIM:** to investigate whether a native whey (100% whey-protein) supplement, known to rapidly increase leucine concentration, augments activity in anabolic signalling pathways more than milk protein (20% whey – 80% casein), and if this translates to increased hypertrophy and strength during 12-weeks of strength training. **METHODS:** 22 men and women (30±6 years) were randomized to either a milk protein or a native whey supplemented group. Both groups performed heavy load strength training for 12 weeks (3 sessions/week). In the first and last exercise session, biopsies were collected 30 minutes before and 2 hours after exercise to investigate acute responses and training adaptations. Protein supplements were given immediately after each session, in addition to morning or afternoon (2 x 20 g/day). Muscle samples were analysed for hypertrophic signalling and fibre area. Muscle strength and thickness of m. vastus lateralis were measured before and after training period. **RESULTS:** P-p70S6K increased significantly pre to post exercise for both groups in the first session and a significant larger response was observed in the native whey group than in the milk-group (9-fold vs 4-fold, respectively). However, in the last training session there was no significant difference between groups in P-p70S6K. There was no change in P-eEF2, whereas P-4E-BP1 increased acutely in the last session for both groups. Both groups significantly increased muscle strength in chest press and leg press (27±9 and 33±15%, respectively), with no differences between groups. Furthermore, similar significant increases were observed in the native whey and milk protein group for type II fibre area (25±30 vs. 25±29%) and m. vastus lateralis thickness (11±7 vs. 12±6%, respectively). **CONCLUSION:** In accordance with our hypothesis, native whey supplementation increased p70S6K phosphorylation more than similar amounts of milk protein in the first training session. This difference was, however, not present at the end of the training period, indicating adaptive mechanisms. Furthermore, the lack of differences between groups in improvements in muscle size and strength, suggests that the initial superior effects of native whey supplementation on muscle signalling not was translated to superior training adaptations.

A COMBINATION OF ACUTE DYNAMIC EXERCISE AND FLAVANOL-RICH COCOA CONSUMPTION ADDITIVELY IMPROVE EXECUTIVE FUNCTION IN HUMAN

TSUKAMOTO, H.1,2, SUGA, T.1, ISHIBASHI, A.1,3, TAKENAKA, S.1, GOTO, K.1, EBI, K.1, ISAKA, T.1, HASHIMOTO, T.1

1 Ritsumeikan University, 2 Japan Society for the Promotion of Science, 3 Japan Institute of Sports Sciences

Introduction Executive function (EF) is acutely improved by dynamic exercise through neural activation in the brain [1]. In addition, memory function (MF) is acutely and chronically improved by dynamic exercise through increased brain-derived neurotrophic factor (BDNF) in serum [2]. On the other hand, neural activity in the brain during cognitive task is acutely enhanced by flavanol-rich cocoa consumption [3]. Moreover, enhanced BDNF signaling in vitro human Alzheimer's disease model is triggered by cocoa polyphenol [4]. Interestingly, habitual intake of cocoa flavanol (CF) can improve various cognitive abilities [5]. Therefore, we hypothesized that a combination of acute dynamic exercise and high CF (HCF) consumption additively improve EF and MF. To address this hypothesis, we aimed to examine the EF and MF following intake of HCF and exercise. Methods Ten young healthy male subjects were randomized to receive a HCF beverage (563 mg flavanols per beverage, 250 ml, 80°C) and an energy-matched low CF (LCF) beverage (38 mg flavanols per beverage, 250 ml, 80°C) 1 h before exercise in a single blind counterbalanced manner. Next, the subjects performed cycle ergometer exercise at 60% VO₂peak for 30 min. Subjects undertook a color-word Stroop task (to evaluate EF) and face-name matching task (to evaluate MF) at each time point (pre-intake, post-intake at 30 min, pre-exercise, post-exercise at 0 min, 30 min, and 1 h). Results The HCF significantly improved EF at 30 min post-intake compared with pre-intake ($P < 0.01$), while the LCF did not affect EF. Furthermore, as compared with pre-intake, the combination of the HCF and exercise significantly improved EF throughout the post-exercise recovery (i.e., 1 h). However, as compared with pre-intake, the combination of the LCF and exercise improved EF only for 30 min during post-exercise recovery. In terms of the improved EF, the size of the effect was significantly larger in the HCF than the LCF at each time point during the experiment except for post-exercise at 30 min ($P < 0.01$). On the other hand, the MF was only significantly improved post-exercise at 30 min in the LCF compared with the HCF ($P < 0.05$). Conclusion These results suggest that a combination of acute dynamic exercise and the HCF consumption additively improve EF, but not MF. References [1] Byun K et al. (2014) Neuroimage, 98:336-45. ACUTE COCOA FLAVANOL INTAKE, EXERCISE AND CEREBRAL HEMODYNAMICS IN HEALTHY ATHLETES

DECROIX, L., TONOLI, C., SOARES, D., HEYMAN, E., TAGOUGUI, S., MEEUSEN, R.

Vrije Universiteit Brussel

Purpose: Evidence exists that acute exercise-induced increases in cognitive function are accompanied by increased (cerebral) blood flow and increased BDNF levels. Acute cocoa flavanol (CF) intake may improve cognitive function, peripheral and cerebral blood flow at rest in humans. In animals, chronic CF supplementation induces cognitive enhancements, which are paralleled by elevated hippocampal BDNF levels. Therefore, this study investigated A) the effect of CF intake on cognitive function in combination with exercise and B) two factors, cerebral oxygenation and perfusion and BDNF, which are related to cognitive function. Methods: Twelve healthy, well-trained men ($\text{VO}_{2\text{max}} 63 \text{ ml/kg/min}$) participated in this randomized, double-blind, cross-over study. Participants performed a cognitive task (CT) 100 minutes after consumption of a 904 mg CF drink or placebo (PL), which was followed by a 30-min time trial and a post-exercise CT. Prefrontal near-infrared spectroscopy (NIRS) was applied during cognitive tasks and exercise to measure changes in oxygenated (ΔHbO_2), deoxygenated (ΔHHb) and total haemoglobin (ΔHbtot) and blood samples were drawn and analysed for BDNF. Repeated measures ANOVA (drink (PL/CF) x period (pre/post exercise)) was performed to detect changes in cognitive function, BDNF levels and cerebral oxygenation and perfusion during exercise. To estimate the effect of CF intake on cerebral oxygenation and perfusion during a CT before and after exercise, an analysis of Covariance (ANCOVA) was performed to adjust for day-to-day variability. Results: Reaction time was faster post-exercise (effect of period: $F(2)=36.4 \text{ p}<0.01$), but was not influenced by CF intake (no effect of drink/interaction). ΔHbO_2 during the CT at rest was increased by CF intake, compared to PL ($F(1)=7.1, \text{ p}=0.02$). ΔHbO_2 , ΔHHb and ΔHbtot increased in response to exercise (effect of period), but no effect of CF was observed (no effect of drink/interaction). During the post-exercise CT, ΔHbO_2 , ΔHHb and ΔHbtot did not differ between CF or PL intake. BDNF was higher post-exercise (effect of period: $F(1)=31.8, \text{ p}<0.01$), but was not influenced by CF intake (no effect of drink/interaction). Conclusion: CF intake did not alter cognitive function or BDNF at rest, but cerebral oxygenation was increased during a CT at rest. The beneficial effect of CF intake on cerebral oxygenation at rest was overruled by the strong exercise-induced increases in cerebral perfusion and oxygenation.

EFFECT OF HIGH VS. MODERATE POST-EXERCISE PROTEIN FEEDINGS ON RECOVERY OF MASTERS ATHLETES

DOERING, T.M.1, REABURN, P.R.1, BORGES, N.R.1, COX, G.R.2, JENKINS, D.3

1:CQUniversity, 2:Australian Institute of Sport, 3:University of Queensland

Introduction Following exercise induced muscle damage (EIMD), masters athletes appear to take longer than younger athletes to recover. Post-exercise protein feeding is a recognised recovery strategy for endurance athletes to accelerate glycogen synthesis and elevate muscle protein synthesis for muscle repair and remodelling. However, whether doses of protein recommended for younger athletes are appropriate for masters athletes is unclear. The present study investigated the effect of repeated high vs. moderate protein intakes post-exercise on the same-day recovery of peak isometric torque (PIT), cycling performance and perceptions of recovery following EIMD in masters triathletes. Methods Eight trained masters triathletes ($52\pm 2 \text{ y}, \text{ VO}_{2\text{max}}, 51.8\pm 4.2 \text{ mL/kg/min}$) participated in this study. Participants completed two experimental trials separated by seven days in a randomised, double-blind, crossover design. Diet was standardised for 24 h before each trial. Trials consisted of morning PIT testing and a 30 min downhill (-10%) run at an intensity of 70% of $\text{VO}_{2\text{max}}$; an 8 h dietary intervention followed, providing either a moderate protein intake (MPI; $3 \times 0.3 \text{ g/kg}$) or isocaloric high protein intake (HPI; $3 \times 0.6 \text{ g/kg}$). PIT testing and a 7 kJ/kg cycling time trial (TT) were completed at the end of the 8 h. Perceptions of fatigue and muscle soreness were recorded pre- and post-exercise. Results Magnitude-based inferences suggest a possibly beneficial effect (62%) of the HPI on cycling TT performance (10 s, $p>0.05$). The HPI attenuated the loss of PIT (-3.6%) from pre- to post-intervention, while a significant reduction in PIT (-8.6%) was observed with the MPI ($p<0.05$). The HPI provided a significant reduction in the perception of fatigue from pre- to post-intervention ($p<0.05$), while no effect was observed with the MPI. Discussion This study is the first to show that higher than recommended post-exercise protein intakes may facilitate physiological and perceptual recovery in masters athletes. Despite minimal effects on cycling performance, the recovery of PIT observed following the HPI in the present study suggests accelerated muscle recovery following EIMD; this may be beneficial to subsequent high intensity training (Twist & Eston, 2005). Furthermore, the present findings suggest a HPI post-exercise may reduce perceptions of fatigue, and thus facilitate an acute return to training. In conclusion, doubling the recommended post-exercise protein intake among well-trained masters triathletes provided no detrimental effect to acute cycling performance, and may attenuate loss of muscle force and perceptions of fatigue associated with EIMD. DIETARY NITRATE INTAKE IN WELL-TRAINED ATHLETES

JONVIK, K.L.1,2, WARDENAAR, F.C.1, NYAKAYIRU, J.2, SENDEN, J.M.G.2, VAN LOON, L.J.C.1,2, VERDIJK, L.B.2

1: HAN University of Applied Sciences, 2: Maastricht University

BACKGROUND Beetroot juice, as a carrier of dietary nitrate, has become a popular ergogenic supplement in athletes. However, we consume nitrate via many other foods and food groups in our diet. PURPOSE To assess dietary nitrate intake and identify the main food sources that contribute to daily nitrate intake in a large group of well-trained athletes. METHODS 553 Dutch well-trained athletes (226 women and 327 men) completed multiple web-based 24-h dietary recalls and questionnaires within a 2-4 week period. We calculated daily nitrate intake following an assessment of the nitrate content of various foods and food groups. Gender differences were analyzed using independent t-tests. Correlations between energy, nitrate and vegetable intakes were analyzed using Pearson correlations. Results are reported as mean \pm SD. RESULTS Habitual nitrate intake was $132\pm 87 \text{ mg/d}$ (range 19-525 mg/d). Daily nitrate intake tended to be higher in women vs men ($141\pm 90 \text{ vs } 127\pm 84 \text{ mg/d}; P=0.061$). Despite substantially lower total energy intake in women vs men ($9.0\pm 2.4 \text{ vs } 11.5\pm 3.2 \text{ MJ/d}; P<0.001$), total vegetable intake was higher in women vs men ($186\pm 142 \text{ vs } 136\pm 101 \text{ g/d}; P<0.001$). When corrected for energy intake, nitrate intake was substantially higher in women vs men ($15.7\pm 9.3 \text{ vs } 11.3\pm 7.2 \text{ mg/MJ}; P<0.001$). A positive correlation was observed between daily energy intake and nitrate intake ($r=0.27, P<0.001$), and an even stronger correlation between daily vegetable intake and nitrate intake ($r=0.75, P<0.001$). In accordance, the majority of habitual nitrate intake was consumed through ingestion of vegetables and fruit (including potatoes), accounting for 77% of total nitrate intake in women and 71% in men. Lettuce and spinach were the products contributing most. Only 2% of the athletes (10 out of 553) reached a daily nitrate intake above the standard supplement dose of 400 mg. CONCLUSIONS Well-trained athletes have an average daily nitrate intake of 132 mg (19-525 mg). Dietary nitrate intake is significantly correlated with total energy intake and largely determined by the amount of vegetables consumed. Supported by a grant from the Dutch Technology Foundation STW

DIETARY NITRATE SUPPLEMENTATION AND EXERCISE TOLERANCE IN OBESE ADOLESCENTS

RASICA, L.1,2, SALVADEGO, D.3, PORCELLI, S.2, MARZORATI, M.2, MORETTI, S.2, SARTORIO, A.4, GRASSI, B.3

1University of Milan, Italy 2IBFM, National Research Council, Italy 3University of Udine, Italy 4IRCSS Istituto Auxologico Italiano, Italy

Aim: Previous study showed a higher O₂ cost of exercise, and therefore a reduced exercise tolerance, in obese patients during constant work-rate exercise compared to healthy subjects (Salvadego et al.). The ergogenic effects of dietary nitrate supplementation in sedentary healthy subjects has been often demonstrated: a) during moderate-intensity exercise, steady-state V'CO₂ was reduced; b) during high-intensity exercise there was a significant reduction in the amplitude of V'CO₂ "slow component" and time to exhaustion was increased (Jones). Aim of this study was to evaluate the effects of beetroot juice (rich in nitrate) supplementation on the main physiological variables associated with exercise tolerance in obese adolescents. **Methods:** Ten obese adolescents (age 16.2±1.1 yr; BMI 36.1±5.5 kg/m²) (Mean±SD) participated in a crossover double blind placebo-controlled study. Subjects were tested after 6 days of supplementation with beetroot juice (NO₃- 4.2 mM(BR) or placebo(PLA)). Participants performed: i) a cycle-ergometer maximal incremental test; ii) two repetitions of 6-min sub-maximal moderate (80%GET) constant work-rate exercise and iii) one high-intensity (65%ΔV'CO₂peak-GET) constant work-rate exercise until exhaustion. **Results:** Plasma nitrate concentration was significantly higher after BR (108.4±37.2 μM) vs PLA (11.9±3.3 μM). "Peak" values and the O₂ cost of moderate-intensity exercise were not different in BR vs. PLA. During high-intensity exercise, the amplitude of V'CO₂ "slow component" expressed as a percentage respect to total V'CO₂, at the same time in the two conditions, was slightly lower in BR(13.07±12.02 %) vs PLA(16.76±11.55 %) ($p<0.05$) and time to exhaustion was higher in BR(570±235 s) vs PLA(460±138 s) ($p<0.005$). **Conclusions:** The results of the present study suggest that, in obese adolescents, dietary nitrate supplementation may be effective in improving exercise tolerance only during high-intensity exercises. This is probably due to low oxygen availability and low pH, conditions that facilitate reduction from nitrite to nitric oxide. COCOA FLAVANOL SUPPLEMENTATION AND EXERCISE SCIENCE: A SYSTEMATIC REVIEW AND STATE OF THE ART.

TONOLI, C.1,2, SOARES, D.D.3, DECROIX, L.1,2, MEEUSEN, R.2, HEYMAN, E.1

1: ULille2 (Lille, France), 2: VUB (Brussels, Belgium), 3: UFMG (Belo Horizonte, Brazil)

INTRODUCTION. The overall goal of the current systematic review was to examine the effects of cocoa flavanol (CF) intake on exercise performance and physiological adaptations to exercise (acute and chronic) including markers of oxidative stress and inflammation, metabolic and (cardio) vascular parameters. **METHODS.** Pubmed and ISI Web of Knowledge were consulted to identify studies on CF intake and exercise. Key terms (and synonyms searched by MeSH database) that were included and combined were: 'exercise', 'polyphenols', 'flavanols', 'epi-catechin' and 'cocoa'. Studies in this systematic review needed to fulfill the following inclusion criteria: 1) humans, 2) original data 3) including cocoa flavanol and exercise, 4) no severe methodological deficiencies and 5) published before February 2016, 6) written in English. **RESULTS:** From a total of 522 studies, 8 met the inclusion criteria. Exercise performance (Time trial performance, VO_{2max}, HR,) and Rate of Perceived Exertion were not affected by the acute intake of CF. However, a 14-day intake of CF increases the gas exchange threshold during a VO_{2max} test. Some oxidative stress markers (F2 isoprostane, oxidized LDL's, MDA) were reduced by the acute or sub-chronic (14days) intake of CF. Markers of inflammation remained unaffected. Additionally, an increase in diastolic blood pressure during acute exercise has shown to be tempered in obese subjects by an acute high dose of CF intake (702 mg) compared to a low dose (22 mg), while flow mediated dilation increased after acute and chronic intake of CF. CF intake did not affect exercise-induced total platelet count or platelet volume. Furthermore, acute CF intake increased free fatty acids during exercise whereas RER, glucose, insulin, glucagon and cortisol levels remained unchanged. **DISCUSSION:** Based on this systematic review we conclude that CF intake is associated with reduced exercise-induced oxidative stress, tempered increments of blood pressure during exercise, increased mobilization of free fatty acids during exercise but without significant implication for exercise performance. Especially the amount of CF and time of intake is of great importance to have a specific action. Although CF does not increase exercise performance in young healthy subjects, one can expect improved performance in patients with vascular disorders. For more info contact ctonoli@vub.ac.be

PERFORMANCE AND SIDE EFFECTS OF ACUTE SUPPLEMENTATION WITH N-ACETYLCYSTEINE: A META-ANALYSIS

BRAAKHUIS, A., RHODES, K.

The University of Auckland

Background: N-acetylcysteine (NAC) is a promising antioxidant supplement with potential as an acute strategy to enhance performance in elite sport, but there are concerns about side effects with high doses. **Purpose:** To review current literature and evaluate the effects of NAC supplementation on sport performance and adverse side effects. **Methods:** The literature up to June 2015 was searched on MEDLINE (PubMed), EMBASE, SPORTDiscus, Google Scholar and Scopus databases to identify for all studies investigating the effects of NAC supplementation on exercise performance and/or side effects experienced. Performance outcomes from each study were converted to the percent effect equivalent to mean power output in a time trial. All pooled analyses were based on random effects models generated by Review Manager (version 5.3). **Results:** A total of 5 studies met criteria for inclusion in the sport performance meta-analysis, and 17 for inclusion in the side effects meta-analysis. The typical daily dose of NAC reported was 5.8 g.d⁻¹; with a range between 1.2 and 20.0 g.d⁻¹. The mean difference in performance was 0.45% (95% CI -0.79-1.69). The odds ratio of the side effects on NAC compared to placebo was 1.11 (95% CI 0.88-1.39). The sub-analysis of NAC dose suggests an increase in side effects as the dosage of NAC increased however this observation requires further investigation. **Conclusions:** Despite initially promising performance effects with NAC, at this stage it is premature to recommend further. The risk of side effects from NAC supplementation also remains unclear, due to significant variation in effects. Suboptimal reporting and documentation from studies make it difficult to meta-analyse current literature and make clear conclusions regarding the effect of NAC.

DIETARY NITRATE SUPPLEMENTATION ENHANCES RUNNING PERFORMANCE IN MODERATE NORMOBARIC HYPOXIA, INDEPENDENT OF AEROBIC FITNESS

SHANNON, O.1, DUCKWORTH, L.1, BARLOW, M.J.1, WOODS, D.1,2,3, SIERVO, M.2, LARA, J.2, O'HARA, J.P.1

1: Leeds Beckett University (UK), 2: Newcastle University (UK), 3: Royal Centre of Defence Medicine

Introduction Nitrate-rich beetroot juice (BR) reduces the oxygen cost of steady-state exercise and may improve exercise performance in sedentary and moderately-trained but rarely in well-trained individuals exercising at sea-level (Porcelli et al., 2015). Exposure to a hypoxic environment potentiates the nitrate-nitrite-nitric oxide pathway, and may extend the benefits of BR to well-trained individuals. The aim of this study was to determine the effect of BR on treadmill running performance in moderate normobaric hypoxia (equivalent to 2500 m altitude) in participants with a range of aerobic fitness. Methods Twelve males with a maximal oxygen uptake ranging from 47.1-76.8 ml/kg/min took part in a randomised double blind cross-over investigation. On the morning of the performance trials participants consumed 138 ml concentrated BR (~12.5 mmol nitrate) or a nitrate-deplete placebo (PL) (~0 mmol nitrate). Three hours later, participants completed moderate-intensity running and a 1500 m time-trial (TT) in a normobaric hypoxic chamber (PIO2: 107.5 mmHg, FIO2: ~15%). Plasma nitrite concentrations were measured pre-supplementation and immediately pre-exercise. Oxygen uptake (VO2) was monitored at rest in hypoxia and during moderate-intensity running. Arterial oxygen saturation (SpO2) was assessed pre-hypoxic exposure, pre-exercise, during moderate-intensity running and post-TT. Results Plasma nitrite was no different between conditions pre-supplementation (PL: 43.5±43.8 vs. BR: 34±34 nM), but significantly greater in BR immediately pre-exercise (PL: 70.3±59.1 vs. BR: 705.6±266.5 nM; P<0.05). Average VO2 was ~10 % lower (PL: 20.4±12.6 vs. BR: 18.4±2.0 ml·kg⁻¹·min⁻¹; P<0.05), whilst SpO2 was greater (PL: 86.5±3.3 vs. BR: 88.4±2.7 %; P<0.05) following BR. BR improved TT performance by 3.2 % (PL: 341.9±46.1 vs. BR: 331.1±45.3 s; P<0.05). However, there was no apparent relationship between aerobic fitness and the improvement in performance following BR ($r^2 = 0.05$). Discussion BR supplementation increases plasma nitrite, reduces VO2, elevates SpO2 and improves 1500 m TT performance in moderate normobaric hypoxia. There was no relationship between aerobic fitness and the response to BR supplementation. This suggests that well-trained and less well-trained individuals may derive the same performance enhancing benefits of BR when consuming a high nitrate dose, when conducting moderate and high-intensity exercise in a hypoxic environment. POST EXERCISE HIGH-FAT FEEDING INCREASES LIPID GENE EXPRESSION BUT SUPPRESSES P70S6K1 ACTIVITY: IMPLICATIONS FOR TRAINING ADAPTATION

HAMMOND, K.M., IMPEY, S.G., JEROMSON, S., HAMILTON, D.L., SHARPLES, A.P., MORTON, J.P.

Liverpool John Moores University

Introduction Carbohydrate (CHO) restriction augments training-induced increases in skeletal muscle mitochondrial biogenesis (Bartlett et al. 2015). Additionally, high-fat diets enhance the activities of enzymes involved in fat oxidation and transport (Erlenbusch et al. 2005). We therefore tested the hypothesis that reduced CHO availability but high fat availability provides an additive effect on the exercise-induced cell signalling pathways and gene expression responses associated with the regulation of mitochondrial biogenesis, lipid gene expression and muscle protein synthesis. Method Ten males completed a twice per day exercise model (3.5 h between sessions) comprising morning high-intensity interval (HIT) (8 x 5-min at 85% VO_{2max}) and afternoon steady-state (SS) running (60 min at 70% VO_{2max}). In a repeated measures design, runners exercised under different isoenergetic dietary conditions consisting of high CHO (HCHO: 10 CHO, 2.5 Protein and 0.8 Fat, g·kg⁻¹ per whole trial period) or reduced CHO but high fat availability in the post-exercise recovery periods (HFAT: 2.5 CHO, 2.5 Protein and 3.5 Fat, g·kg⁻¹ per whole trial period). Vastus Lateralis biopsies were obtained pre-HIT, post-SS and at 3 and 15 h post- SS exercise to assess muscle glycogen content, signalling activity of metabolic (AMPK-α2) and protein synthesis (p70S6K) transduction networks and expression of genes associated with mitochondrial biogenesis and lipid metabolism. Results Muscle glycogen was lower (P<0.05) at 3 h (251 vs 301 mmol·kg⁻¹dw) and 15 h (182 vs 312 mmol·kg⁻¹dw) post-SS exercise in HFAT compared to HCHO. AMPK-α2 activity was not increased post-SS in either condition (P=0.41) though comparable 2-3-fold mRNA increases (all P<0.05) in those genes associated with mitochondrial biogenesis were observed in both HCHO and HFAT: PGC-1α (3-fold), p53 (2-fold), Tfam (3-fold), PPAR (3-fold) and ERRα (3-fold). In contrast, the mRNA expression of CD36 (P=0.05) and CPT1 (P=0.03) was 1-2-fold greater in HFAT in the recovery period from SS exercise compared with HCHO. p70S6K activity was higher (P=0.08) at 3 h post-SS exercise in HCHO versus HFAT (72.7 ± 51.9 vs 44.7 ± 27 fmol·min⁻¹ mg⁻¹). Discussion We conclude that post-exercise high fat feeding does not "regulate the regulators" of mitochondrial biogenesis though it does increase lipid gene expression. However, high fat feeding suppresses p70S6K1 activity thus potentially impairing post-exercise skeletal muscle remodelling. As such high-fat post-exercise feeding offers no significant metabolic advantages for trained athletic populations. References Bartlett JD et al. (2015). Eur J Sport Sci 15: 3 – 12. PROTEIN INGESTION BEFORE SLEEP PROVIDES PRECURSORS FOR POST-EXERCISE OVERNIGHT DE NOVO MUSCLE PROTEIN SYNTHESIS

TROMMELLEN, J., HOLWERDA, A.M., KOOW, I.W.K., HALSON, S.L., VERDIJK, L.B., VAN LOON, L.J.C.

Maastricht University

Introduction Previously, we have demonstrated that ingestion of 40 g protein prior to sleep increases mixed muscle protein synthesis rates during post-exercise overnight recovery. It remains to be established whether ingestion of a more moderate amount of protein increases overnight muscle protein synthesis rates and provides precursors for de novo muscle protein synthesis. Purpose To determine

the impact of ingesting 30 g casein protein with and without 2 g free leucine prior to sleep on myofibrillar protein synthesis rates during post-exercise overnight recovery. Methods 36 healthy young males performed a single bout of resistance-type exercise in the evening (19:45 h) after a full day of dietary standardization. All subjects were provided with adequate recovery nutrition (20 g protein + 45 g carbohydrate) immediately after exercise (20:45 h). Thirty min prior to sleep (23:30 h), subjects ingested a beverage containing 30 g intrinsically L-[$\text{I}-\text{13C}$]-phenylalanine-labeled protein with (PRO+leu, n=12) or without (PRO, n=12) 2 g free leucine or a noncaloric placebo (PLA, n=12). Continuous intravenous L-[ring-2H5]-phenylalanine, L-[$\text{I}-\text{13C}$]-leucine and L-[ring-2H2]-tyrosine infusions were applied. Blood and muscle tissue samples were collected to assess whole-body protein balance, myofibrillar protein synthesis rates and overnight incorporation of dietary protein-derived amino acids into de novo muscle protein. One-way ANOVA with treatment as factor was used to determine differences between treatments. Results Protein ingestion prior to sleep improved overnight whole-body net protein balance (PRO: 53±7, PRO+leu; 59±12, and PLA: -6±1 mol·kg⁻¹ per 7.5 h; P<0.001). Myofibrillar protein synthesis rates did not differ between treatments and averaged 0.055±0.002, 0.055±0.004 and 0.057±0.003 %·h⁻¹, respectively (P=0.850). Myofibrillar L-[$\text{I}-\text{13C}$]-phenylalanine enrichments increased following protein ingestion and did not differ between the PRO and PRO+leu treatments. Conclusions Protein ingestion prior to sleep supports overnight recovery by providing precursors for de novo muscle protein synthesis during sleep. However, the ingestion of 30 g of casein protein with or without additional free leucine does not suffice to increase muscle protein synthesis rates during post-exercise overnight recovery. Funding The project is funded by TI Food and Nutrition, a public-private partnership on precompetitive research in food and nutrition. Contact jorn.trommelen@maastrichtuniversity.nl

EXERCISE ENHANCES THE OVERNIGHT MUSCLE PROTEIN SYNTHETIC RESPONSE TO PRE-SLEEP PROTEIN FEEDING IN OLDER MALES

HOLWERDA, A.M., KOUW, I.W.K., TROMMELLEN, J., HALSON, S.L., VERDIJK, L.B., VAN LOON, L.J.C.

Maastricht University

Purpose: The age-related decline in skeletal muscle mass is, at least partly, attributed to anabolic resistance to food intake. To compensate for anabolic resistance, we recently introduced the ingestion of dietary protein prior to sleep as a nutritional strategy to increase overnight muscle protein synthesis rates. Here we aimed to assess whether resistance type exercise performed in the evening can further augment the overnight muscle protein synthetic response to pre-sleep protein ingestion in older males. Methods: In a parallel group design, twenty-three healthy older men (71±1 y) were randomly assigned to ingest 40 g casein protein before going to sleep with (PRO+EX: n=11) or without (PRO: n=12) performing resistance exercise earlier that evening. Overnight protein digestion and absorption kinetics, whole body protein metabolism and muscle myofibrillar protein synthesis rates were assessed using primed, continuous infusions of L-[ring-2H5]-phenylalanine and L-[ring-2H2]-tyrosine with the ingestion of intrinsically L-[$\text{I}-\text{13C}$]-phenylalanine labeled casein protein. Results: Exogenous phenylalanine appearance rates expressed over time did not differ between treatments. A total of 55±2 vs 53±2% of the ingested protein-derived phenylalanine appeared in the circulation during overnight sleep in the PRO+EX and PRO treatment, respectively (P=0.49). Myofibrillar protein synthesis rates were 31% higher during overnight sleep when exercise was performed earlier that day (0.058±0.002 vs 0.044±0.003 %·h⁻¹ in PRO+EX and PRO, respectively; P<0.01; L-[ring-2H5]-phenylalanine). In line, approximately 27% more L-[$\text{I}-\text{13C}$]-phenylalanine was incorporated into myofibrillar protein in PRO+EX compared with PRO (0.042±0.002 vs 0.033±0.002 MPE, respectively; P<0.05; L-[$\text{I}-\text{13C}$]-phenylalanine). Conclusions: Resistance-type exercise augments the overnight muscle protein synthetic response to pre-sleep protein ingestion and allows more of the ingested protein to be directed towards de novo muscle protein synthesis during overnight sleep in older males.

THE RESPONSE OF MUSCLE PROTEIN SYNTHESIS TO WHOLE BODY RESISTANCE EXERCISE IS GREATER FOLLOWING INGESTION OF 40 G COMPARED WITH 20 G OF WHEY PROTEIN

MACNAUGHTON, L.S., WARDLE, S.L., MCGLORY, C., LAWRENCE, C., WALLIS, G.A., WITARD, O.C., TIPTON, K.D.

University of Stirling

INTRODUCTION It is currently accepted that ingesting 20 – 25 g of protein is required to achieve maximal stimulation of muscle protein synthesis (MPS) following resistance exercise. However, the influence of the amount of lean body mass (LBM) on the post exercise response of MPS to protein ingestion has never been investigated. Therefore, our aim was to assess the influence of the amount of LBM on the response of MPS to ingestion of either 20 or 40 g of whey protein following a bout of whole body resistance exercise. METHODS In a between and within groups study design, 15 young resistance-trained males of lower LBM (LLBM; ≤ 65 kg) and 15 of higher LBM (HLBM; ≥ 70 kg) were recruited. Participants consumed either 20 or 40 g of whey protein following a bout of whole body resistance exercise. Myofibrillar MPS was measured by the infusion of labelled phenylalanine tracer and collection of skeletal muscle biopsy samples. RESULTS Myofibrillar MPS was 18% greater following ingestion of 40 g (0.059 ± 0.017%·h⁻¹) whey protein compared with 20 g (0.049 ± 0.016%·h⁻¹) (p=0.005) during a 5 h exercise recovery period. No difference in the MPS response was observed between LLBM (0.048 ± 0.018%·h⁻¹ and 0.059 ± 0.021 for 20 g and 40 respectively) and HBLM (0.051 ± 0.014%·h⁻¹ and 0.059 ± 0.012 for 20 g and 40 g respectively) groups following whole body resistance exercise and protein ingestion. The rate of phenylalanine oxidation area under the curve (AUC) was greater (p=0.001) following ingestion of 40 g (15.53 ± 5.60 μmol·min⁻¹·kg⁻¹ × 300 min) compared with 20 g (12.83 ± 3.83 μmol·min⁻¹·kg⁻¹ × 300 min) of whey protein. DISCUSSION Our results suggest that more protein is required to maximally stimulate MPS when whole body exercise is performed compared with leg only. The amount of muscle activated during exercise, but not the total amount of LBM, alters the dynamics of protein nutrition. Further study is required to determine the amount of protein necessary to maximally stimulate MPS following whole body resistance exercise. Moreover, total LBM may influence the maximal response of MPS at higher protein doses. The novel finding of this study, i.e. that 40g of protein stimulates MPS more than 20g after whole body resistance exercise, has implications for design and implementation of nutrition strategies to support training and physical activity. We conclude that greater amounts of protein are required following whole body, compared to leg only, resistance exercise to maximally stimulate MPS. Introduction: The loss of skeletal muscle mass with aging has been attributed to the blunted muscle protein synthetic response to protein intake. Protein feeding prior to sleep has been suggested as an effective strategy to compensate for such anabolic resistance. We assessed the impact of ingesting 20 and 40 g protein prior to sleep on protein digestion and absorption kinetics and subsequent overnight myofibrillar protein synthesis rates in older men. **Methods:** 48 older men (72 ± 1 y) were randomly assigned to ingest 20 g protein (PRO20), 20 g protein plus 1.5 g leucine (PRO20+LEU), 40 g protein (PRO40) or a placebo (PLA) prior to sleep. Ingestion of intrinsically L-[$\text{I}-13\text{C}$]-phenylalanine and L-[$\text{I}-13\text{C}$]-leucine labeled casein was combined with intravenous infusions of L-[ring-2H5]-phenylalanine and L-[$\text{I}-13\text{C}$]-leucine throughout the night. Blood samples were taken frequently to assess dietary protein digestion and absorption kinetics, and muscle biopsies were taken prior to sleep and after 7.5 h of sleep to assess overnight myofibrillar protein synthesis rates. Plasma data were analyzed by two-factor repeated measures ANOVA (time as within-subjects factor, treatment as between-subjects factor) and differences in muscle protein synthesis data were analyzed by one-way ANOVA (treatment as factor), with Tukey post-hoc testing. Results represent means \pm SEM. **Results:** Exogenous phenylalanine appearance rates increased following protein ingestion, with more amino acids being released following ingestion of 40 as opposed to 20 g protein ($P < 0.05$). Overnight myofibrillar protein synthesis rates were higher in PRO40 when compared with PLA (PLA: 0.033 ± 0.002 ; PRO20: 0.037 ± 0.003 ; PRO20+LEU: 0.039 ± 0.002 ; PRO40: 0.044 ± 0.003 %/h, respectively; $P < 0.05$). The incorporation of dietary protein-derived amino acids into de novo muscle protein was greater in PRO40 when compared with PRO20 (0.033 ± 0.002 vs 0.019 ± 0.002 MPE, respectively; $P < 0.001$), and tended to be higher compared with PRO20+LEU (0.025 ± 0.002 MPE; $P = 0.06$). **Conclusions:** Ingestion of 40 g protein prior to sleep increases overnight amino acid availability and stimulates de novo muscle protein synthesis during sleep in older men. These findings provide a novel basis for nutritional strategies by providing additional protein to preserve muscle mass in both health and disease. Email: imre.kouw@maastrichtuniversity.nl

WHAT IS THE MOST RECOMMENDED ALTERNATIVE METHOD TO DXA TO ASSESS CHANGES IN BODY FAT PERCENTAGE IN ELITE YOUTH SOCCER PLAYERS?

ALCAZAR, J.I., MUNGUA-IZQUIERDO, D.2, RODRIGUEZ-GOMEZ, I.1, MARTIN-GARCIA, M.1, MAÑAS, A.1, VILA-MALDONADO, S.1, MENDEZ-VILLANUEVA, A.3, SUAREZ-ARRONES, L.J.2, ALEGRE, L.M.1, ARA, I.1

1:GENUD Toledo Research Group, Universidad de Castilla-La Mancha (Spain). 2:Section of Physical Education and Sports, Universidad Pablo de Olavide (Spain). 3:ASPIRE Academy for Sport Excellence (Qatar)

Introduction: Body fat percentage (BF%) has been shown to be an important item for talent identification (Reilly et al., 2000) and injury prevention in elite-standard youth soccer (Kemper et al., 2015). Our aim was to find out what are the most appropriate alternative methods to identify changes in BF% ($\Delta\text{BF}\%$) when dual-energy X-ray absorptiometry (DXA) is used as the reference method in elite youth soccer players. **Methods:** The sample was composed of 20 highly-trained youth soccer players (17.1 ± 0.5 y). BF% was measured in the preseason and in the middle of season (5 months after) by DXA [Hologic Serie Discovery QDR, USA], 2 bioelectrical impedance analyzers [Tanita BC-418 (TA), JP, and InBody770 (IB), KR], and skinfold thickness measurement using a Holtain caliper and estimating BF% through several formulas proposed in the literature [Slaughter (SLA), Faulkner (FAU), Carter (CAR), Durnin-Womersley (DW), Brook (BR), Withers (WIT), and Lohman (LOH)]. T test for dependent samples, intraclass correlation coefficient (ICC) and Bland-Altman analysis were used. **Results:** BF% measured by DXA was significantly decreased after 5 months of soccer competition ($11.4 \pm 2.6\%$ vs. $10.7 \pm 2.2\%$; $p < 0.05$). ICCs between $\Delta\text{BF}\%$ by DXA and alternative methods were: 0.53 (TA), 0.44 (IB), 0.83 (SLA), 0.70 (FAU), 0.74 (CAR), 0.79 (DW), 0.75 (BR), 0.87 (WIT), and 0.58 (LOH) (all $p < 0.05$). Bland-Altman analysis revealed a significant bias [95%CI] between $\Delta\text{BF}\%$ by DXA and $\Delta\text{BF}\%$ by IB (1.9% [5.7 , -1.9]), FAU (-0.6% [1.1 , -2.3]), CAR (-0.8% [1.0 , -2.6]), DW (-0.8% [1.0 , -2.6]), BR (-1.1% [1.1 , -3.3]), WIT (-0.5% [0.9 , -2.0]), and LOH (-0.7% [1.3 , -2.7]) (all $p < 0.01$), but not for TA (-0.5% [2.3 , -3.2]) and SLA (-0.3% [1.8 , -2.4]). The difference between DXA and IB, FAU, CAR, and LOH in estimating $\Delta\text{BF}\%$ was affected by the amount of $\Delta\text{BF}\%$ ($R^2 = 0.25-0.80$; $p < 0.05$). **Conclusion:** The equation of Slaughter et al., which includes triceps and medial calf skinfold thicknesses, seems to be the most recommended alternative method to DXA to assess $\Delta\text{BF}\%$ in young soccer players due to its moderate-high ICC and lack of significant bias with DXA. PROFILING MOVEMENT QUALITY CHARACTERISTICS ACCORDING TO BODY-MASS INDEX IN CHILDREN <9-11Y>

CLARK, C., BARNES, C., HOLTON, M., MACKINTOSH, K., SUMMERS, H., STRATTON, G.

Swansea University

Introduction: Obese children move less and with greater difficulty than their normal-weight counterparts (Stratton et al, 2007). This is a result of increased joint pressure, decreased mobility and detrimental modification of gait pattern (Nantel et al, 2006; Shultz et al, 2014). Whilst the effect of high BMI on cardiovascular fitness is well-known (Stratton et al, 2007), the effect on movement quality characteristics, in-field, has not been investigated. The aims of this study were first, to apply automated, novel analyses used in Nano-health, to characterise the movement quality of children during the multi-stage fitness test (MSFT), and second, to report how movement quality character-

istics cluster according to BMI. Methods One hundred and three children (10.3 ± 0.6 y, 1.42 ± 0.08 m, 37.8 ± 9.3 kg, BMI; 18.5 ± 3.3 kg.m 2) volunteered to take part and performed the MSFT whilst wearing an ankle mounted accelerometer. BMI groups were used to classify children as UW (<5th percentile, n = 7), NW (5th to 85th percentile, n = 73), OW (>85th to <95th percentile, n = 14) or OB (\geq 95th percentile, n = 9). The raw accelerometer signal was uploaded into MatLab and signal processed to derive characteristics of movement. All characteristics were profiled using a hierarchical clustering algorithm, Spearman's rho was used to assess the relationship with BMI group, and a Mann-Whitney U test was used to assess differences between BMI groups for each characteristic. Results Children from the OB group had significantly lower stride control than every other group ($P < 0.05$) and significantly lower TTE than UW and NW children ($P < 0.05$). Following application of a clustergram, BMI was clustered with stride profile and TTE was clustered with spectral purity. Further, significant negative correlations ($P < 0.05$) were found between BMI and TTE ($R = -0.25$), spectral purity ($R = -0.24$), maximal radial velocity ($R = -0.22$), stride angle ($R = -0.23$) and stride variability ($R = -0.22$). Discussion This was the first study to report the stride control of children's gait. Moreover gait analysis unveiled key performance characteristics that differed between BMI groups. Significantly, these were also (i) representative of children's performance during the MSFT and, (ii) significantly negatively correlated with BMI. Obese children were not able to alter stride angle or stride profile to meet the running demands of the MSFT. These results demonstrate that novel analytics of ankle accelerometry data identified movement quality characteristics specific to BMI groups whilst performing the MSFT. Additionally, not only does high BMI impact gait and cardiovascular fitness, it also impacts the fundamental frequency and harmonic content of movement. References Nantel J, Brochu M, Prince F. THE INFLUENCE OF MATURITY STATUS ON THE RELATIVE AGE EFFECT IN ELITE YOUTH ALPINE SKI RACING AND SOCCER IN AUSTRIA

MÜLLER, L.1, MÜLLER, E.2, PERNER, C.2, RASCHNER, C.1

1 University of Innsbruck, 2 University of Salzburg

Introduction A relative age effect (RAE), which consists of an over-representation of athletes born early in a selection year, was shown to be present in all age categories of alpine ski racing and soccer. Before strategies in the talent development systems can be changed to minimize the RAE, it is necessary to find the causal mechanisms of it. The aim of the study was to assess the influence of biological maturity status on the RAE. Methods The study included the investigation of 557 Austrian elite youth athletes (11-12 years): 134 (68 males, 66 females) national ski racers (SR) and 423 male soccer players (SP). Anthropometric measurements were performed, the age at peak height velocity (APHV) (Mirwald et al., 2002) was calculated and the birth months (divided into 4 relative age quarters (Q1-4)) were examined. Univariate ANOVA (post hoc: Scheffé) assessed differences in APHV between the athletes born in Q1-4. Chi²-tests evaluated differences in the Q-distributions and in the distributions of early (E), normal (N) and late (L) maturing athletes of the single Q. Statistical significance was set at $p < 0.05$. Results A RAE was present in SR ($\chi^2(3, N=134) = 12.09$; $p = 0.007$; $\omega = 0.30$) and SP ($\chi^2(3, N=423) = 33.09$; $p < 0.001$; $\omega = 0.28$). SR of Q1-4 did not significantly differ in APHV from each other ($p > 0.05$). SP of Q1-4 significantly differed in APHV (F(3, 419) = 10.86; $p < 0.001$); post hoc-tests revealed that SP of Q 3 and 4 had a significantly lower APHV than SP of Q 1 and 2. The distribution of E, N and L maturing SP and SP significantly differed from the expected normal distribution (SR: $\chi^2(2, N=134) = 23.36$; $p < 0.001$; SP: $\chi^2(2, N=423) = 67.63$; $p < 0.001$). SR of Q4 were N (65.2%; m: 41.7%; f: 90.9%) and E maturing (34.8%; m: 58.3%; f: 9.1%). The distribution of the SP of Q4 was N (56.9%) and E maturing (43.1%). Discussion A highly significant RAE was present among SR and SP. The biological maturity status (APHV) significantly influenced the RAE in soccer; the relatively younger SP (Q3-4) will reach their individual peak growth spurt at a younger age; they are more mature. In both groups the distribution of E, N and L maturing athletes significantly differed from the expected normal distribution with a high percentage of E and hardly any L maturing athletes (L (Q1-4): SR 0.7%; SP 2.4%). The relatively younger athletes of Q4 can counteract the relative age disadvantage and seem to only have a chance for selection for national races (SR) and performance centers (SP), when they are early or normal matured; late maturing relatively younger athletes seem to have no chance for selection. RAPID WEIGHT LOSS IN OLYMPIC COMBAT SPORTS

REALE, R.1,2, SLATER, G.2, COX, G.1,2, BURKE, L.1,3

1: Australian Institute of Sport, 2: University of Sunshine Coast (Australia), 3: Australian Catholic University

Introduction Olympic combat sports separate athletes into weight divisions. Official weigh-ins are held 3-24h before competition to ensure no athlete is heavier than permitted. Athletes commonly engage in rapid weight loss (RWL), generally via body water manipulation, before weigh-in then attempt to restore losses before competition on the assumption that performance decrements can be reversed. The belief is that a size/strength/leverage advantage is gained by competing in a division lighter than habitual body mass (BM). Whether RWL improves the chance of success or not is unclear. Thus the aim of these investigations was to examine post weigh-in BM gain (a reflection of RWL) and competitive success. We also collected data on body composition and methods used to achieve and reverse RWL to determine the necessity and suitability of common practices. Methods Olympic combat sport athletes ($n=94$) within 2w of competition had body composition assessed by dual energy x-ray absorptiometry and compared to weight division. Athletes ($n=227$) were surveyed on their aggressiveness of RWL and recovery habits via a previously validated questionnaire (Artioli et al. 2009) which quantifies a rapid weight loss score (RWLS). Post weigh-in BM gain was measured in judo ($n=86$) and boxing ($n=100$) athletes at competitions and compared among a variety of sub groups. Results All athletes were significantly heavier than their competitive weight division <2 w before competition. Athlete calibre had an effect on RWLS ($p=0.0042$) however sport and sex did not. Differences in post weigh-in BM gain between winners and losers, and medalists and non-medallists in judo were significant at 0.9 ± 0.3 % ($p=0.0021$) and 1.4 ± 0.4 % ($p=0.0026$) respectively. Increased recovery time resulted in differences in post weigh-in BM gain in boxers of $0.37\% (p < 0.0001)$. Surveys suggest athletes recognise the importance of recovery from RWL yet most do not understand optimal methods of recovery and rehydration. Discussion Many combat sport athletes engage in RWL to make weight, as loss of body fat alone appears inadequate particularly for lighter athletes. Athletes favour combinations of passive/active dehydration and reduced food intake. Higher calibre athletes engage in more aggressive RWL than lower calibre athletes. A strong association between post weigh-in BM gain and success exists in judo which is not found in boxing, possibly due to the shorter recovery time prohibiting meaningful BM fluctuations or the different activity profiles of the sports. Fighters are keenly aware of the importance of recovery and re-hydration post weigh-in but are in need of support to optimise their practices. References Artioli, G. G. et al. (2009). NUTRITIONAL PRACTICES AND CORPORAL COMPOSITION AS FACTORS THAT COULD DETERMINE THE DEVELOPMENT OF SPORT TALENTS IN ADOLESCENT SOCCER PLAYERS

BONFANTI, N., LUCENA, R., LORENZO, A.

San Jorge University

Introduction: Soccer practice is continually growing worldwide and the discover of new talents is a priority in this sport. It is known that there is a correlation between body composition (BC) and talent detection (TD) and when coaches select players, they tend to choose them with optimum BC. It is also known that when the soccer competition level increases, players become leaner, bigger and taller. Optimum BC depends of genetics but also have a direct correlation with nutritional intake (NI) of players. The aim was to analyze the correlation between NI and BC in two football teams with identical training load but different performance level and to observe the influence of NI and BC in TD. **Methods:** A descriptive study was carried out with 14 players (17.5 ± 0.7 years old) belonging to the same club: 8 playing in the higher level team (A) and 6 playing in the lower level (B) team, differentiated according to the subjective criterion of coach. NI was assessed with 7-day food diary (household measures, 3 days). BC was assessed by anthropometric (ISAK) and % fat mass and % muscle mass were calculated by formulas. (Poortmans et al., 2005; Slaughter et al., 1988) **Statistics:** for team comparison a Mann-Whitney U was used and Pearson's correlations were calculated between variables. Statistical significance was set at $p < 0.05$. **Results:** Players did not meet nutritional recommendations with a notably deficiency in carbohydrate intake (4.4 ± 0.5 g/Kg Weight (W)/day for team A and 4.5 ± 0.5 g/Kg W/day for team B). It has been observed a significant difference in protein consumption between team A and B (120 ± 13.1 g for team A and 105.2 ± 9.8 g for team B; $p < 0.05$). Moreover, team A had leaner bodies ($11.1 \pm 1.5\%$ fat mass (team A) vs. 17.8 ± 6.7 (team B) ($p < 0.05$) and it was a negative correlation between % fat mass and protein intake ($p < 0.05$) for both groups. **Discussion:** This study shows an important correlation between TD and BC as was described in previous studies with team sports (e.g.: Torres-Unda et al., 2013) and also between NI and some anthropometric parameters. Therefore, it could be assumed that exists an indirect relationship between nutritional intake of this athletes and TD, so that noncompliance with recommendations could be limiting the maximum potential development of this players and therefore cause a loss of potential talents. **References:** Slaughter et al., Hum Biol 1988, 60(5), 709-723 Poortmans J, Boisseau N, Moraine J, Moreno-Reyes R & Goldman S. MANIPULATION OF MUSCLE CREATINE AND GLYCOGEN CONTENT CHANGES DXA ESTIMATES OF BODY COMPOSITION

BONE, J.1,2, ROSS, M.1,2, TOMCIK, K.2, JEACOCKE, N.1, HAWLEY, J.2, HOPKINS, W.G.3, BURKE, L.1,2

Australian Institute of Sport

Introduction Reliable measurements of body composition can be achieved by dual x-ray absorptiometry (DXA) if a standardised protocol is followed (1, 2). The aim of this study was to investigate the effects of manipulating muscle glycogen (Gly) and creatine (Cr) content independently and additively on DXA estimates of lean body mass (LBM) and body fat. **Methods** Eighteen well trained male cyclists undertook a protocol involving parallel group application of Cr loading ($n=9$) (20 g/d for 5 d + 3g/d maintenance) or placebo ($n=9$) with crossover application of Gly loading (12 v 6 g/kg BM/d for 48 h) as part of a larger study involving a Gly-depleting exercise protocol. Body composition was measured via DXA using a standardised protocol involving rest and overnight fasting under the conditions of normal, depleted or loaded concentrations of muscle Gly, with or without Cr loading. Biopsies were performed on the vastus lateralis to measure muscle Gly and muscle Cr. Results Glycogen-depleting exercise on the day prior to DXA resulted in a most likely substantial decrease in total lean body mass ($-1.3 \pm 0.8\%$, $\pm 0.3\%$; mean \pm SD, 90% confidence limits). Additionally, very likely to most likely substantial increases in total LBM were observed following a Gly loading diet both with ($3.0\% \pm 0.7\%$, $\pm 0.4\%$) and without ($2.1\% \pm 0.9\%$, $\pm 0.5\%$) Cr supplementation, and with Cr supplementation alone ($1.3\% \pm 0.9\%$, $\pm 0.6\%$). Total body fat showed a very likely trivial change following glycogen depletion, but there were possibly substantial increases of 3-5% with Gly loading and/or creatine supplementation. **Discussion** These results confirm recent work that found that acute intake of a high carbohydrate diet to increased DXA estimate of total and appendicular lean mass in untrained men(3). Our study is the first to investigate the interaction between creatine and glycogen in well trained athletes, and show that these inventions may challenge the ability of DXA to determine real changes in muscle mass that might be meaningful to an athlete. **References** 1.Nana A, Slater GJ, Hopkins WG, Burke LM. ASSOCIATION BETWEEN PHYSICAL FUNCTION AND BODY COMPOSITION CHANGES AFTER A WEIGHT LOSS PROGRAM

LOZANO GUDIEL, S., CASTRO, E.A., BUTRAGUEÑO, J., ESTEVES, N.K., PEINADO, A.B., CUPEIRO, R.

Technical University of Madrid

Introduction Some studies have evaluated physical function as an important contributor to one's quality of life (Macdonald et al., 2012; Branco et al., 2016). However, few have been conducted after a weight loss program (WLP), combining perceived physical function and body composition (BC) changes (Florez et al., 2012; Cugusi et al., 2015). The aim of this study was to analyze the association between the physical function and changes in BC variables after a WLP. **Methods** One hundred and sixty-five (78 males and 87 females) overweight (W) and obese (O) participants (body mass index 25-34.9 kg/m²), aged 18-50 years, performed a weight loss intervention during 24 weeks. Subjects were randomized into three training groups (strength training, endurance training or a combination of strength and endurance; training frequency 3 times/week) or a physical activity recommendations group. All of them in combination with a 25-30 % caloric restriction diet. BC changes were measured with DXA (Zapico et al., 2012). Physical function was examined with the SF36 questionnaire. A three-way ANOVA with repeated measures and Spearman's correlations were conducted. The percentage of change was defined as (pre-post)/pre*100. **Results** Physical function improved significantly after the intervention (92.4 ± 8.87 vs 96.90 ± 0.54). There were no interactions among time (pre and post intervention), gender or groups. Interaction between time and BMI classification was found and overweight participants reported greater physical function than obese participants before the intervention (W: 95.01 ± 1.00 ; O: 90.03 ± 0.91). Low but significant correlations were found between body composition changes and physical function, pre and post intervention ($p < 0.05$). **Discussion** Recent studies show an association between BC and physical health, related to quality of life (Castres et

al., 2010; Brostow et al., 2016). Our results also indicated a relation between physical function and fat mass, android fat mass and lean body mass percentages. There was an increment in physical function perceived after the WLP, which is accordance to other investigations (Florez et al., 2012; Cugusi et al., 2015), and obese individuals observed a greater improvement than overweight individuals. Obesity had a negative impact on physical function; therefore obese individuals should be motivated to engage in physical activity and diet programs. References Branco, JC. et al. (2016). VERIFICATION OF BODY COMPOSITION BALANCE SUITABLE FOR LIFE BEHAVIOR IN FEMALE ART UNIVERSITY STUDENTS

HAYAKAWA, K., FUJII, K., ISHIGAKI, T., TANAKA, N., KASUYA, K.

Nagoya Management Junior College, Aichi Institute of Technology, Aichi Institute of Technology, Aichi University of the Arts, Tokai Gakuen University.

Introduction We can surmise that differences in the living environment greatly influence morphology. This study aimed to investigate the body composition balance of female art university students, who were thought not to have spent much time engaged in exercise or sports, considering not only their BMI but also fat and muscle accumulation rates based on morphological quality differences. Subjects The subjects were 102 female general university students (Control group), 59 female students at arts university A, and 68 female students at arts university B, totaling 229 individuals. The general university's female students were designated as the control group. Female art students at university B were taken to be students with strong backgrounds in the arts. Methods Estimates of body fat and muscle percentages with respect to BMI were sought for the control group using the least square approximation polynomial, and first- to third-order regression polynomials were derived. The general validity of these orders was then determined from the results of the coefficient of determination and the Akaike information criterion (AIC). We then investigated the differences in the body composition balance in terms of body fat percentage and the body composition balance in terms of muscle percentage by conducting the chi-squared test on the frequency distribution of the fat accumulation rate and muscle accumulation rate in the control and A and B groups. Results The validity of the third order fat and muscle percentage regression polynomial for the BMI measured in the control group was determined from the coefficient of determination and the AIC. In addition, after applying the data from the A and B groups in the constructed regression evaluation chart, we compared the fat and muscle accumulation rate frequency distribution with that of the control group and then conducted the chi-squared test on the results. The results show that the body composition balance for female students at the art university B, where there is greater specialization in the arts, included a higher number of cases wherein body fat and muscle accumulation rates for BMI was somewhat underdeveloped and muscle accumulation was somewhat overdeveloped. Discussion One may speculate that attaining a body composition balance suitable for one's lifestyle and behavior creates conditions that facilitate adjustment to the environment. From these results it seems that lower fat accumulation and higher muscle accumulation may be a physical characteristic of the female arts university students in the university with the stronger arts emphasis. This allowed us to evaluate body composition balance from the dualistic perspective of fat and muscle percentage with respect to BMI, and understand the physical characteristics of female art university students. k-hayakawa@nagoya-su.ac.jp

EFFECT OF 12 SESSIONS OF HIGH-INTENSITY INTERVAL TRAINING ON BODY COMPOSITION IN YOUNG ADULTS

ROMERO-ARENAS, S., VIÑUELA-GARCÍA, M., VERA-IBÁÑEZ, A., COLOMER-POVEDA, D., MÁRQUEZ, G.

Universidad Católica de Murcia

Introduction. High intensity interval training programs has shown to be an efficient way to improve body composition via activation of different metabolic and hormonal mechanisms. **Aims.** To examine the effect of four-week training of repeated sprints based on the Wingate test on power and body composition in young adults. **Methods.** Participants (22.4 ± 1.8 years) were randomly assigned to an experimental or a control group. Prior to and at the end of the training period, all subjects underwent a whole body densitometry scan and performed a Wingate test. The experimental group did 12 repeated sprint sessions, which consisted of three and six sprints of 30 seconds with 4 minutes of rest. The control group was instructed to continue with their daily activities without any intervention. **Results.** In the experimental group, the average and maximum power increased by 9.4-16.5% ($p < 0.001$). In addition, total fat mass decreased by 8.1% ($p < 0.028$) and abdominal fat mass decreased by 10.0% ($p < 0.038$). The control group showed no changes in any of the outcome measures. **Conclusions.** A four-week training of repeated sprints based on the Wingate test with a specific volume of ~3 minutes per session and a frequency of three sessions per week showed improvements in average and maximum power. Furthermore, high intensity interval training induced a lowering in total fat mass and abdominal fat.

Mini-Orals

MO-PM08 Environment

PASSIVE HEATING INDUCES SIMILAR BENEFITS IN AEROBIC CAPACITY AND INSULIN SENSITIVITY AS MODERATE-INTENSITY ENDURANCE TRAINING

HESKETH, K., LOW, D.A., STRAUSS, J., SHEPHERD, S.O., WAGENMAKERS, A.J., COCKS, M.

Liverpool John Moores University

Background: Evidence suggests adoption of a sedentary lifestyle leads to reductions in aerobic exercise capacity and insulin sensitivity and an increased risk for chronic disease. Public Health Authorities suggest 150 min of endurance training (ET) per week to prevent reductions in fitness and health. However, exercise may be contraindicated in some individuals. In these conditions passive heating (PH) has been suggested to be an alternative intervention to improve fitness and health, but hard evidence is lacking today. **Aims of the study:** To investigate: 1) The effect of PH on aerobic exercise capacity (VO_{2peak}) and insulin sensitivity compared to ET, and 2) whether increases in

skeletal muscle mitochondrial density and capillary density are part of the underlying mechanisms. Methods: 17 young sedentary males matched for age and BMI (21 ± 1 yr, BMI 24 ± 5) were randomly allocated to either 6 wk. of PH (n=10; 40-50 min resting at 40°C in a heat chamber, 3x/wk.) or ET (n=7; 40-50 min of cycling at ~65% VO₂peak, 3x/wk.). VO₂peak and insulin sensitivity (oral glucose tolerance test) were measured and muscle biopsies were taken from the vastus lateralis pre and post training. Immunofluorescence microscopy was used to assess fibre type (T1 and T2) specific changes in mitochondrial and capillary density. Results: VO₂peak (PH 5%, ET 5%; main effect P < 0.05) and insulin sensitivity (ISI Cedarholm; PH 14%, ET 30%; main effect P < 0.05) were both improved following training with no differences between PH and ET. Mitochondrial density was increased following training, with no difference between groups or within fibre types (PH T1 11%, T2 12%; ET T1 21%, T2 34%; main effect P < 0.05). PH and ET increased all measures of skeletal muscle capillarization, with no difference between fibre types (capillary contacts, PH 17%, ET 12%; capillary-to-fibre perimeter exchange index, PH 23%, ET 23%; capillary density, PH 23%, ET 22%; main effect P < 0.05). Both Interventions resulted in increased skin temperature during training (main effect P < 0.05), with no difference pre and post intervention. However, only ET increased core temperature during training (PH P = 0.366; ET P < 0.05). Conclusions: PH induced similar increases in aerobic exercise capacity and insulin sensitivity to ET. These physiological adaptations were accompanied by similar increases in mitochondrial and capillary density. This implies that PH increases 2 of the major determinants of aerobic capacity and insulin sensitivity at the skeletal muscle level to a similar extent as ET. In conclusion PH is an effective intervention to improve aerobic capacity and insulin sensitivity, inducing similar skeletal muscle adaptations to ET.

THE INFLUENCE OF DEHYDRATION ON THE TIME-COURSE OF HEAT ACCLIMATION AND TEMPERATE EXERCISE PERFORMANCE

NEAL, R., MASSEY, H., TIPTON, M., CORBETT, J.

University of Portsmouth

Introduction It has been suggested that adaptation to heat might be ergogenic [1] and that dehydration might represent an additional stimulus for plasma volume expansion and adaptation [2]. This study examined the effect of dehydration on the time-course of Heat Acclimation (HA) and temperate exercise performance. Methods A within-participant (n=8), balanced cross-over design with a three-month washout period was employed. Participants completed a control (euhydrated HA [HAEu]) and intervention (HA with permissive dehydration [HADe]) heat acclimation programme; dehydration was achieved by completely restricting fluid intake and a total of 1.75 L of fluid was provided during each session in the control condition. Thermal, thermoregulatory, physiological and perceptual responses to exercise in the heat (40°C , 50% rh) were assessed prior to, mid-way through, immediately following and one week after HA (eight daily 90 minute exercise and heat exposures where rectal temperature (Tre) was clamped at $38.5\text{--}38.7^{\circ}\text{C}$). A graded exercise test for determination of mechanical efficiency, blood lactate threshold (LT), maximal oxygen uptake (VO_{2max}) and peak power output (PPO) was performed in a temperate environment (22°C , 50% rh) pre- and post-HA. Results Long-term HA induced adaptation with a reduced Tre, heart rate, perceptual strain and augmented sweating when exercising in the heat, although there were no differences in the extent of HA or plasma volume expansion between HAEu and HADe. HAEu and HADe also reduced thermal and cardiovascular strain to a similar extent in a temperate environment following long-term HA. Graded exercise tests in a temperate environment suggest that PPO was improved following long-term HA but this did not differ between conditions and other variables such as mechanical efficiency, VO_{2max} and LT were unaltered. Conclusion Dehydration did not influence the HA response and the ergogenic benefits of HA were unclear. However, HA did induce favourable thermal, thermoregulatory, physiological and cardiovascular responses to exercise in hot and temperate environments in trained men. G., Rehrer, N. J., Patterson, M. J., Harrison, J., Sammut, I. & Cotter, J. D. (2014). Short-term heat acclimation is effective and may be enhanced rather than impaired by dehydration. *Am J Hum Biol*. 26: 311–320.

THE EFFECT OF NORMOBARIC HYPOXIA ON APPETITE, APPETITE REGULATING HORMONES & ENERGY INTAKE

MATU, J., DEIGHTON, K., ISPOGLOU, T., DUCKWORTH, L.

Leeds Beckett University

Introduction Acute exposure to very high altitude (>3500m) is associated with a significant suppression of appetite and energy intake, which may contribute to losses of lean mass and functional capacity. The reasons for this appetite suppression are unclear and it is unknown whether this will occur during acute exposure to moderate altitudes. This study examined the effects of exercise on appetite, appetite hormones and energy intake at moderate and very high altitudes. Methods Twelve healthy males (mean \pm SD; age 30 ± 9 years, body mass index 24 ± 3 kg.m $^{-2}$) completed three, 305-minute experimental trials at a simulated altitude of 0m (sea level: SL), 2150m (~15.8% O₂) and 4300m (~11.7% O₂) in a normobaric chamber. The trials were randomised using a counterbalanced Latin Square design. Participants arrived at the laboratory after a 12h fast, entering the chamber at 8am. A standardised breakfast was consumed inside the chamber at 1h. One hour after breakfast, participants performed a 60-minute treadmill walk at 50% of altitude specific VO_{2max}. An ad-libitum buffet meal was consumed 1.5h after exercise. Composite appetite score (CAS) ([hunger+prospective food consumption+(100-fullness)+(100-satisfaction)]/4), acylated ghrelin (AG), glucagon like peptide-1 (GLP1) and insulin were measured throughout. Results During the resting period prior to exercise there were no significant differences in any variables between conditions. During exercise, area under the curve (AUC) for CAS was significantly lower at 4,300m (33 ± 5 mm.h $^{-1}$) compared with 2150m (44 ± 5 mm.h $^{-1}$; p=0.024) but not compared with SL (42 ± 4 mm.h $^{-1}$; p>0.05). In the post-exercise period, AUC for CAS was significantly lower at 4300m (40 ± 19 mm.h $^{-1}$) compared with SL (55 ± 15 mm.h $^{-1}$; p=0.004) and 2150m (60 ± 14 mm.h $^{-1}$; p<0.001). During exercise, AUC for AG was significantly lower at 4300m (48 ± 23 pg.mL $^{-1}$.h $^{-1}$) compared with SL (69 ± 27 pg.mL $^{-1}$.h $^{-1}$; p=0.005) and 2150m (67 ± 31 pg.mL $^{-1}$.h $^{-1}$; p=0.01). During the post exercise period AUC for AG was significantly lower at 4,300m (49 ± 31 pg.mL $^{-1}$.h $^{-1}$) compared with SL (116 ± 49 pg.mL $^{-1}$.h $^{-1}$; p<0.001) and 2150m (111 ± 62 pg.mL $^{-1}$.h $^{-1}$; p=0.002). There were no differences in GLP1 or insulin between conditions. Mean energy intake was significantly lower at 4300m (3728 ± 3179 kJ) compared with SL (7358 ± 1789 kJ; p=0.007) and 2150m (7390 ± 1226 kJ; p=0.004). There was no difference in CAS, AG or energy intake between SL and 2150m. Discussion This study suggests that altitude-induced anorexia and a subsequent reduction in energy intake occurs with acute exposure to very high but not moderate altitudes. This effect may be explained by reduced concentrations of AG at very high altitudes. Further research should aim to identify methods of reducing appetite suppression at altitude.

PLASMA LEUCINE KINETICS UNDER CONDITIONS OF BOLUS AND INTERMITTENT FEEDING OF FREE LEUCINE IN YOUNG, HEALTHY MEN

HONE, M., EGAN, B.

University College Dublin

The maintenance, growth or loss of muscle mass occurs in response to the dynamic balance between muscle protein synthesis (MPS) and muscle protein breakdown (MPB) (1). Nutrition interventions that maximise the stimulation of MPS have application in recovery and athletic performance (2) and in addressing age-related loss of muscle mass in elderly (3). Leucine has been shown to be the key amino acid (AA) in the activation of signalling cascade of MPS (Morton et al. 2015). However, stimulation of MPS exhibits an upper limit in response to a given concentration of leucinemia (4,5) and a refractory response to sustained levels of high leucinemia (5,6). In contrast, strategic dosing and distribution of AAs with intermittent and pulse feeding can overcome this refractory response via cyclical oscillation of aminoacidaemia and leucinemia (6). However, few studies have observed the leucinemia after ingestion of leucine alone. During this study, the pharmacokinetics after a single bolus of 3g of leucine were compared to that of 1.5g of leucine followed by another 1.5g 2 hour after initial ingestion. The aim of this study was to determine the magnitude of the cyclical oscillation of leucinemia, and compare the area under the curve (AUC) for each condition. Ten healthy active males participated in an RCT with cross-over design of each of the following conditions: one single bolus feeding (BF) of 3 g leucine; intermittent feeding (IF) encompassing initial ingestion of 1.5 g leucine followed by 1.5 g leucine 2 h later; and a 3 g maltodextrin placebo (PLA). For 4 h after ingestion, plasma leucinemia remained unchanged during PLA, and averaged at 112 μ M. During BF, plasma leucinemia peaked after 30 min at 542 \pm 27.9 μ M ($p<0.05$). During IF, plasma leucinemia peaked after 30 min at 325 \pm 27 μ M, trended towards baseline levels at 169 \pm 8.6 μ M at 120 mins, and peaked again at 273 \pm 30 μ M 30 min after the second leucine ingestion ($p<0.05$). These results confirm that the oral ingestion of 3g of leucine, causes a steep rise in leucinemia to ~540 μ M at 30 minutes. 1.5g of leucine, delivered intermittently at 2 hour intervals, resulted in a cyclical oscillation of leucinemia, in which leucine concentrations had reached as low as ~170 μ M before the second ingestion at 2 hours. This dosing strategy may overcome the aforementioned refractory response of muscle, representing a strategy to maximise MPS in athletic and elderly populations. The present data support the aforementioned feeding strategies that will be employed in an upcoming trial in an athletic population examining recovery from intense resistance exercise. 1. EFFECTS OF SPRINT INTERVAL TRAINING UNDER HYPOBARIC HYPOXIC CONDITIONS ON METABOLIC CAPACITY AND HIGH-INTENSITY EXERCISE PERFORMANCE

OGITA, F.1, YOTANI, K.1, SHIOKAWA, K.1, TAGUCHI, N.1, TAMAKI, H.2

1 National Institute of Fitness and Sports (Kanoya, JAPAN), 2 Niigata University of Health and Welfare (Niigata, JAPAN)

Introduction Recently, many studies have reported that high-intensity or sprint interval training can improve not only anaerobic (glycolytic) metabolism but also aerobic (oxidative) metabolism and that these metabolic adaptations cause improvements in exercise performance. Also, training under hypoxic conditions has been primarily performed for the purpose of improving O₂ transport system, i.e. maximal aerobic power (VO_{2max}). However, several studies reported that maximal accumulated O₂ deficit (MAOD) and buffering capacity increased after altitude training (Mizuno et al. 1990, Ogita 2006), and the possibility that the hypoxic training may improve effectively anaerobic energy releasing system was suggested. Therefore, the present study aimed to examine whether very high-intensity, low-volume, sprint interval training (SIT) under hypobaric hypoxic conditions improve more effectively metabolic capacity and high-intensity exercise performance. Methods Fourteen healthy male students (22 \pm 1 yrs) were matched for baseline measurements into two groups and then randomized to normobaric normoxic training group (N, n=7) and hypobaric hypoxic training group (H, n=7). The subjects had a SIT using a bicycle ergometer, which consisted of five 5 s bouts at an intensity which cause exhaustion in around 10 s (~300% VO_{2max}) with a 10 s rest between each bout. SIT was conducted twice/day, 5 days/week, for 4 weeks, and H performed it under hypobaric hypoxic conditions corresponding to 4000 m above sea level. Before and after training, VO_{2max}, and MAOD, and intermittent exercise performance (IE; ten 5 s bout with a 20 s rest) were determined. Results After the 4 weeks of training, VO_{2max} significantly increased in N ($P<0.05$), but not in H. On the other hand, a significant increase was found in MAOD ($P<0.01$), total work in IE ($P<0.05$) in both groups. Furthermore, peak power output in IE increased significantly only in H ($P<0.05$). Discussion/Conclusion These findings suggest that the SIT used in this experiment could induce a large improvement of MAOD and high-intensity exercise performance in both conditions but that the SIT under hypobaric hypoxic conditions might be more beneficial to improve maximal power output. INFLUENCE OF SOLAR RADIATION ON ENDURANCE EXERCISE CAPACITY AND THERMOREGULATION IN A HOT ENVIRONMENT

OTANI, H.1, KAYA, M.2, TAMAKI, A.2, WATSON, P.3, MAUGHAN, R.J.4

1: Himeji Dokkyo University (Himeji, Japan), 2: Hyogo University of Health (Kobe, Japan), 3: Vrije Universiteit Brussel (Brussels, Belgium), 4: Loughborough University (Loughborough, UK)

Introduction It is known that environmental conditions have a large influence on fatigue and performance in exercising individuals and that endurance exercise capacity is impaired progressively as the ambient temperature (Galloway and Maughan 1997) and the relative humidity (Maughan et al. 2012) increases and the air velocity decreases (Saunders et al. 2005). Despite an awareness of the importance of solar radiation for endurance performance, especially in a hot environment, there has been no systematic investigation to confirm and quantify this effect. The present study investigated the effects of variations in solar radiation on endurance exercise capacity and thermoregulatory responses in a hot environment. Methods Eight male volunteers performed four cycle exercise trials at 70% maximum oxygen uptake until exhaustion in an environmental chamber maintained at 30 degrees C and 50% relative humidity. Volunteers were tested under four solar radiation conditions: 800, 500, 250 and 0 W/m². Rectal temperature, skin temperature (chest, upper arm, thigh and calf), heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. Results Exercise time to exhaustion was less on the 800 W/m² trial (23 \pm 4 min) than on all the other trials (500 W/m² 30 \pm 7 min; $P < 0.05$, 250 W/m² 43 \pm 10 min; $P <$

0.001, 0 W/m² 46 ± 10 min; P < 0.001), and on the 500 W/m² trial than the 250 W/m² (P < 0.05) and 0 W/m² (P < 0.01) trials. There were no differences in core (rectal) temperature, total sweat loss, heart rate, skin blood flow, cutaneous vascular conductance and percentage changes in plasma volume between trials (P > 0.05). Mean skin temperature was higher on the 800 W/m² trial than the 250 W/m² and 0 W/m² trials (P < 0.05), and on the 500 W/m² trial than the 0 W/m² trial (P < 0.05). The core-to-skin temperature gradient was narrower on the 800 W/m² trial than the 250 W/m² and 0 W/m² trials (P < 0.05). Conclusion The present study demonstrates that endurance exercise capacity in a hot environment falls progressively as solar radiation increases. This early fatigue in the higher solar heat load trials was associated with a higher skin temperature and a narrower core-to-skin temperature gradient. These observations suggest that solar radiation is a key consideration for individuals exercising in a hot environment. References Galloway, Maughan RJ. (1997). Med Sci Sports Exerc, 29, 1240-1249. Introduction: Short (< 7 days), prolonged (~ 60 min), submaximal heat acclimation regimens have been shown to induce physiological adaptations to heat exposure (Chalmers et al., 2014); however, pre-competition tapering traditionally involves periods of low volume, high-intensity training. The aim of the present study was to establish the effect of a high-intensity short-term heat acclimation (HISTHA) on heat adaptation parameters in trained cyclists. Methods: Thirteen trained male cyclists (37 ± 11 y; 184 ± 8 cm; 84 ± 8 kg; 60 ± 9 ml.kg⁻¹min⁻¹; 328 ± 37 Wmax) undertook 5 consecutive days of HISTHA. Each day involved a 6 min warm-up followed by ~12 x 1-min sprints at 100% Wmax separated by 1-min active rest, in the heat (35°C; 50% rh). Rectal temperature (Tr), heart rate (HR), power output (W), weighted-mean skin temperature (Tsk), rating of perceived exertion (RPE), thermal sensation (TS), sweat rate, haematological data, and ad libitum fluid consumption were recorded throughout. Effect sizes (g or r) were calculated from mean and standard deviations, or z scores and sample sizes, as appropriate. Results: There was no difference between day 1 and day 5 for the total work completed (332 ± 45 vs. 334 ± 39 W; g = 0.05). Thermal impulse was lower on day 5 (0.06 ± 0.01 vs. 0.05 ± 0.01°C.hr⁻¹; g = -0.97). When comparing day 1 with day 5, there was a small increase in Tr-rest (36.8 ± 0.5 vs. 37.0 ± 0.3°C; g = 0.47), Tr-mean (37.4 ± 0.3 vs. 37.5 ± 0.2°C; g = 0.38) and total voluntary fluid consumption (1.4 ± 0.6 vs. 1.6 ± 0.8 l.hr⁻¹; g = 0.27). There were small reductions in HRmean (149 ± 16 vs. 143 ± 13 b.min⁻¹; g < -0.40) and RPEmedian (16 (13-19) vs. 16 (13-19); r = -0.22), moderate reductions in TSmedian (7 (5-8) vs. 7 (5-8); r = 0.65), and large reductions in Tsk-mean and Tsk-peak (mean: 35.4 ± 0.5 vs. 35.1 ± 0.3°C; g = -0.70; peak: 36.4 ± 0.6 vs. 35.9 ± 0.4°C; g = -0.95). There was no effect on Tr-peak (38.1 ± 0.3 vs. 38.1 ± 0.3°C; g < 0.01), HRrest (73 ± 15 vs. 73 ± 14 b.min⁻¹; g < 0.01), Tsk-rest (33.9 ± 0.8 vs. 33.8 ± 0.6°C; g = -0.14), resting plasma volume (64 ± 6 vs. 63 ± 6 %; g = -0.15) or sweat rate (2.7 ± 1.1 vs. 2.6 ± 0.7 l.hr⁻¹; g = -0.11). Conclusion: A 5 day, 30-min HISTHA regimen improved HR, Tsk, and perceptual responses during exercise in the heat, but had no effect on plasma volume. The degree of change in thermoregulatory and cardiovascular variables was less than that typically shown with more prolonged low intensity heat acclimation protocols. References: Chalmers et al. MILD DECREASE IN SKIN TEMPERATURE INHIBITS HEART RATE ELEVATION DURING MODERATE EXERCISE, BUT DOES NOT AFFECT METABOLISM

KONISHI, M., TABATA, H., ANDO, K., KIM, H.K., NISHIMAKI, M., XIANG, M., SAKAMOTO, S.

Waseda University

Introduction Climatic terrain therapy can be applied to health promotion and is covered by insurance in Germany. Climatic terrain therapy is defined as 'walking in sloping terrain with mild body cooling (approximately 2°C decrease in skin temperature)'. Although the heart rate during exercise is useful to control exercise intensity, previous studies observed a reduction in the heart rate during exercise in severely cold environments compared to that in a neutral environmental condition (Gagnon et al., 2013). A characteristic of the climatic terrain therapy is a mild decrease in skin temperature during exercise at a neutral temperature (Schuh, 2012). The effects of mild body cooling on heart rate during exercise are not clear. Moreover, cold exposure enhanced fat utilization during exercise (Gagnon et al., 2013). Therefore, we investigated the effects of a mild decrease in skin temperature on heart rate and metabolism during exercise. Methods Ten men participated in this study (age: 27 ± 3 years, body mass index: 22.7 ± 2.5 kg/m²). They performed treadmill exercise of approximately 65% of maximal oxygen uptake for 60 min under two conditions: 1) mild body cooling condition and 2) control condition. In the mild body cooling condition, the participants wore half sleeve and shorts, and were sprayed cold water of approximately 10°C on by a sprayer with a breeze (1.5–2.0 m/s) during exercise. In the control condition, the participants wore half sleeve and shorts during exercise, without a spray or breeze. The experiment was conducted in a climatic chamber set at 25°C and 50% relative humidity. Rectal and skin temperatures were recorded during and after exercise. Heart rate and oxygen uptake were monitored during exercise. Blood samples for determining catecholamine, cortisol, free fatty acid, insulin, and glucose concentrations were collected before, immediately after, and 1 h after exercise. Results The skin temperature dropped by 1.7 ± 0.7°C in the last minutes of the exercise compared to that before exercise under the mild body cooling condition. There were no differences in rectal temperature between the two conditions. Although oxygen uptake during exercise or the blood parameters did not differ between the conditions, the heart rate during exercise was lower under the mild body cooling condition than under the control condition. Discussion The present study suggests that mild body cooling inhibits heart rate elevation during moderate exercise, but does not affect metabolism. References Schuh A. (1991). INDIVIDUAL HEMOGLOBIN MASS RESPONSE TO NORMOBARIC AND HYPOBARIC HYPOXIA

HAUSER, A.1,2, TROESCH, S.1, SAUGY, J.J.2, SCHMITT, L.3, CEJUELA, R.4, TRÖSCH, S.1, FAISS, R.1, MILLET, G.P.2, WEHRLIN, J.P.1

Swiss Federal Institute of Sport Magglingen

1: Swiss Federal Institute of Sport Magglingen (Switzerland), 2: University of Lausanne (Switzerland), 3: National Ski-Nordic Centre Prémanon (France), 4: University of Alicante (Spain) Introduction: A wide range of elite athletes use technical devices to simulate altitude

(normobaric hypoxia: NH) for altitude training. However, only little research compared the effect of altitude training in NH or at real altitude (hypobaric hypoxia: HH) on relevant physiological and performance responses (Hauser et al. 2015; Saugy et al. 2014). Therefore, the aim of the present study was to investigate whether hemoglobin mass (Hbmass) responses differ between an 18-days Live-High Train-Low (LHTL) training camp under either NH or HH. Methods: In a same subject crossover design with one-year washout, 15 male triathletes randomly performed two 18-days LHTL training camps either in hypobaric hypoxia (HH) or normobaric hypoxia (NH). All athletes slept at 2250 m and trained at altitudes <1200 m. Hbmass was measured in duplicate with the optimized CO-rebreathing method before (pre-) and immediately after (post-) each 18-day LHTL training camp, as well as at day 13 of the second training camp in HH (hypoxic dose matched to 18-day NH, n = 10). Results: Hbmass increased similar in HH (916 to 957 g, +4.5%, P < 0.001) and in NH (918 to 953 g, +3.8%, P < 0.001) after 18 days LHTL. Hbmass changes did not differ over time between HH and NH, neither after 18 days (P = 0.4) nor after the same hypoxic dose (P = 0.29). Absolute individual Hbmass responses ranged from -0.1 to +10.6% within HH and from -1.4 to +7.7% within NH. Discussion: We concluded that HH and NH evoked similar mean Hbmass increases for the same hypoxic dose (~230 h) and after 18-days LHTL. Within mean Hbmass changes there was a notable variability in individual Hbmass responses, indicating that individual Hbmass evaluation for altitude training in either NH or HH is relevant. THE RELATIONSHIP BETWEEN CYCLIC LOW-PRESSURE HYPOXIC ENVIRONMENTS AND PHYSIOLOGICAL RESPONSES DURING EXERCISE AND RECOVERY AFTER EXERCISE

NISHIMURA, K., NAGASAKI, K., SAKAI, M., MATSUBAYASHI, H., HAMANO, Y., MURAKAMI, H., TAKAMOTO, N.

Hiroshima Institute of Technology

Aim: We developed a cyclic low-pressure hypoxic environment system. The characteristics of this system were varied between decreased pressure at an altitude of 1,000 m for 150 s and increased pressure at an altitude of 0 m for 150 s; the atmospheric pressure was also changed periodically from 967 to 867 hPa (the external pressure was 1,008 hPa). Further, the relative concentration of oxygen was alternated between 20.9% and 18.5%. The present study aimed to determine the relationship between cyclic low-pressure hypoxic environments and physiological responses during exercise and recovery after exercise. Methods: The study included 15 healthy men, and they provided written informed consent before participation. All subjects performed a cycling exercise for 30 min and recovery after exercise for 10 min. The exercise protocol consisted of 20% of maximum oxygen uptake for 5 min (warm-up), 40% for 20 min (main-exercise), and 20% for 5 min (cool-down). We established two experimental conditions: exercise in the cyclic low-pressure hypoxic environment system (CLPH condition) and exercise outside the system (control (C) condition). Each condition was simulated on a different day. Heart rate (HR), blood pressure (BP), arterial blood oxygen saturation (SpO₂), rating of perceived exertion (RPE), and respiratory responses were measured in both experiments. Each subject participated in the two conditions in a random order 1 week apart. Results and Discussion: The SpO₂ during exercise was significantly lower in the CLPH condition than in the C condition. The HR and RPE at warm-up were significantly higher in the CLPH condition than in the C condition. However, HR and RPE during main-exercise and cool-down did not show a significant difference between the two conditions. There were no significant differences in BP during exercise between the two conditions. With regard to respiratory responses after exercise, the minute volume and ventilatory equivalent were significantly lower in the CLPH condition than in the C condition. No significant differences were observed in other respiratory response parameters during recovery after exercise. Previous studies have reported that the brachial-ankle pulse wave velocity in the cyclic low-pressure hypoxic environments was significantly lower than before the remained. Thus, cyclic low-pressure hypoxic environments may be useful in preventing metabolic syndrome diseases. Our results show that such environments can be considered an effective training method during highland stays. In conclusion, exercise in a cyclic low-pressure hypoxic environment enhances ventilation efficiency.

MO-BN03 Muscle - Tendon

MUSCLE-TENDON DYNAMICS AFFECT VALUES OF IDENTIFIED MUSCLE PROPERTIES

PENASSO, H., THALLER, S.

University of Graz

Introduction Whenever a person performs an intended movement there are interactions between active and passive elements. In simplified terms, activation dynamics recruit fibres of contractile elements (CE) which contract and thus interact with the serial elastic elements (SEE). Finally, the force produced by the muscle-tendon complex moves the bones/segments. As energy can be stored in the SEE, CE-SEE interactions could be important (Alexander and Bennet-Clark, 1977). Especially if the muscle-power at explosive movements is investigated, these interactions must be considered. We present a method to identify movement independent, individual muscle-tendon parameter values non-invasively and *in vivo*. Methods Non-linear parameter identification methods are applied to two models. The classic model A (Siebert et al., 2007) and its extension model B, adding a SEE and a force-length relationship, are used to show how CE parameter values change if they are allowed to interact with a SEE whose stiffness is identified at the same time. To identify individual parameter values of the knee-extensor muscle-tendon complexes of 14 male subjects (24.7 ± 3.8 yrs), datasets containing data from concentric dynamic and isometric maximum voluntary leg-extensions are processed at the same time. Results Comparing the identified values of the CE of models A and B showed differences in the curvature (A/FISO) and in the maximum efficiency (ME): A/FISO_A 0.3 ± 0.079 vs. A/FISO_B: 0.18 ± 0.075 (p <= 0.01, Hedges' g* = 1.5); ME_A: 0.27 ± 0.042 vs. ME_B 0.38 ± 0.07 (p <= 0.001, g* = 1.8). The identified SEE stiffness was 1777 ± 324 N/mm (889 N/mm for a single leg). Discussion The identification resulted in a mean SEE stiffness that is lower than literature values for the patellar tendon (e.g., 1837 N/mm [Kubo et al., 2006]). As it is not clear if the tendon and/or the aponeurosis are in series with the CE (Tilp et al., 2012), the stiffness of the aponeurosis could also be relevant (e.g., vastus lateralis 143 N/mm [Kubo et al., 1999]). Applying this value to each muscle of the quadriceps femoris results in 572 N/mm for a merged SEE. Thus our identified value is within the range from 572 N/mm to 1837 N/mm and may suggest that the SEE is a mixture of both structures. With model B the ME

increased towards values reported in literature (Nelson et al., 2011). We conclude that model B identified a more realistic set of parameters and thus is an improvement to model A. COMPARISON OF ULTRASOUND AND MAGNETIC RESONANCE IMAGING ASSESSMENTS OF THE ACHILLES TENDON CROSS-SECTIONAL-AREA

KRUSE, A.1, STAFILIDIS, S.2, TILP, M.1

University of Graz

1: KFU (Graz, Austria), 2: AU (Thesniki, Greece) Introduction Magnetic resonance imaging (MRI) and ultrasonography (US) are established, non-invasive diagnostic tools to evaluate Achilles tendon (AT) cross-sectional-area (CSA) (Pierre-Jerome et al., 2010). While MRI is the golden standard, US has several advantages when compared to MRI, e.g., cost and time efficiency (Rasmussen, 2000). To the best of our knowledge, previous assessments of AT CSA using MRI and US have not taken into account measurement and joint angle position nor US probe pressure, making direct comparisons challenging. Therefore, the purpose of this study was to compare MRI and US findings of AT CSA by use of a standardized protocol (SP). Methods Achilles tendon CSA of 15 subjects was assessed at 2 positions (distal, proximal) on 2 days using MRI and US. The SP for all investigations included a splint to fixate the ankle, markers to ensure the same measurement position during examinations, and minimal probe pressure for US image capturing. One image was conducted for each position and digitized on 3 consecutive days. The CSA was outlined manually and calculated automatically. CVs were computed to assess measurement accuracy. Method comparison was conducted by ICC, paired t-tests and Bland-Altman analyses (Bias±LoA). Results Reliability of image analysis judged by CV was $1.5\pm0.5\%$ and $1.6\pm0.7\%$ for MRI as well as $1.9\pm1.1\%$ and $1.6\pm0.9\%$ for US for the distal and proximal position, respectively. Mean values of AT CSA were $62.1\pm8.1\text{mm}^2$ and $57.6\pm8.0\text{mm}^2$ for MRI as well as $60.2\pm6.3\text{mm}^2$ and $54.4\pm7.5\text{mm}^2$ for US measurements. Comparison of the methods showed ICC values of 0.79 and 0.86 for the distal and proximal position. For the proximal position, the mean difference of both methods tested with a one sample t-test provided a significant ($p<.001$) systematic underestimation (3.3mm^2) of the AT CSA measured with US. Further, the paired t-test also showed a significant difference ($p<.001$) for this position. The Bias±LoA for the distal position was $1.9 [-7.1, +10.9]\text{mm}^2$. Discussion We attempted to exclude possible sources of error by using a SP, however, differences between MRI and US findings remained. Although ICCs demonstrate good correlations, a systematic bias exists for the proximal position. For the distal position, the MRI results may be 7.1mm^2 below or 10.9mm^2 above the US values representing 12 and 19% of the mean AT CSA. These differences are not acceptable for clinical purposes, and thus, the methods should not be used interchangeably. However, the CVs confirm that the analysing method used is reliable and we conclude that the AT CSA should be investigated with either MRI or US. HAMSTRING MORPHOLOGY AND STRENGTH REMAIN ALTERED 2 YEARS FOLLOWING A HAMSTRING GRAFT IN ACL RECONSTRUCTION

KONRATH, J., VERTULLO, C., KENNEDY, B., BUSH, H., BARRETT, R., LLOYD, D.

School of Allied Health Sciences, Griffith University, Queensland

INTRODUCTION: Hamstring grafts used in anterior cruciate ligament (ACL) reconstruction have been shown to lead to changes to the semitendinosus and gracilis musculature, possibly impacting on the morphology and strength of other muscle groups of the knee. This study examined the differences in knee muscle morphology and strength between the surgical and contralateral limbs in patients that underwent ACL reconstruction using a hamstring graft at two years post-surgery. We hypothesised that the loss of donor muscle size would significantly correlate with knee muscle strength deficits and that morphological adaptations would also be evident in non-donor knee muscles. METHODS: 20 participants (14 male, 6 female, 29 ± 7 years, 82 ± 15 kg) that had undergone a hamstring graft in ACL reconstruction at least two years previously, underwent MRI and subsequent strength testing. Using digitised three-dimensional mesh models of each respective muscle/tendon, muscle and tendon volumes, peak cross sectional area (CSA) and lengths were determined for 12 muscles and 6 functional muscle groups of the surgical and contralateral limbs. Peak isokinetic concentric torque was measured at $60^\circ/\text{s}$ in knee flexion/extension and internal/external tibial rotation. RESULTS: Only 50% of the patients regenerated both the semitendinosus and gracilis tendons, which were longer with larger volume and CSA compared to the contralateral side. The semitendinosus and gracilis muscles of the surgical limb both respectively demonstrated a 47% ($p<0.001$) and 36% ($p=0.002$) smaller volume, and a 24% ($p=0.014$) and 31% ($p=0.002$) smaller peak cross sectional area than the contralateral limb, as well as being 10.2 cm ($p<0.001$) and 5 cm ($p<0.001$) shorter. A 7% ($p<0.001$) larger volume was observed in the surgical leg for the biceps femoris and corresponded with a smaller internal/external tibial rotation torque ratio. The difference in volume, peak CSA and length of the semitendinosus and gracilis correlated significantly with the deficit in knee flexion torque with Pearson correlations of 0.51, 0.57 and 0.61 respectively. DISCUSSION: The muscle and tendon morphological properties of the semitendinosus and gracilis are substantially altered following harvest and these alterations underpin knee flexor weakness in the surgical limb. These deficits are only partially compensated by hypertrophy of other hamstring muscles, possibly affecting joint stabilisation and loading, and risk of re-injury and/or joint degeneration.

CHRONIC MECHANICAL OVERLOADING THROUGH WALKING, MARCHING AND JOGGING DOES NOT INDUCE CHANGES IN MUSCLE-TENDON MORPHOLOGY

BISSAS, A.1, HAVENETIDIS, K.2, METAXAS, T.I.3, CHRISTOULAS, K.3, CRONIN, N.J.4

1: Leeds Beckett University (UK), 2: Hellenic Army Academy (Greece), 3: University of Thessaloniki (Greece), 4: University of Jyväskylä (Finland)

Introduction Muscle-tendon morphological properties have been extensively examined in a wide range of populations (e.g. Stenroth et al., 2012). Also, adaptations to chronic mechanical loading have been studied but the focus has been mainly on resistance training effects (e.g. Arampatzis et al., 2007). This study examined the morphology of key biological structures in a special population group, who were exposed for a period of 3 years to a chronic constant overload of mechanical stress in the form of combined walking-marching-jogging under military conditions. Methods Eleven 4th year military cadets (age: 21.3 ± 0.5 years; height: $177.3 \pm 4.5\text{cm}$; mass: $72.2 \pm$

9.4kg) and eleven well-trained males (age: 21.6 ± 0.7 years; height: 176.8 ± 4.3 cm; mass: 74.6 ± 5.6 kg) were recruited to the study. Ultrasonographic measurements (ACUSON P300, Siemens) of muscle and tendon architectural characteristics were made by a linear probe (5.0 – 18.0 MHz) at 19 sites including Achilles tendon (AT) length, 4-site AT thickness (TN), AT cross-sectional area (CSA) and soleus (SOL) thickness. Statistical comparisons between groups and among sites were performed on absolute and normalised - for a range of anatomical lengths- values. Results The grand means for selected variables were: AT length (20.2cm), AT 3-site average TN (4.9mm), AT CSA (53.4mm²) and SOL TN (15.5mm). Absolute and normalised values for the above variables were not different between the two groups. In terms of AT thickness both groups exhibited the same pattern of thickness along the distal portion of the tendon, with the 4cm and 5cm sites proximal to the insertion to the calcaneal bone revealing significantly higher values (18% and 16% respectively, $p<0.05$) than those at the calcaneal notch. Discussion The findings indicate no adjustments in muscle-tendon morphological properties for structures subjected to a particular type of chronic mechanical overloading. Whilst the relevant military cadets undergo a standard annual volume of combined walking-marching-jogging activities in excess of 3,500km, it appears that either the total mechanical stress (over a period of 38 months in this study) or its intensity do not exceed an adaptation threshold sufficient to initiate structural changes. This does not rule out potential changes in intrinsic material and other architectural properties which govern mechanical behaviour and perhaps stimulate movement efficiency. STRUCTURE AND FUNCTION OF HUMAN FASCIA LATA: SITE-DEPENDENCE OF THICKNESS AND FIBER ORIENTATION

OTSUKA, S.1,2, OHMICHI, Y.2, OHMICHI, M.2, YAKURA, T.2, NAITO, M.2, NAKANO, T.2, KAWAKAMI, Y.1,2

1: Waseda Univ., 2: Aichi Medical Univ.

Introduction Thigh muscles are responsible for most of the daily physical activities, and covered with the fascia lata. Connective tissues surrounding a muscle have a mechanical role in lateral force transmission of up to 30% of muscle force (Huijing et al., 2003). However, characteristics of the deep fascia are not fully understood. To infer the functional relevance of the deep fascia, this study compared thickness and fibers' orientation of the fascia lata taken from different regions of the thigh of cadavers. Methods Specimens of the deep fascia of 4cm x 4cm in length and width each were collected from four regions (anterior, lateral, medial, and posterior) of the mid-thigh of 16 legs of 11 cadavers (6 males and 5 females, 75 - 92 years). Thickness of each specimen was measured with a caliper. Each specimen's surface was examined with a stereoscopic microscope and the distribution of fibers' orientation angles was determined. Then the angles were divided into four directions (longitudinal, transverse, positively diagonal, and negatively diagonal). The fractions of the fibers' orientation for each site were compared with one-way ANOVA ($p<0.05$, post-hoc test: Bonferroni). Results The deep fascia of the lateral region (0.80 ± 0.15 mm) was significantly thicker than those of anterior (0.28 ± 0.10 mm), medial (0.19 ± 0.04 mm), and posterior (0.24 ± 0.06 mm) regions. The fraction of longitudinally directed fibers were larger than other directions for all regions except for the posterior aspect. On the lateral region, 32.3 ± 2.6 % of the fibers were in longitudinal direction which was significantly higher than other directions. The distribution of fibers' orientations showed substantial variability among regions. Discussion The thickest deep fascia on the lateral region includes the iliotibial tract tightly attached to the deep fascia on the lateral side. The deep fascia of the lower limb is composed of interwoven bundles of collagen fibers (Gerlach et al., 1990), and the fibers' orientations reflect their mechanical loading (Steccio C et al., 2010). It was found that the majority of the fibers were in the longitudinal direction, which suggests highest stress occurring in this direction (especially on the lateral side) during daily activities. The variety of fibers' orientations may allow the deep fascia to effectively support or limit various movements of underlying muscles, which presumably makes physical activities more efficient. EFFECTS OF A 10-WEEK PLYOMETRIC TRAINING PROGRAMME ON JUMP PERFORMANCE AND ACHILLES TENDON PROPERTIES

PENZER, F.1,2, LAURENT, C.1, BAUDRY, S.2, DUCHATEAU, J.1,2

Université libre de Bruxelles

Introduction Plyometric training using jump exercises that involve both ankle plantar flexor and knee extensor muscles has been shown to increase jump performance and Achilles tendon stiffness (Fouré et al. 2010). However, ankle joint moment, and thereby Achilles tendon loading, is greater during jump exercises performed with knee extended than flexed (Arampatzis et al. 2006). The knee joint angle during jumps may therefore influence Achilles tendon adaptations. This study investigated the influence of knee flexion on the adaptation of Achilles tendon stiffness in response to a plyometric training programme. Methods Twenty young adults participated in a 10-week training programme (two sessions/week) consisting of various plyometric exercises performed either with knees extended (group EXT, 10 subjects) or flexed (~90°; group FLEX, 10 subjects), with a progressive increase in the number of jumps per session (from 200 to 400 jumps). A control group (no training) was composed of six subjects. Jump height and contact time for drop jumps performed from 20, 40, 60, and 80 cm were measured before and after the 10-week period. In addition, Achilles tendon cross-sectional area (CSA) was measured and tendon stiffness estimated from the force-elongation relation obtained from the displacement of the muscle-tendon junction assessed by B-mode ultrasonography during plantar flexors contractions of different intensities. Results Performance during drop jump (jump height and contact time) increased ($p<0.05$) similarly for both groups (EXT: $21.3 \pm 15.4\%$; FLEX: $24.4 \pm 14.6\%$) after training, regardless of drop height. Similarly, tendon stiffness was increased by $32.7 \pm 27.5\%$ and $33.2 \pm 37.5\%$ for EXT and FLEX groups, respectively ($p<0.05$). In contrast, Achilles tendon CSA did not vary after the 10-week period in neither training groups ($p>0.05$). For all these parameters, there was no significant change in the control group. Discussion As tendon CSA did not change after training, the increase in tendon stiffness should reflect intrinsic changes of the tendon properties (Fouré et al. 2010). However, the degree of knee flexion did not induce specific training adaptations of the Achilles tendon in our experimental conditions. This suggests that part of the observed gain in drop jump performance might reflect an improved elastic energy storage-recoil process independent of the degree of knee flexion during plyometric training. MUSCLE MYONUCLEAR CONTENT CORRELATES WITH INTEGRATED MYOFIBRILLAR PROTEIN SYNTHESIS AND WITH MUSCLE FIBRE CROSS SECTIONAL AREA IN THE UNTRAINED AND TRAINED STATE

VECHIN, F.C., DAMAS, F., PHILLIPS, S.M., LIBARDI, C.A., LIXANDRÃO, M.E., JANNIG, P.R., ROSCHEL, H., COSTA, L.A.R., BACURAU, A.V., DE CAPITANI, M.D., SNIJERS, T.

School of physical education and sport

Tricoli,V., Parise,G., Ugrinowitsch,C. 1:USP (Brazil), 2:McMaster University (Canada), 3:UFSCar (Brazil) Introduction Resistance training (RT) results in periodic post-exercise increases in myofibrillar protein synthesis (MyoPS) which results in increases in fiber/muscle cross-sectional area (CSA) [1,2]. This process could be regulated by changes in myonuclear content (MNC) and/or MyoPS. The present work aimed to examine the relation between MNC and integrated MyoPS, fiber CSA (fCSA) and vastus lateralis CSA (VLCSA) before and after 10wk of RT. Methods Nine men (age 27 ± 3 years; body mass index $22.9 \pm 3.0 \text{ kg} \cdot \text{m}^{-2}$) performed 10-wks of lower limb RT (2 exercises, 3 sets each x 9-12 RM, twice a week, totaling 19 workouts). VL biopsies collected before and after RT period were evaluated for fCSA and MNC by immunofluorescence microscopy. Integrated MyoPS was evaluated using VL biopsies at pre and 48h post-first and last RT bouts by mass spectrometry coupled with a gas chromatography. VLCSA was assessed by sequential ultrasound images. The Pearson's product moment correlation was performed to assess variables associations. Results In the untrained state, MNC did not correlate with any variable (MyoPS: $r = -0.01$; $P = 0.98$, fCSA: $r = -0.32$; $P = 0.54$, VLCSA: $r = -0.36$; $P = 0.34$), while in the 10 wk RT-trained state, MNC highly correlated with MyoPS (MyoPS: $r = 0.89$; $P = 0.001$). The MNC's change, at a trained state, highly correlated with the change in fCSA (fCSA: $r = 0.94$; $P = 0.02$), and demonstrated a trend toward correlation with increases in the VLCSA after RT (VLCSA: $r = 0.64$; $P = 0.06$). Discussion In the trained state, there is a specialization of protein synthesis according to stimuli [3], and we recently found that later in RT, there is a good agreement between MyoPS and hypertrophy (unpublished data). Our results here are in line with these observations and indicate that the myonuclear response to RT might also be adaptive with RT, since the MNC in the untrained state did not correlate with any variable evaluated, but in the trained state, there were significant correlations between MNC and MyoPS/hypertrophy. These results suggest, we propose, an increasing role of MNC in MyoPS increase to support accretion of myofibrillar proteins promoting muscle fiber growth with RT. References [1] Bellamy et al. WEEKLY TIME COURSE OF MUSCLE VOLUME AND STRENGTH PARAMETERS IN RESPONSE TO A MUSCLE HYPERPHPHY TRAINING

BUBECK, D., BROWN, N., HÄUFLE, D., SCHMITT, S., ALT, W.

University of Stuttgart

Introduction The examination of strength training methods and the adaptation effects influences the daily work from trainers and athletes for optimizing performance as well as the knowledge of researchers who try to receive a deeper insight in the underlying mechanisms and effects of muscle cellular adaptation. To get knowledge about the adaptive mechanisms it is important to get knowledge about the time course of adaptation. In literature most of the studies only show pre- and post intervention measurement data. As a consequence of this no detailed statements about the chronological processes in adaptation to strength training can be given. Therefore the goal of our study was to give a detailed description of the time course of morphological and functional adaptation effects to a hypertrophy strength training intervention. Methods: The study was designed as a longitudinal case study over eight weeks of hypertrophy training and two weeks of detraining. Two subjects participated at the study and trained three times a week, and underwent a testing procedure once a week. The training consists of a two day split training program for the whole body with ten multi joint exercises within 8-10 RM for three sets. The training exercises for the M. quadriceps femoris were done at an Isomed 2000 using a multi-joint leg press and a single joint knee extension movement. The workload of each training session, set and repetition was documented. Each week before the training session measurements of the CSA of the M. quadriceps femoris (QF) using MRI scans (1.5 T MRI scanner Magnetom Avanto Siemens Healthcare), isometric maximum force measurements (iMVT), resting (RTT) and peak twitch torques (PTT) were taken. Results: Both participants increased the mean power performing the isokinetic knee extension movement nearly session by session within the eight weeks of training. Muscle volume of the QF increased by 4,5% to 15,4% during the eight weeks of training and peaked in week six for subject M and in the detraining week 1 for subject D. iMVT decreased over the first four weeks in both athletes and then starts raising over the baseline till the end of the study of about 5,7% for subject D and 0,4% for subject M. PTT showed different results during the training weeks: subject D never couldn't raise the values above the baseline whereas M showed higher values for the first time after 5 weeks of training. Nearly the same behavior was observable at the RTT values. Discussion: The results indicate that adaptations to intensive strength training are complex and nonlinear. The chronological sequence of the different analyzed parameters indicates that the individual reaction to the training stimulus can be totally different and depends on the moment the measurements are made.

CARDIORESPIRATORY FITNESS IS INVERSELY ASSOCIATED WITH ABDOMINAL FAT MASS AND LOW-GRADE INFLAMMATION, INDEPENDENTLY OF BMI; A CROSS-SECTIONAL STUDY AMONG 10,973 MEN AND WOMEN.

WEDELL-NEERGAARD, A.S.1, ERIKSEN, L.2, GROENBAEK, M.2, PEDERSEN, B.K.1, KROGH-MADSEN, R.1, TOLSTRUP, J.2

Rigshospitalet

Objective: The role of cardiorespiratory fitness(CRF) has to a large extent been ignored in the investigation of the metabolically healthy, but obese phenotype(Primeau et al. 2011). However, recent studies suggest that low physical fitness is an independent cause of accumulation of visceral fat(Olsen et al. 2008) and low-grade inflammation that leads to metabolic deterioration and a whole range of chronic diseases(Pedersen 2009). We hypothesise that abdominal fat mass and low-grade inflammation are inversely associated with cardiorespiratory fitness independently of BMI. Method: Data of 10,973 individuals from the general population, DANHES 2007-2008 (Eriksen et al. 2011), were used when investigating the BMI-independent associations between CRF, abdominal fat mass and low-grade inflamma-

tion. Multiple linear and median quantile regressions were performed. Results: In men, a difference in CRF level by +5 mL/min/kg was associated with a difference in waist circumference by -1.45 cm (95% CI: -1.55 to -1.35 cm; $p<0.001$) and a difference in high sensitivity C-reactive protein(hsCRP) by -0.22 mg/L (95% CI: -0.255 to 0.185 mg/L; $p<0.001$), independently of BMI. In women, a difference in CRF level by +5 mL/min/kg was associated with a difference in waist circumference by -1.15 cm (95% CI: -1.25 to -1.0 cm; $p<0.001$) and a difference in hsCRP by -0.26 mg/L (95% CI: -0.3 to 0.22 mg/L; $p<0.001$), independently of BMI. Conclusion: Irrespective of BMI, CRF was found inversely associated with the amount of abdominal fat mass and the levels of low-grade inflammation, suggesting that high CRF counteracts some of the detrimental metabolic consequences of obesity without a weight loss. Therefore, CRF may determine the metabolic status and help distinguish the metabolically unhealthy from the metabolically healthy but obese individuals in clinical settings. THE ESSENTIALS OF TRAINING DIARIES FOR PHYSICAL ACTIVITY QUANTIFICATION IN HEALTH PROMOTION – A WORKPLACE CLUSTER RANDOMISED CONTROLLED TRIAL

DALAGER, T.1, JOHNSTON, V.2, BOYLE, E.1, WELCH, A.2, LARKIN, J.2, O'LEARY, S.2, SJØGAARD, G.1

1: SDU (Denmark), 2: UQ (Australia)

Background: Exercise as medicine has been proven effective for many disorders. In a workplace setting, adherence among participants is a challenge since low adherence compromises effectiveness of exercise. Training diaries provide unique information on participants' adherence and dropout. The aim of this study was to determine drop out and adherence in a strength training intervention using training diaries. The effect on muscle strength/endurance and musculoskeletal pain was investigated. **Methods:** A total of 763 office workers were cluster-randomised to a training group, TG, or a control group, CG. CG attended health promotion information sessions one hour weekly. TG performed five strength training exercises (forward and backward neck bend, front and side raise, and reverse pull) for 12 weeks, 3x20 min sessions a week -three sets per session- with 1/3 supervised. Training diaries were completed with repetitions and resistances performed. Dropout was defined as missing two sequential weeks of training, and the time point for 25% dropout was determined by Kaplan Meier analysis. Adherence was calculated as number of attended training sessions in the diary out of a maximum of 36 sessions. Adherence $\geq 70\%$ was used in the dose-response analysis. Intensity of neck/shoulder pain last three months was evaluated by a 10-point numerical scale (0-9, 9=worst possible pain). Muscle strength/endurance was measured for neck flexion/extension and shoulder raise. Intention-to-treat (ITT) analysis and adherence dose-response analysis was performed by Wilcoxon test between groups with $p<0.05$ for significance. **Results:** Time point for the 25% drop out was week 10. Participants had an average adherence of 60%. Out of nine possible training sets each week, on average five training sets were completed (95% CI: 5.04-5.21). TG increased significantly neck flexion strength (mean \pm SD (16.4 \pm 22.0%)) and endurance (28.6 \pm 72.7%), neck extension endurance (30.0 \pm 100.3%), and shoulder raise strength (10.9 \pm 26.4%) and endurance (43.6 \pm 103.5%), compared with CG. Neck and left shoulder pain decreased significantly more (~ 0.5 points) among TG participants with adherence $\geq 70\%$ compared to those with adherence $<70\%$. **Discussion:** Specific strength training proved effective in improving muscle strength/endurance and decreasing neck/shoulder pain when adherence was $\geq 70\%$. A novel finding is the Kaplan Meier analysis showing 25% of the participants had dropped out at week 10, suggesting reinforcement of motivational initiatives already around week 8-9. Training diaries provide unique opportunities to examine the training volume that will contribute with important knowledge for future implementation of workplace health promotion interventions.

PERCEIVED INSTRUCTOR BEHAVIOR AND BEHAVIORAL REGULATION FOR EXERCISE. A CROSS-SECTIONAL STUDY IN HEALTH RELATED EXERCISE CLASSES

HERB, J., GIESS-STUEBER, P.

University of Freiburg

Introduction Based on Basic Needs Theory (BNT: Deci & Ryan, 2002), this study examined cross-sectional relationships between perceived instructor behavior, psychological need satisfaction and behavioral regulation for exercise. We proposed that need supportive instructor behavior in terms of care for individuals (CARE), feedback (FB), functional structure (FST), and activation (ACT) relate to need satisfaction and self-determined forms of motivation. Further, we proposed, that the relationship between instructor behavior and behavioral regulation is mediated through psychological need satisfaction. **Methods** Participants (n=100; 35 male/59 female/6 not specified) from back exercise classes in a local fitness studio completed measures of perceived instructor behaviors, satisfaction of the psychological needs for autonomy, competence and relatedness, and behavioral regulations for exercise (intrinsic, identified, introjected, and extrinsic). Mediation analysis was computed to estimate indirect effects (b) which will be reported with 95% BCA CI in square brackets. Results Need supportive instructor behavior was significantly positively correlated with intrinsic ($r=.374-.583$; $p=.000$) and identified regulation ($r=.293-.474$; $p=.000$) whereas we didn't find significant correlations between need supportive instructor behavior and introjected nor extrinsic regulation. Mediation analyses showed that when instructor behavior promoted autonomy and competence, individuals reported significantly more self-determined forms of motivation (intrinsic and identified). Effect sizes of indirect effects were medium to large in the expected direction: $b=.08$ [.004; .167] to $.38$ [.180; .635], kappa-sq=.10 [.010; .208] to $.29$ [.142; .454]. In addition there were significant medium negative indirect effects of feedback and functional structure on extrinsic motivation through competence satisfaction: $b=-.10$ [-.304; -.004] to $-.26$ [-.682; -.028], kappa-sq=.09 [.009; .248] to $.013$ [.017; .311]. Conclusions Findings indicate that need supportive instructor behavior is an important determinant for behavioral regulation for exercise and that this relationship is mediated by need satisfaction of individuals. Instructors and fitness professionals implementing future health related exercise classes may support physical activity by facilitating need satisfaction and self-determined motivation by providing care, feedback, functional structure and activation. The needs for competence and autonomy seem to be more relevant in the relationship of instructor behavior and intrinsic motivation than the need for relatedness. references Deci, E.L. & Ryan, R.M. INFLUENCE OF A NOVEL TWO DESK SIT-TO-STAND WORKPLACE ON SITTING TIME AND OVERALL PHYSICAL ACTIVITY

SCHWARTZ, B., BACA, A.

University of Vienna

Introduction Prolonged sitting is ubiquitous in modern society and linked to several diseases (Dunstan et al., 2012). To decrease worksite based sitting time (ST) height-adjustable desks are recommended. Common one desk sit-to-stand workplaces exhibit small ST reduction potential and compensational short-term loss of weekly physical activity (PA) (Mansoubi et al., 2016). Thus, the purpose of this study was to investigate the long term efficiency of a novel two desk sit-to-stand workplace on ST and overall PA. Methods Eighteen participants (55 % men, mean age = 36 yr., 100% office based) participated in a three-arm, one-year randomized crossover intervention study. Allocation was done via a regional health insurance, with data collection during Jan 2014 – March 2015. Intervention group subjects have been provided with traditional or two-desk sit-to-stand workstations, while control subjects did not experience any changes during the whole study duration. For estimating PA and ST the International Physical Activity Questionnaire (IPAQ-long) was used (Hagströmer et al., 2005). Results Pairwise comparisons with Bonferroni adjustments were performed to locate significant differences in ST and PA. At baseline, employees sat $11:02 \pm 2:02$ h/day and $74:06 \pm 11:06$ h/week. For sit-to-stand workplace users in comparison to baseline, the proportion of ST significantly decreased for working days (-190 min, $p < 0.01$) and weeks (-853 min, $p < 0.05$). There were no significant changes for control periods and the control group in ST for working days and weeks. Weekly overall and non-working PA (median: 3198 MET-min wk $^{-1}$) did not change within any group or time period. Discussion This study examines the effect of a novel two desk sit-to-stand workplace on ST and PA. It has been shown that concerns about a long-term compensational loss of weekly PA are baseless. Reductions in ST differ between individuals and are considerably larger than in comparable studies (Neuhaus et al., 2014). In our view, the main reason for this effect are behaviour change theory techniques (BCTs) indirectly implemented in two desk setups. Our findings are limited due to a small sample size, strong inclusion criteria and the volunteer recruiting process. Although it may be concluded that ST reductions for common employees are noticeably smaller, we assume that our two desk sit-to-stand workplace can be used to fulfil occupational ST recommendations. HEALTH PROMOTION AND PHYSICAL ACTIVITY IN THE HUNGARIAN HIGHER EDUCATION – AN EMPIRICAL OUTLINE AND INTENTIONS

SZÉKELY, M.

Eötvös Loránd University

Introduction The issue of health in the broad sense, that is, the well-being of the society as a whole at present and ensuring the same opportunities for the future generations. It is well known in our homeland that the health condition of the Hungarian population is at critical stage and life expectancy is well below those countries of the same development level. The quality of life of our children definitely depends on the country's decision makers, white collars as well as the situations and strategic plans of institutions that educate them. The good news is, that the majority of the factors affecting health can be influenced, are lifestyle-bound therefore are reversible. There are widely approved evidence-based initiatives at international level to explore health promotion-oriented status and elaborate conceptual changes. Most importantly, WHO's 'Health for All' global program states, that health depends much more on community initiatives, inter-sector co-operation and on setting social equality as a goal than merely on the contribution of professionals. Methods Researches to reveal the ways of adaptation of the global program of Health Promoting Universities in Hungary were carried out keeping both paradigm sin view. The way public opinion and within it young people relate to knowledge and to the institutions nourishing knowledge, the way these institutions operate and provide services as well as their development initiatives, lifestyle habits of the representative and online sample of the students, the content of the whole education portfolio as well as the professions that primarily influence social well-being are the factors forming the current Hungarian state of play. Results and discussion The thread running through the literature on health promotion that providing theoretical background is the restructuring of institutional management via a student-centric organizational development. This change will affect the triad of education, research and professional services (third mission) as well as such functions as operation, physical environment and inside services. Continuous restructuring of the Hungarian higher education system can only be executed if the goals set are independent of the changing environment and influencing forces but acceptable by all. The above studies and international examples serve as starting point. On the other hand, beside creating the concept it is a legitimate claim to draw up specific steps, in order to which there are excellent Hungarian cases, good practices. mozes@elite.hu

LONG-TERM EFFECTS OF THE HEALTH PROMOTION PROJECT "SKIPPING HEARTS" ON MOTOR SKILLS OF CHILDREN: THE "EVASKIP" STUDY

SCHULZ, T.1, MEYER, M.1, ENGL, T.1, THOMANDL, L.1, HOFMANN, H.1, GRAF, C.2, FERRARI, N.2, AL NAJEM, S.3, OBERHOFFER, R.1, POSTLER, T.1

1: Institute of Preventive Pediatrics, Technische Universität München, 2: Institute of Movement and Neurosciences, German Sport University Cologne, 3: German Heart Foundation E.V., Frankfurt am Main

Physical activity and motor skills are important aspects in health prevention. In the last years studies showed a decline of motor skills in children. Therefore, the prevention program "Skipping Hearts" was designed (as a school project) to increase physical activity and improve motor skills by using Rope Skipping. Now, after including more than 250000 children, the evaluation "EvaSkip" determines the effectiveness of "Skipping Hearts" to improve motor skills of children in the long run. Motor skills were tested at baseline (t0), after 4 months (t1) and after three years (t2). Flexibility parameters were shoulder flexibility (SF), stand and reach (SR); coordination parameters were one leg stand (OLS), Match-4-Point (M4-P) and lateral back and forth jumps (LBF). Data have been collected of 191 children at t3 (1493 children at t0 and t1). 97 children performed the Basic Workshop (BW, 90 minutes activity in Rope Skipping), 55 children took part in the Champion Program (CH-P, BW + 10 units à 45 minutes in Rope Skipping); 39 children served as the control group (CG). Repeated ANOVA measures were used to calculate changes in parameters over time between groups. In case of significant interactions, group comparisons and analysis of differences between mean values (t1-t0, t2-t0 and t2-t1) were performed with one factorial ANOVA. Significant interactions between time and group occurred in SF ($p=0.008$). From t0 to t2 SF-improvement (right arm up) was lower in BW (21.6%, $p=0.045$) compared to CH-P (43.8%). Time group interactions occurred in OLS ($p=0.004$), from t0 to t2 BW improved (51.3%) more in balance compared to CH-P (35.4%, $p=0.015$) and showed no difference compared to CG. Additionally, in t0 BW showed lower baseline value than CH-

P ($p=0.010$). SR ($p=0.532$), M4-P ($p=0.220$) and LBF ($p=0.430$) showed no differences in development over time between groups. Coordination increased over time in all groups: 33.8% for LBF and 50.2% for MP-4. The main results showed that the intervention program "Skipping Hearts" has little positive long term effects especially for coordination. However, even if there are small-term effects of the project, long term effects can only be achieved by changes in behavior of the children and situations on site. Contact: thorsten.schulz@tum.de

EFFECTS OF THE HEALTH PROMOTION PROJECT SKIPPING HEARTS ON CARDIOVASCULAR RISK FACTORS IN CHILDHOOD: THE LONG-TERM EVALUATION STUDY EVASKIP

THOMANDL, L.1, ENGL, T.1, MEYER, M.1, OBERHOFFER, R.1, GRAF, C.2, FERRARI, N.2, AL NAJEM, S.3, POSTLER, T.1, SCHULZ, T.1

1: Institute of Preventive Pediatrics, Technical University Munich; 2: Institute of Movement and Neurosciences, German Sport University Cologne; 3: German Heart Foundation E.V., Frankfurt am Main

The prevalence of obesity, hypertension or elevated body fat is increasing in children and enlarges the risk of following chronic diseases. A reason therefore is the growing number of inactive children. The project Skipping Hearts, a rope skipping intervention in schools (more than 250.000 children included) wants to increase physical activity, improve motor skills and reduce the risk of cardiovascular diseases. Now after 3 years, EvaSkip examines possible long-term effects of Skipping Hearts with regard to cardiovascular parameters. From 1493 children of the short-time evaluation, 191 children (age $2=12.1$ y; height $2=154.7$ cm; weight $2=43.7$ kg) have been included into the study (Oberhoffer et al., 2015). 97 performed a 90 minutes Basic Workshop (SH-B) in rope skipping, 55 received a Champion Program (SH-CH) with additional 10 units à 45 minutes. 39 children served as controls (CG). Body mass index (BMI), body fat, systolic (SBP) and diastolic (DBP) blood pressure, resting heart rate (RHR) and waist-to-height ratio (WHR) were collected triply (t0, t1 after 4 months, t2 after 3 years). Z-scores were calculated for BMI, SBP and DBP. Changes in parameters over time between groups were analyzed by Two-Way repeated measures ANOVA. Group comparisons and analysis of differences between mean values of t1-t0, t2-t0 and t2-t1 with one-factorial ANOVA were performed. Results are expressed with p-values (p), 95% confidence intervals (CI) and mean±standard deviation. Significant interactions of time and group resulted in DBP ($p=0.015$). From t1 to t2 zDBP of SH-CH increased less compared to CG ($p=0.020$; 95% CI: [-1.58;-0.10]) and SH-B ($p=0.017$; 95% CI: [-0.13;-0.10]). Additionally, in t2 DBP was lower in SH-CH [73.6 ± 9.3 mmHg] than CG [79.3 ± 8.6 mmHg]. Body fat, zBMI, zSBP, RHR and WHR showed no differences in interaction effects. In t0 the proportion of children with hypertonic values was 59.1% (zSBP) and 50.0% (zDBP), in t2 57.1% (zSBP) and 55.5% (zDBP). With 92.0% (t0), 92.6% (t1) and 90.5% (t2) non overweight children, the study population can be considered as normal weight. SH-CH seems to have a positive long-term effect in DBP compared to SH-B and CG, but not in BMI, body fat, SBP, RHR and WHR. A 90 minutes Basic Workshop is definitely not enough to cause changes in behavior pattern and thus cardiovascular parameters. However, qualitative studies have to show whether SH-CH achieves behavioral changes in children. References Oberhoffer R, Schulz T, Postler T. (2015). Dtsch Z Sportmed, 66, 175. MULTIDIMENSIONAL MOTOR SKILL ASSESSMENT IN PRESCHOOL CHILDREN – A CRITICAL ANALYSIS

GIERIG, A., FERRAUTI, A.

Ruhr Universität Bochum

Introduction: To address widespread child obesity, movement poverty and increasing numbers of children with cognitive developmental delay as a typical follow up problem of a lack in children's overall daily physical activity, several multidimensional motor skill test batteries are proposed as a valid, reliable, and practical method for monitoring motor development of preschool children. The present study was focused on a critical evaluation of a selection of these published tests. Methods: 23 healthy preschool children (female: n=11; male: n=12; age: 4.6 ± 0.7 yrs; height: 109.2 ± 0.7 cm, body mass: 18.4 ± 2.3 kg) participated in a total of 13 tests, including physical (10m Sprint (SP), Endurance Running (ER), Sidehopping (SH), Standing Long Jump (SLJ), Shoulder Flexibility (SF), Sit and Reach (SR)) and coordinative tasks (Rolling Ball Trail (RB), One Legged Stance (OLS), Balancing (B), Stringing Beads (SB), Change of Direction (CD), Catch a Bar (CB), Target Throw (TT)). After two preceding baseline measurements for instruction and familiarization reproducibility of the test results had been determined in a pre - posttest design. All items were transferred into a standardized total Fitness Score. Results: 3 items from a total of 13 individual tests were highly reproducible in accordance with the ICC (95% confidence interval). (ICC: SLJ: 0.90, OLS: 0.93, B: 0.98). A mean reliability could be shown for 4 items (ICC: RB: 0.77, SH: 0.84, ER: 0.85, SR: 0.86). No or moderate reliability occurred in 6 individual tests (ICC: TT: 0.38, SB: 0.42, SP: 0.46, CD: 0.51, SF: 0.59, CB: 0.59). The influence of anthropometric data on motor performance was calculated using multiple linear regressions. Age, height and body mass were an important predictor for the total Fitness Score (60.8% explained variation). Based on the results of an One-Way ANOVA, children aged 5 yrs (-0.60 ± 00.37) scored the highest values and therefore differ significantly from the 4 yrs. (-0.08 ± 0.42 ; $p \leq 0.05$) and the 3 yrs. (-0.58 ± 0.62 ; $p \leq 0.01$). No gender differences were found (m: 0.05 ± 0.65 ; w: -0.04 ± 0.64). Overall, 12 items correlated significantly with the total Fitness Score. A factor analysis yielded only one factor, on which 6 items with an explained variance of 71.21% are loaded. Discussion: Our results show that most of the physical and coordinative tests reached an insufficient reproducibility. A multidimensional testing in that age seems to be dispensable since different physical qualities were pointing in the same direction. Generally the acquisition of motor abilities in preschool children is facing considerable problems in concentration and motivation which interferes with scientific standardization.

EFFECTS OF PHYSICAL ACTIVITY LEVELS ON THE RESPONSE TO DIFFERENT KINDS OF STRESS

YANAGITA, S., KUBOTA, N., TAKANO, Y., TAKEDA, K.

Tokyo University of Science

Daily physical activity enhances stress resistance, and the responses to stress are influenced by physical activity levels. On the other hands, the stress responses differ depending on kinds of stress. It is well known that differential responses are frequently observed after receiving physical and psychological stress. It is thus possible that the effects of physical activity levels on stress responses are altered by different kinds of stress. In the present study, we investigated the effects of physical activity levels on the response to 3 kinds of stress in rats. Male Wistar rats were housed in the cages with or without attached running wheel for 4 weeks as physical active or inactive conditions. Based on the 4weeks running distance, the rats were divided into high and low active runners. Following a 4-weeks running session, the each rats received different kinds of stress, such as severe physical stress (electrical foot shock), mild physical stress (little restraint), or psychological stress (fear conditioning). We analyzed brain corticotrophin-releasing hormone, plasma ACTH, and corticosterone levels as indicators of central and peripheral stress responses. The results indicated that physically active conditions induced

some changes on brain corticotrophin-releasing hormone and corticosterone levels in all kinds of stress conditions. Especially, physical activity enhanced stress resistance following psychological stress compared to inactive condition. In the comparison of physically high active and low active rats, there is no significant difference between high and low runners in all measurements following severe stress condition. On the other hands, in the psychological stress condition, freezing time, which is an indicator of psychological stress response following fear conditioning, in the low runners were significantly higher than that in high runners. Furthermore, brain CRH levels in the low runner tended to increase compared to high runners after fear conditioning. Stress responses following to mild physical stress buffered in both high and low runners. The results of present study indicate that daily physical activity can change brain functions related to stress response following to several kinds of stress. Furthermore, physical activity levels can influence stress response to psychological stress, but not physical stress, and that daily physical activity can enhance stress resistance to mild stress independent on physical activity levels. Our results suggest that actually daily physical activity decreases stress response and enhances stress resistance, however these reactions may depend on the kinds of stress.

MUSCULOSKELETAL PAIN IN GERMAN ELITE ROWERS

BEULE, L., FETT, D., TROMPETER, K., PLATEN, P.

Ruhr-University Bochum

Introduction Rowing is a popular sport and considered to be among the most physically demanding endurance sports that require outstanding physiological attributes. It is characterized by a continuous repetitive motion stressing various anatomic areas continually depending on the stroke phase. The biomechanical demands of the rowing stroke and the high associated training volume produce repeated forces of high magnitude to the musculoskeletal system. Therefore, the aim of the present investigation was to identify prevalence of musculoskeletal symptoms in German elite rowers. Methods Prevalence of musculoskeletal pain was recorded in 86 elite rowers ($m=43$, $f=42$; 20.9 ± 3.7 yrs; 183.5 ± 8.3 cm; 76.8 ± 11.3 kg) by a standardized and validated questionnaire based on the Nordic questionnaire (Kuorinka et al., 1987). Lifetime prevalence (LTP) and point prevalence (PP) of musculoskeletal pain in nine different anatomic regions were determined. χ^2 -statistics were used to determine differences in musculoskeletal pain between gender. The Pearson correlation coefficient was used for analyzing the relation of age. Results The most frequently localization of pain was in the lower back. LTP for lower back was 87.2%, followed by neck (66.3%), knee (65.1%), shoulder (61.7%) thoracic spine (58.1%), wrist (53.5%), ankle (33.7%), hip (32.6%) and elbow (17.5%). The PP of musculoskeletal pain showed a similar distribution. Highest PP was found in lower back (47.7%) followed by neck (30.2%), wrist (24.5%), shoulder (23.2%), knee (22.1%), thoracic spine (19.8%), hip (15.1%), ankle (7%) and elbow (3.5%). Comparison of gender showed no significant differences instead of LTP of the wrist ($p=.022$). Analyzing the effect of the rowers age on prevalence of musculoskeletal pain no significant correlation were found. Discussion The investigation showed that most common regions of pain were in the lower back and neck. These findings are in line to other studies which reported predominantly low back pain in rowers. Bahr et al. (2004) reported LTP of lower back pain of 63.3%. Ng et al. (2013) actually found LTP of 93.8% in male and 77.9% in female rowers. High physical loads, repetitive mechanical strain, intermittent or continuous hyperflexion of the lumbar spine, high training volume and the sports-related physical requirement profile might be associated with the development of musculoskeletal pain and especially low back pain in elite rowers. The results of the present study indicate the necessity of specific prevention programs in rowers. Acknowledgement The study was supported by the Federal Institute for Sport Science, Germany (ZMVI1-080102A/11-18). References Bahr R. et al. (2004). Spine, 29(4), 449; Kourinka I. et al. (1987). THE AGGRAVATION OF FUNCTIONAL ANKLE INSTABILITY REDUCED THE JUMP PERFORMANCE.

MASUNARI, A., KUNUGI, S., YOSHIDA, N., MIYAKAWA, S.

Ibaraki Prefectural University of Health Sciences.

Introduction An ankle sprain is the most frequent injury in the field of sports. Functional ankle instability (FAI) often results from ankle sprains. FAI is reduced the sports performance, especially, jump performance. Subjects with FAI exhibit altered patterns of movement during single leg landing and took longer time to stabilize compared to healthy subjects. Rebound drop jump (RDJ) is one of the ballistic stretch shortening cycle (SSC) movement. SSC movement is important to sports movement. Subjects with FAI were longer contact time than control subjects. However, the changes of the RDJ performance to become severe of FAI were not clear. Methods Ninety-two male college football players participated in this study. They went through the medical check (MC) at 2014(pre-MC) and 2015(post-MC). FAI and RDJ were measured at the MC. Self-reported FAI was evaluated with the Cumberland ankle instability tool Japanese version (CAIT-J) (Kunugi et al. 2016). The leg were defined as "better leg" if the post-MC CAIT-J score was lower than pre-MC CAIT-J score, while the leg were defined as "worse leg" if the post-MC CAIT-J score was higher than pre-MC CAIT-J score. The subject performed RDJ from a height of 15cm for one leg (RDJ15) and 30cm for both legs (RDJ30). RDJ15 were performed by a dominant leg and a non-dominant leg (dominant leg; RDJD15, non-dominant leg; RDJN-D15). The flight time (FT), ground contact time (CT) and peak force (PF) were measured by Multi Jump Tester (DKH). The rate of post-MC/pre-MC were calculated and analyzed to compare to difference between better legs and worse legs using independent two sided t-test. Results In RDJD15, there was a significant difference for flight time between "better leg" group ($n=33$, $98.3\pm8.0\%$) and "worse leg" group ($n=25$, $94.0\pm8.0\%$). In RDJN-D15, there was a significant difference for flight time between "better leg" group ($n=35$, $98.1\pm8.1\%$) and "worse leg" group ($n=19$, $93.0\pm9.4\%$). In RDJ30, there was a significant difference for flight time between "better legs" group ($n=24$, $101.4\pm7.3\%$) and "worse legs" group ($n=14$, $94.4\pm7.7\%$). Discussion In the "worse leg group", the flight time were shorten compared to one year ago. For shorter contact times and higher jumps, the ankle workload needs to be increased (Zushi et al. 1995), and FAI decreases the SSC ability (Yoshida et al. 2012). Therefor the aggravation of functional ankle instability reduced the jump performance. References Kunugi S, Masunari A, Noh B, Mori T, Yoshida N, Miyakawa S. (2016). Disabil Rehabil, 1-9. SPORTS INJURIES IN GERMAN TOP LEVEL YOUTH ICE-HOCKEY – EPIDEMIOLOGY AND PREVENTION

GRAMSTAT, B., HENKE, T., PLATEN, P.

Ruhr-Universität Bochum

Introduction: Ice-hockey differs in dynamic, allowed body contact and equipment from other team sports. That's why players are exposed to a high risk of injury and particularly young players should be protected against avoidable injuries. Aim of the study was to analyse the epidemiology of injuries in German top level youth ice-hockey and to provide information about typical injuries, injury risk and the cause of injuries. Methods: All teams (298 players and 10 coaches) of the german ice-hockey junior league (DNL) take part in the study during season 2013/2014. The survey was carried out by means of questionnaires, which were filled in in presence of the interviewer. The questions covered - training and competition exposition (hours), - age, height, weight, playing position and - most recent injuries of the last 18 months (diagnosis, treatment and time-loss, injury situation, protective equipment, position on the field at the time of injury). Results: 173 players (age: 16.92 ± 1.0 years; height: 180.8 ± 5.9 cm; body mass 77.34 ± 7.6 kg) announced 141 injuries in the queried period (18 months) which were suffered to 64% in the competition and to 36% in the training. The most frequent injuries were concussions (13.5%), injuries of the acromioclavicular joint (11.3%) or the adductors (9.2%). Injuries of the shoulder had to be treated often inpatient (mean 2.8 days). In five of 31 cases it was necessary to operate. In the first half of the season 2013/2014 (3 months) the incidence for injuries in competition amounts to 0.38 injuries per game or 31.8 injuries per 1000 player-game hours. In the same period 15 players injured themselves in the training, it turns out an injury risk of 10.6 per 1000 training hours. Injuries of the adductors occurred to 75% in training sessions, mainly with the beginning of motion and/or while skating forward. According to the players 67% of the competition injuries were connected to irregular conduct of the opponent, though 73% of the breach of the rules wasn't penalized by the referees. Discussion: On the basis of the findings, prevention measures should be age-related and adapted to the proficiency level of the player. 65% of the competition injuries were provoked by body contact, in literature values are between 45 - 84 %. Irregular conduct must be penalized by the referees more strictly, referee's performance should be standardised in youth ice-hockey. Injuries of the adductors can be reduced by specific prevention measures. Fairness and the respect for the opponent should be accepted and considered by all players equally, players should be sensitised for it already in their early stage of ice-hockey education. Besides education campaigns can cause a change in thinking.

SHOULDER TIGHTNESS OF INTERNAL ROTATION ASSOCIATES WITH CLINICAL DOUBLE-CHECK: BOTH OF ULTRA-SOUND FINDINGS AND ELBOW PAIN CHECK

TASAKA, S.1, WADA, T.2, FUKUMOTO, T.3, YAMANO, H.4, TASHIRO, Y.1, MATSUBARA, K.1, MATSUSHITA, T.1, AOYAMA, T.1

1: Kyoto University (Japan), 2: Takita Hospital (Japan), 3: Kio University (Japan), 4: Minami-Osaka Hospital (Japan)

Introduction Among youth baseball players, elbow injuries commonly appear, and early detection and prevention of elbow injuries are important. Recently, ultrasound imaging has been used to detect elbow injuries with confirmed reliability (Harada et al., 2006). In epidemiologic researches, however, previous studies mostly have been used only a pain or rest period by pain as indication of injuries, not used precise check. The purpose of this study was to investigate the association between abnormal ultrasound findings besides elbow pain and physical tightness. Methods A total of 295 youth baseball players participated in this study. The demographic data was obtained by questionnaire. The passive range of motion of the shoulder (abduction, 90° abducted horizontal adduction, external and internal rotation), straight leg raising (SLR), 90° flexed hip internal rotation (HIR), and finger-floor distance (FFD) were measured. All participants were divided into two groups (injury and normal). Injury group included participants with abnormal ultrasound findings in lateral or medial elbow subchondral bone by using ultrasound equipment besides appearance elbow pain when passive stress test for elbow. The differences of two groups were compared by unpaired t-tests and Chi-square analyses. In addition, logistic regression analysis was conducted. Results 41 players were into injury group and 254 players were into normal group. In range of motion, 90° abducted internal rotation of the dominant shoulder and HIR of the step forward side in pitching were significantly less than those in the normal group ($p = 0.022, 0.045$). The result of logistic regression analysis, 90° abducted internal rotation of the dominant shoulder was significantly associated with injury even after adjusted for other factors ($p = 0.035$, OR: 0.983, 95%CI: 0.967-0.999). Discussion This study indicated that the deficit of 90° abducted internal rotation was independently risk factor for abnormal ultrasound findings besides appearance of elbow pain in stress test. It is reported that the deficit of internal rotation is caused by thickening and contracture of the posteroinferior capsule. And these occur in response to loads that act on it during the follow through in the throwing motion (Burkhart SS et al., 2003). In conclusion, preventing the deficit of 90° abducted internal rotation by stretching may prevent the abnormal ultrasound findings, elbow pain and following elbow injuries. THE RELATIONSHIP BETWEEN GLENOHUMERAL INTERNAL ROTATION DEFICIT AND INJURY RISK OF THE UPPER EXTREMITY IN BASEBALL PLAYERS

HUANG, Y.T.1, CHIANG, Y.J.1, WANG, Y.S.3, CHOU, P.H.1,2

1Kaohsiung Medical University, 2Kaohsiung Medical University Hospital, 3National Cheng-Kung University

Introduction Glenohumeral internal rotation deficit (GIRD) has been identified as a significant contributing factor to shoulder injuries (Cools et al., 2015). Relatively few epidemiological studies have examined the relationship between GIRD and injury risk of the upper extremity in Taiwanese baseball players. This study aimed to investigate whether the risk of injury correlate with GIRD in Taiwanese baseball players. Methods A total of 406 players with an average age of 16 years, an average height of 171 cm, and an average weight of 68 kg, participated in this investigation. All players were divided into 3 age groups: junior high school (12 to 14 y/o), high school (15 to 17 y/o), and university (18 to 25 y/o). GIRD was defined as a loss of 20° or more of IR angle of the throwing shoulder compared with the non-throwing shoulder. We investigated the following variables include age, player's position, and characteristics of injury (location, mechanism, and treatment). Data from the groups with and without GIRD were analyzed using Chi-square test to detect the relationship between GIRD and variables. Results The results showed that there were no significant differences between the incidence of GIRD and player's position ($p = 0.859$), and mechanism of injury ($p = 0.433$). Nonetheless, the incidence of injury was significantly higher in the university group, with the injury rate of 56.9%, 61.8% and 81.0% in junior high school, senior high and university, respectively ($p = 0.008$). The incidence of shoulder injury was also significantly higher in the university group, with the shoulder injury rate of 28.1%, 31.8% and 50.8% in junior high school, senior high and university, respectively ($p = 0.005$). The incidence of elbow and wrist injury did not show significant differences among the three age groups. Discussion The results of this study showed that the incidence of injury were significantly higher in the university players who had GIRD. The incidence of shoulder injury was also significantly higher in the university players. Therefore, special

training and stretching program may be necessary to reduce the risk of injury in baseball players. References Cools AM, Johansson FR, Borrm D. AN UNAPPROPRIATED EXERCISE TRAINING PROGRAM

BERNARDI, E., AGGIO, F., GRAZZI, G., SORINO, N., COGO, A.

University of Ferrara

Exercise training is a key component of pulmonary rehabilitation and should be prescribed by an exercise specialist competent in respiratory disease. We report a case of a 72 years COPD male (mild obstruction) with cardiovascular morbidity (myocardial infarction in 2004) referred to our outpatient clinic for excessive exertion dyspnea during exercise in the gym. In 2013, the patient performed a moderate-walking training program for 8 weeks, 2 one-hour sessions a week. At the end of the program, a home-based training was prescribed (speed 4.5 km/h, 30 min, 3/week). Later, he decided to attend the gym, following a non-supervised cardio-fitness program. He was in beta-blocker but the speed was adjusted by the trainer according to the heart rate (HR). Currently, he is training at 6 km/h, slope of 6%, complaining a worsening dyspnoea. At the moment of the visit, spirometry and EKG were unchanged. A cardio-pulmonary exercise test (CPET) was made, mimicking the training session at the gym. Protocol started at 3 km/h progressively increased until 4.4 km/h at a slope of 0%. After 8 minutes the test was stopped for oxygen desaturation (SpO₂ 89%). At that point, HR was 82 bpm (55% of HRmax); the anaerobic threshold was reached; CO₂ equivalent: 40; ventilatory reserve: 17 L; inspiratory capacity reduced from 2.58 L at rest to 1.55 L. The results of CPET can explain the causes of dyspnoea. Conclusion: An expert staff should supervise patients during the training session at the gym. In fact, this case emphasizes the inadequacy of monitoring only the heart rate during exercise in chronic patients and the importance of evaluating other data (i.e. SpO₂ and previous maximal exercise test) to plan and follow an exercise training program.

THE EFFECT OF SKIN SCUBA DIVING NITROX EAN 50 PROGRAM ON COGNITIVE DEVELOPMENT AND SOCIAL DEVELOPMENT IN PEOPLE WITH AUTISM

KWON, D.1, HWANG, Y.1, YOO, H.1, KIM, S.1, SHIN, K.1, MOON, S.1, SUNG, J.1, PARK, J.2, SO, H.3, PARK, H.4

1:Pusan National University/Busan, South Korea, 2:Youngsan University/Busan, South Korea, 3:Dongseo University/Busan, South Korea

4:Chonnam National University/Gwangju, South Korea

Introduction There are various studies showing that positive effects of participating in a skin scuba diving program for healthy participants however, to date it is difficult of find studies investigating the use of scuba diving program for people with autism. The primary aim of this study was to analyze the effect of the skin scuba diving nitrox EAN 50 program on cognitive and social development in people with autism. Additional aims were to provide preliminary data on the usefulness of such a program as a form of rehabilitative treatment to provide more opportunities for social participation and an improved quality of life for people with autism. Methods In order to achieve these research goals, measurement factors for standard values and standard deviation values were calculated for 10 people with autism . All the autistic participants were diagnosed in their local hospital and all lived in the Busan Metropolitan City in 2015. Matching sample T verification data analysis was used to verify the difference in standard values for each item before and after the program was conducted. IBM SPSS Statistics 21 was used to analyze the collected data. Results First, there was a positive correlation between the skin scuba diving program and an increase in motor skill abilities for the autistic participants. Second, the program had no effect on the language skills. Third, the skin scuba diving program showed a positive effect on the overall cognitive abilities of the autistic participants. Fourth, there was an improvement in the interpersonal relations. Fifth, the autistic participants were able to follow directions better after taking part in the skin scuba diving program. Sixth, there was a positive correlation between participation and their behavior. Seventh, participation in the skin scuba diving program had a positive effect on their ability to adapt to groups. Discussion These results show that participating in the skin scuba diving nitrox EAN50 program had an effect on a variety of sub-factors related to the cognitive and social development of people with autism. The results provide evidence for the idea that the EAN 50 program is useful as a rehabilitation program for people with autistic disabilities. Additionally, this program gives people with autistic disabilities the chance to stand shoulder to shoulder with their non-disabled peers by increasing their chances for social participation and furthermore will provide preliminary data that will be helpful for the creation of rehabilitation and treatment problems for people with autistic disabilities. MONITORING TRAINING LOADS IN HANDCYCLING – PREPARING FOR RIO 2016

ZELLER, S., ABEL, T., STRUEDER, H.K.

German Sports University Cologne

Aim Scientific literature containing training load monitoring in Paralympic sports is lacking. The aim of the present study was to analyze training loads in handcycling for the first time during a full competitive season of a multiple Paralympic medalist. Methods At the beginning of this observation in 11/2014 the featured handcyclist was 54 years old (classification: WH5, height: 1.78 m, body mass: 68.0 kg, body fat: 12.8 %). As a member of the German paracycling national team she won four medals in the 2008 and 2012 Paralympic Games. Aiming towards the 2016 Paralympic Games this study is focusing on the preparation and the competitive period of the 2015 season. Using a SRM-Powermeter every training session was recorded from 11/2014 to 09/2015. At the beginning of the observation and in may 2015 laboratory testing were conducted to determine training intensities. Training intensity was analyzed according to the five-zone intensity scale (Seiler, 2010) like shown in table 1. In addition to this scale the model of three intensity zones (1: below the individual lactate threshold (ILT), 2: between the ILT and the onset of blood lactate accumulation (OBLA), and 3: above the OBLA) was used to compare the present results with general results in the literature (Seiler, 2010). Results The athlete completed 186 handcycling training sessions in 382:28 hours, covered a distance of 8640.96 km, climbed 35611.0 m and burned around 145000 kj during the investigation. The intensity distribution according to the five- and three-zone intensity scale is shown. Conclusions Maintaining a high fitness level throughout the season was important to collect points for the qualification of the 2016 Paralympic Games. This aim was reached by winning every world-cup time-trial of the 2015 season. The analysis of the training intensity distribution shows a tendency to a greater volume in zone 2 than recommended in the literature (Esteve-Lanao et al., 2005; Seiler, 2010; Stögg & Sperlich, 2015). Therefore, a room for improvement for the upcoming Paralympic season was found. References Esteve-Lanao, J., Juan, A. F. S., Earnest, C. P., Foster, C., & Lucia, A. (2005). THE EFFECTS OF VIRTUAL AND TRADITIONAL GOLF PROGRAMS ON STRENGTH, FLEXIBILITY AND REACTION TIME IN CHILDREN WITH CEREBRAL PALSY

GERCEK, N., TATAR, Y., UZUN, S., RAMAZANOGLU, N., SANLI, G.

Marmara University

Introduction A regular lifelong physical therapy and rehabilitation program is required for reducing motor control problems in cerebral palsy (CP). Sports and virtual reality can be used as alternative enjoyable exercise methods. The aim of this study is to compare the effects of virtual golf training (VGT) and traditional golf training (TGT) on strength, flexibility and reaction time in children with CP. Methods 19 with CP (hemiplegia) ages 6-12 participated in this study. Subjects divided into two matching groups according to Gross Motor Function Measure: VGT (n:9) and TGT (n:10). For the assessment of muscle strength: hand grip, lateral step up and curl up tests; flexibility: sit and reach, modified appley and modified thomas tests and reaction time: anticipation time tests were used. These tests were done at baseline and after 12 weeks intervention. In this study, similar full swing training program used on both groups. Children attended to the training program for 60 minutes a day, 3 days a week during the 12 week. Results Within group comparison analyses, significant differences were found in hand grip strength test on the favor of TGT group ($p<0.05$). After 12 weeks training program both groups' sit and reach values, lower body and abdominal muscle strengths increased similarly ($p<0.05$). No significant increases were found on modified appley and thomas tests for each group ($p>0.05$). Discussion Higher positive changes on hand grip strength in TGT group than VGT group shows the importance of using heavy materials which increases the muscle strength on bimanual exercises. Lower extremity strength increased significantly in effected and unaffected extremities on both groups. This shows that functional training methods like golf training may cause positive effect on neuromuscular system. Abdominal muscle strength was increased for each training group, because of the need to contract trunk muscles (Lim ve ark., 2002) during the golf swing. Short training period only increased trunk flexibility in both VGT and TGT group. Significant positive changes on anticipation reaction time in VGT group than TGT group shows the effects of necessity to follow concurrent visual feedback in virtual games. Our study shows that VGT and TGT programs which can be used as alternative therapy methods have positive effects on motor performance in children with cerebral palsy. POSSIBLE SELVES, PHYSICAL ACTIVITY, AND WELL-BEING IN OLDER ADULTS – A ONE YEAR LONGITUDINAL STUDY

HSU, Y., LU, J.H.

National Chiayi University

Abstract Model Possible selves, physical activity, and well-being in older adults – A one year longitudinal study Hsu, YW1, Lu, JH2 1: National Chiayi University (Chiayi, Taiwan), 2: Chinese Culture University (Taipei, Taiwan) Introduction "Possible selves" is an individual's self-knowledge about how he/she thinks of their own potential images in the future (Markus & Nurius, 1986). Literature suggests that possible selves is an important self-related construct for older adults' health behaviors and mental well-beings (Whaley & Schrider, 2005). However, literature recommended the vital need for empirical research in physical activity and exercise settings. The purpose of the present study was to examine the relationship among current self-views, future possible selves, physical activity participation, and well-being in older adults. Methods Longitudinal data was collected to construct a model illustrating the relationship among physical self-concept, possible selves, physical activity participation, and well-being. The potential moderators were also taken into account while examining the model. One hundred and eighty-seven community-dwelling older adults in Taiwan completed the survey packet three times every six months. Furthermore, semi-structured interviews were conducted to supplement the nature of older adults' possible selves on physical activity and exercise. Results In Time 1, 302 older adults finished the questionnaire. After one year, longitudinal data ($n = 187$) showed that older adults' future possible selves were influenced not only by their current self-views in baseline, but also by their health status, the disposition of hope, future time perspective, and the discrepancy of hoped-for and feared future selves. The interview indicated that: those older adults with regular exercise have more positive thought for the future, less worry over independence and live style in the future. Discussion The aim of this research was to extend the self-concept research in Taiwan through investigating older adults' possible selves in physical activity. The findings of one year longitudinal study illustrated the significance of using the construct of possible selves to understand older adults' physical activity exercise behaviors and psychological well-being. Furthermore, given that one's images of the future represent the most vulnerable and mutable component of the self (Whaley & Schroyer, 2010), the model in the present study and the moderators could serve as an effective roadmap to promote older adults' participation in exercise and physical activity. Finally, the supplemental interview showed that volunteering could be a protective factor while facing identity loss as ageing and is worthy of future investigation. (2005). *The Sport Psychologist*, 19, 148-164. Whaley, D. E., & Schroyer, R. (2010). *Journal of Sport Psychology in Action*, 1(1), 25-32.

THE ASSOCIATIONS BETWEEN EXECUTIVE FUNCTIONS OF PLANNING AND PROBLEM SOLVING AND BALANCE IN OLDER ADULTS

YU, T.C., CHIANG, C.H., CHU, I.H.

Kaohsiung Medical University, Taiwan

The associations between executive functions of planning and problem solving and balance in older adults Introduction Executive functions were shown to decline with age and seem to influence balance in older adults (van Iersel et al., 2008). The ability of planning and problem solving may play a role in this mechanism. Yet, the associations between these executive functions and balance in older adults

were unclear. Thus, the purpose of this study was to examine the relationships between executive functions of planning and problem solving and balance in older adults. Methods A total of 27 older adults (mean age 64.85 ± 2.71 yrs) were recruited for this study. Participants' dynamic balance was assessed using the "Timed Up and Go" test. Proprioception, a mechanism needed for balance, was measured using an ankle proprioception measuring instrument designed by professor Lan-Yuen Guo. The executive functions of planning and problem solving were assessed using a Tower of London Task. Pearson correlation analysis was used to examine the relationships between the recorded time (seconds) of the Timed Up and Go test and the angles (degrees) of the ankle proprioception test and the performance of the Tower of London Task. Results The results showed that there were no significant correlations between the recorded time of the Timed Up and Go test and total initial time ($r = 0.058$, $p = 0.779$), total executive time ($r = 0.069$, $p = 0.733$), and total time ($r = 0.123$, $p = 0.520$) of the Tower of London Task. There were also no significant correlations between the Timed Up and Go test and total move score ($r = 0.205$, $p = 0.315$) and total correct score ($r = -0.061$, $p = 0.767$). As for proprioception, there were no significant correlations between both active and passive proprioception of ankle dorsi flexion, plantar flexion, inversion and eversion and all measures of the Tower of London Task. Discussion The results of this preliminary study suggested that the executive functions of planning and problem solving were not associated with dynamic balance and ankle proprioception in older adults. Future studies with larger sample sizes are needed to further examine the relationships between these executive functions and balance in this population. ASSESSING STEREOTYPES ABOUT EXERCISE AMONG PEOPLE LIVING WITH HIV: DEVELOPMENT AND PSYCHOMETRIC EVALUATION OF THE HIV EXERCISE STEREOTYPES SCALE

DARRIPE-LONGUEVILLE, F., FALZON, C., BERGAMASCHI, A., SCHUFT, L., DURANT, J., ROSENTHAL, E., PRADIER, C., DURACINSKY, M., ROUANET, I., COLSON, S.S., GRAY, L.

University of Nice Sophia Antipolis

Introduction Despite the extensive literature related to the benefits of exercise in people living with HIV (PLHIV), a large proportion of this population is not sufficiently active according to current recommendations (O'Brien et al., 2010). Exercise stereotypes have been shown to be psychological barriers to exercise in specific populations (Emile et al., 2014; Falzon et al., 2014). The main objective of the current study was to validate a French-language scale measuring exercise stereotypes in PLHIV, in order to gain visibility to the possible barriers and facilitators for exercise. Methods A series of four complementary studies was carried out with a total sample of 524 participants (107 healthy individuals; 417 PLHIV) to: (a) develop a preliminary version of the HIV Exercise Stereotype Scale (HIVESS), (b) confirm the factorial structure, (c) evaluate the temporal stability, and (d) examine the construct validity of the instrument. Results Factorial analyses provided support for a 14-item scale with three subscales related to (a) stereotypes related to exercise benefits (e.g., "Physical activity improves the morale of HIV-infected people"), (b) stereotypes related to exercise risks (e.g., "Practicing a physical activity should be avoided by HIV-infected people because it causes injuries") and, (c) stereotypes related to the lack of capacity for exercise (e.g., "HIV-infected people do not have enough physical resources to practice a physical activity"). The scale indicated good internal consistency and stable test-retest reliability. Negative stereotypes related to exercise risks and the lack of capacity for exercise were inversely related to exercise self-efficacy and level of physical activity. Lastly, healthy individuals scored higher for both negative exercise stereotypes subscales. Discussion Although several scales have been developed to measure psychological constructs in PLHIV (Barroso & Lynn, 2002), the HIVESS is the first scale to record exercise stereotypes in this population. This scale presented satisfactory psychometric properties and constitutes a reliable and valid instrument for future research and clinical practice among French PLHIV. The procedure reported in this paper is however limited by the sociodemographic characteristics of the sample. Furthermore, the HIVESS, which was first developed in French, would need to be translated and validated in other languages in order to be used internationally. References Barroso J, & Lynn MR. MECHANISMS OF EXERCISE STEREOTYPES IN PEOPLE LIVING WITH HIV: THE MEDIATING ROLE OF PERCEIVED PHYSICAL FATIGUE AND SELF-EFFICACY

GRAY, L., FALZON, C., BERGAMASCHI, A., SCHUFT, L., DURANT, J., ROSENTHAL, E., PRADIER, C., DURACINSKY, M., ROUANET, I., COLSON, S.S., D'ARRIPE-LONGUEVILLE, F.

University of Nice Sophia Antipolis

Introduction Perceived physical fatigue is one of the most distinctive symptoms in People Living with HIV (PLHIV) (Lee et al., 2005). Exercise benefits for PLHIV are well documented (O'Brien et al., 2010), however a majority of PLHIV remains insufficiently active (Frantz & Murenzi, 2013). According to the stereotype embodiment theory (SET) (Levy, 2009), stereotype internalization influences health behaviors through self-perceptions. In line with this theory, exercise stereotypes have been identified as barriers to physical activity (PA) in specific populations (e.g., Emile et al., 2014). Furthermore, Emile et al. (2015) suggested that stereotypes may affect health-related outcomes through other processes than those related to internalization and notably through ego depletion effects. In this study, we considered the internalization and ego depletion pathways simultaneously by examining the mediating role of exercise self-efficacy and perceived physical fatigue in the relation between exercise stereotypes and PA in PLHIV. Methods A total of 560 PLHIV completed questionnaires measuring HIV exercise stereotypes (d'Arripe-Longueville et al., 2016), PA level (Robert et al., 2004), perceived physical fatigue (Fisk et al., 1994), exercise self-efficacy (Schwarzer et al., 2011), and stages of change for regular exercise (Prochaska et al., 1992). Results Analyses revealed a significant mediating effect of perceived physical fatigue between positive exercise stereotypes (i.e., exercise benefits) and PA level, and a significant mediating effect of exercise self-efficacy between exercise benefits and stage of change. There was no significant mediating effect between negative exercise stereotypes and PA level or stage of change. Exercise benefits were directly related to PA level. No direct effects were observed between negative stereotypes and PA level or stage of change. Discussion Exercise benefits were significantly related to PA level both directly and through the mediating role of perceived physical fatigue. This is in line with previous studies suggesting that positive exercise stereotypes encourage an active lifestyle (Emile et al., 2015) providing support to the ego depletion theoretical position. A significant mediating effect of exercise self-efficacy was observed between exercise benefits and stage of change, consistent with the SET and existing literature about the effects of stereotypes on PA through self-perceptions (Emile et al., 2014). Results provide support for multiple pathways of influence of positive exercise stereotypes in PLHIV and suggest some form of resistance to the internalization of exercise stereotypes.

zation of negative exercise stereotypes. Further research is needed to test this hypothesis. References Emile M., d'Arripe-Longueville F., Amato M., Cheval B., & Chalabaev A. SPORTSPECIFIC RISK FACTORS FOR DISORDERED EATING HABITS IN ELITE ENDURENCE SPORTS

KNOPF, T., MICHLMAYR, F.

university of applied science Wiener Neustadt

SPORTSPECIFIC RISK FACTORS FOR DISORDERED EATING HABITS IN ELITE ENDURENCE SPORTS Introduction Endurance sports is given as leanness sports and require athletes to have a low body weight to achieve high performance. Therefore elite athletes are at higher risk for disorderd eating or eating disorders (Dosil, 2008). The aim of this study is to identify potential sportsspecific risk factors related to eating habits of elite female athletes in triathlon and swimming. Furthermore the current paper addresses the research question if elite swimmers or triathletes are at a different risk of maybe struggling with eating patterns. Methods Regarding methodology section this study follows a qualitative social research including guided interviews. The respondents were asked to answer 39 questions, as for example: "Do you talk with your training-group about your weight?" or "Do you think there is a relationship between performance, weight and success in your sport?" All interviews were acoustically recorded and transcribed. The analysis of the interviews was done based on an analysis of content (Mayring, 2008). The sample of this study includes 12 female elite-athletes, 6 swimmers and 6 triathletes, who competed at the Olympic Games, World or European Championships and therefore are seen as experts in their sport. Results The results indicate that adolescence and the coach are the most named factors for changing eating habits in both sports. The coach is an important factor because coaches are having a big influence on athletes. Swimmers and triathletes describe their eating habits as healthy and important to reach better performances. Furthermore triathletes describe the demands of their sport as a factor for changing eating habits to lose weight. Specially the running part requires a low body weight. The respondent swimmers believe that swimming is a non-leanness sport and swimming is no risk factor for disorderd eating or eating disorders. Discussion The explore risk factors could lead athletes to change their eating habits which could be the beginning of disordered eating and furthermore eating disorder. Triathletes could have a bigger risk in comparison to swimmers caused by low body weight required for fastest running. Against common literature (Thompson & Sherman, 2010) respondents believe swimmers will become more corpulent in future and swimming should not be called leanness sport. The present thesis suggests that further research about eating habits and risk factors for disordered eating has to be done in triathlon. Triathlon consists out of three leanness sports and is not enough explored yet how the three sports influence each other. References Dosil, J. (2008). *Eating Disorders in Athletes*. ATTENUATION OF OSCILLATORY ALPHA ACTIVITY DURING WORKING MEMORY MAINTENANCE IN CHILDREN WITH POOR MOTOR COORDINATION

LIN, J.T., SUN, J.C.Y., WANG, C.H., TSAI, C.L.

National Cheng Kung University

Introduction Recent research has indicated that neuropsychological disorders and soft neurological signs might be related to motor proficiency problems in children with motor-related disorders. The neural mechanism underlying such problems in children, however, has thus far remained elusive. Methods Here we compared oscillatory EEG activity from 20 children with motor difficulties as defined by the movement Assessment Battery for Children – second edition (MABC-2) (aged 10 – 11 years; female =10; scores < 15th on MABC-2 test) and 20 age-and gender-matched typically developing counterparts (TD) (aged 10 – 11 years; scores > 25th on MABC-2 test) when they performed a visuo-spatial attention and working memory task. Results The results revealed that, relative to TD children, those with motor problems showed worse performance selectively in the working memory condition. This coincided with diminished ability in modulating neural oscillations, as evidenced by less posterior parietal alpha (8 – 13 Hz) suppression during late maintenance phase in these children. Importantly, we observed that such oscillatory alpha activity was significantly correlated with visuo-spatial working memory (VSWM) performance. Discussion These findings suggest that children with poor motor coordination might have a reduced ability to temporally maintain visuo-spatial information, resulting in poorer behavioral performance. We would thus conclude that changes in oscillatory EEG activity reflect some of the problems leading to cognitive deficits in children with poor motor coordination.

THE EFFECT OF MINDFULNESS MEDITATION AS A CLINICAL INTERVENTION TO REDUCE PAIN AND PSYCHOLOGICAL DISORDERS FOR INJURED ATHLETES

MOHAMMED, W.

University of Kent

Introduction Reesse et al, (2012) and Heaney (2006), mentioned that when athletes become injured there are numerous negative psychological changes including mood, decreased self-esteem, loss of identity and isolation. As a result sport injuries lead to worsening consequences in athletes' health. The aim of this research is to investigate the role of mindfulness meditation in assisting injured athletes in reducing the perception of pain and mood. Mindfulness can be defined as the awareness that emerges through paying attention in a particular way, on purpose, in the present and nonjudgmentally Zinn, (1994). Methods Independent variables: Group (Mindfulness-based Stress Reduction [MBSR], control) and Time (pre, post). Dependent variables: pain perception (of the injury) and pain tolerance (time to remove the hand in the cold pressor test). Both groups followed their normal physiotherapy treatment, but in addition the MBSR group practiced meditation for 8 weeks (one 30 minute session/week). Each week additional measures were: Mindfulness Attention Awareness Scale-MAAS, Profile of Mood State-POMS, Depression, Anxiety and Stress scale-DASS. Results Changes in mean pain perception scores showed no differences between the two groups ($p=0.242$), however, there was greater variability in pain perception scores after MBSR ($p=.01$). Pain tolerance showed a significant interaction between Group and Time with greater pain tolerance in the MBSR group after meditation ($F(1,12) = 12.453, p= 0.004$). MAAS scores increased over the 8 weeks and in addition increased after MBSR. POMS and DASS scores showed a decrease in all mood scores over the 8 weeks. Discussion MBSR has two effects on pain. First, an increase in pain tolerance indicating either less sensitivity/habituation to pain. This supports previous research that indicates the self-regulation benefits of MBSR on pain management and well-being (Nehra et al. 2012; Lykins & Baer, 2009). Second, an increase in the variability of the percep-

tion of pain to their injury. This indicates that MBSR can increase as well as decrease pain perception. Further research is required to determine the cause and could support other research that finds limited evidence for effectiveness of Mindfulness-based interventions for patients with chronic pain (Bawa, 2015). PREDICTING MENTAL TOUGHNESS IN TENNIS: THE ROLE OF SELF-AWARENESS

COWDEN, R.G.

North West University

Introduction Researchers have theoretically proposed (Loehr, 1995) or qualitatively found (Gucciardi, Gordon, & Dimmock, 2009) that self-awareness promotes mental toughness development or outcomes. To provide quantitative support for these suppositions and preliminary findings, this study examined the relationship between dimensions of self-awareness and mental toughness among competitive tennis players. Methods A sample of 333 male (N = 175) and female (N = 158) South African tennis athletes ($M_{age} = 29.24$, $SD = 13.95$) completed the Sport Mental Toughness Questionnaire (Sheard, Golby, & van Wersch, 2009) and Self-Reflection and Insight Scale (Grant, Franklin, & Langford, 2002) to assess mental toughness (i.e., confidence, constancy, control) and self-awareness (i.e., self-reflection, self-insight) dimensions, respectively. Multivariate multiple regression was computed to determine the extent to which the self-reflection and self-insight scales simultaneously predicted the mental toughness components of confidence, constancy, and control. Results Self-reflection, $F(3, 323) = 11.84$, $p < .001$, Wilk's $\lambda = .90$, partial $\eta^2 = .10$, and self-insight, $F(3, 323) = 33.36$, $p < .001$, Wilk's $\lambda = .76$, partial $\eta^2 = .24$, were both significant predictors of each mental toughness component. Compared to the mental toughness dimensions predicted by self-reflection [confidence, $F(1, 325) = 8.11$, $p = .005$, partial $\eta^2 = .02$; constancy, $F(1, 325) = 10.86$, $p = .001$, partial $\eta^2 = .03$; control, $F(1, 325) = 12.90$, $p < .001$, partial $\eta^2 = .04$], however, the effect size estimates were larger for self-insight [confidence, $F(1, 325) = 37.00$, $p < .001$, partial $\eta^2 = .10$; constancy, $F(1, 325) = 39.65$, $p < .001$, partial $\eta^2 = .11$; control, $F(1, 325) = 69.44$, $p < .001$, partial $\eta^2 = .18$]. Discussion Extending prior qualitative research, the results support the relevance of self-reflection and insight, as indicators of self-awareness, to the mental toughness of competitive tennis athletes. Although self-insight appears to be the most prominent factor to consider in relation to mental toughness, there are a number of prospective self-reflection and insight implications for tennis players' mental toughness, including psychological interventions aimed at reflective practices and cognitive reframing. PHYSICAL EXERCISE PERFORMED IN SIMULATED ALTITUDE CONDITIONS IMPROVES DECISION-MAKING

MELLO, M., AQUINO-LEMOS, V., DOS SANTOS, R.V.T., BITTAR, I.G.L., ANTUNES, H.K.M., LIRA, F.S., TUFIK, S.

Federal University of Minas Gerais; Federal University of São Paulo

Introduction Exposure to high altitude can worsen decision-making, whereas, it is known that physical exercise performed at sea level can improve cognitive functions, including decision-making. Taking this into account, the aim of this study was to evaluate the influence of acute physical exercise in simulated altitude conditions on decision-making performance. Methods Thirty-eight healthy men were included in the study, distributed randomly into four groups: Sea Level n=10, Simulated Altitude n=10, Exercise at Sea Level n=10 and Exercise in Simulated Altitude n=10. The values of mean \pm (SD) were age: 23 \pm (8) years, weight: 71 \pm (7) kg, height: 1.76 \pm (1) m, BMI: 22 \pm (9) kg/m² and Vo2 peak: 47 \pm (4) ml/kg/min. Decision-making was assessed using the Game of Dice Task (Rzezak et al., 2012), applied on the first day in all groups and reapplied on the second day, immediately after the exercise session of 60 minutes at 50% of Vo2 peak. The groups that were exposed to simulated altitude conditions equivalent to 4500-m remained in a Colorado Altitude Training™/12 CAT-Air Unit for 29 hours. Two-way ANOVA was used to determine differences between groups. The statistical significance was determined as $p < 0.05$. Results There was a significant improvement in decision-making ($p = 0.001$) in the exercise in simulated altitude group when compared with the simulated altitude group. In the simulated altitude group a significant worsening in decision-making ($p = 0.002$) was observed, compared with the sea level group. The exercise at sea level group presented a significant improvement in decision-making ($p = 0.006$) when compared with the sea level group. Discussion Our results show that acute physical exercise performed in simulated altitude conditions improves decision-making performance. This improvement can be explained by an increase in brain metabolism which may have influenced the increase in cerebral blood flow (Querido et al., 2007), improving decision-making (Gligoroska et al., 2012). Thus, we suggest that acute physical exercise may be a strategy for minimizing impairment in decision-making in people travelling to high altitudes. References Gligoroska JP, Manchevska S. (2012). CAPACITY LIMITS OF TRACKING MULTIPLE MOVING OBJECTS IN ELITE BASEBALL AND SOFTBALL PLAYERS

WU, S.K., CHIANG, C.H., YANG, H.H., CHEN, W.Y.

National Taiwan University of Sport

Introduction: Playing a ball sport always involves tracking multiple moving targets. Baseball and softball players have to track the moving balls, the running teammates and opponents at the same time in order to have a best defense. An exceptional baseball or softball player might have a better performance of attentively tracking multiple moving targets than non-athletes. The purpose of the study was to examine this hypothesis. **Method:** Forty-nine male baseball, 25 female softball players, and 39 non-athletes (20 females and 19 males) were recruited in this study. The tracking performance for all participants were measured with the typical Multiple Object Tracking (MOT) Task (Pylyshyn & Storm, 1988). In this task, participants were asked to attentively track specific targets wandering around the computer monitor among some distractors for a few seconds, and they reported those targets in the end of trial. The study manipulated the object moving speeds for the Experiment 1 and manipulated the number of tracked targets for the Experiment 2 to measure the capacity limits of attentive tracking for athletes and non-athletes. **Results:** No matter how fast the targets moved in the Experiment 1 or how many targets were tracked in the Experiment 2, baseball players significantly performed better than non-athletes, and the tracking performance of softball players was non-significantly worse than baseball players and better than non-athletes. The capacity limits of attentive tracking were calculated with the speed limit for the Experiment 1 and the number limits for the Experiment 2. Baseball players performed significantly higher speed limits and larger number limits than non-athletes. This study suggested baseball players having significantly larger capacity limits of attentively tracking than non-athletes.

EXPERT-NOVICE DIFFERENCES IN SPORT-SPECIFIC CUEING ATTENTION: AN EVENT-RELATED POTENTIAL STUDY

WANG, C.H., SUN, J.C.Y., LIN, J.T., TSAI, Y.Y.

National Cheng Kung University

Introduction Athletes have been widely demonstrated to show superiority in sport-specific information processing. The neural mechanism that characterizes such expert behavior, however, has thus far elusive. Accordingly, we examined event-related potentials (ERPs) elicited during a cueing task involving sport-specific contexts to further address this issue. **Methods** We compared ERP measures associated with cueing attention (i.e., contingent negative variation, CNV) from male racket sport players ($n = 16$; aged 20.56 ± 1.82 years) and male novice controls ($n = 16$; aged 20.73 ± 1.50 years) when they performed the sport-specific cueing task in which racket-sports-related body movements were used to indicate the possible locations of a forthcoming target. **Results** The behavioral findings primarily showed that racket sport players responded faster to targets as compared to novice controls, regardless of cue types. Specifically, we observed that, relative to controls, players exhibited smaller CNV amplitudes at Fz and Cz electrodes, indicating that less attention resources were required for cueing attention in players. **Discussion** These findings suggest that cueing attention may be enhanced via long-term participation in racket sports training. In addition, the ERP results may point to optimal performance with minimal cortical resource consumption when processing sport-specific cues in the players, further supporting the neural efficiency hypothesis in athletes. We thus conclude that the training-induced enhancement in perceptual-cognitive processes (e.g., cueing attention) may contribute to greater efficiency in neural processing.

ON THE EFFECTIVENESS OF COUNSELING APPROACHES FOR ENHANCING ATHLETIC PERFORMANCE

NAKAGOMI, S.

University of Tsukuba

Introduction Standard mental training for athletes mainly involves teaching psychological skills without directly dealing with the athlete's personality development. The present author, however, believes that counseling and or psychotherapeutic techniques can be effective not only for personality development but also for enhancing athletic performance. The author has been applying these techniques in his daily practice of psychological support for athletes. In mental training seminars, the author uses a mental training program in which psychotherapeutic techniques are applied together with a few standard psychological skill exercises (Nakagomi, et al., 2006). The present study examines the effectiveness of the counseling techniques for enhancing athletic performance. **Methods** With reference to the author's own consultation cases in which counseling approaches resulted in performance enhancement, the author attempts to elucidate the factors leading to effective counseling. **Results and discussion** The author could identify five characteristics of effective counseling. (1) "Free and protective spaces" in counseling rooms promote self-expression and stimulate the flow of psychological energy in client athletes. (2) Talking about their athletic behavior in front of their counselor helps clarify their problems in relation to competition, and helps create their understandings of and meanings regarding their athletic behavior. (3) Athletes who talk frequently about their bodies and body movements experience a type of image training. (4) The increase in their awareness and intention through counseling will change their athletic attitude and the quality of their training. (5) Psychological problems are recognized in the background of their many performance problems, and thus those problems are treated and resolved through counseling. All five characteristics do not necessarily appear in each successful case, though at least one is always involved. Successive sessions for athletes will change the relative importance of psychological support from teaching psychological skills to counseling, and from then on almost all the sessions will exclusively consist of counseling (Hiraki T. & Nakagomi S., 2009). **References** Hiraki T. and Nakagomi S.(2009) Cooperation between mental training and counseling: A case study of one psychological support involving a shift from mental training to counseling. PERCEPTION-ACTION COUPLING AND EXPERTISE IN A TRACKING TASK

MALLEK, M., THOUVARECQ, R., BENGUIGUI, N.

University of Caen Normandy

Introduction Interceptive actions in sports requires prodigiously and accurate visuomotor coordination (Le Runigo et al., 2010). Consequently, it can be assumed that expertise in such sports can be identified in the ability to couple with accuracy perception and action. In this context, the purpose of this study was to show that expert perception-action coupling can be revealed in an experimental visual-motor tracking (VMT) task if the constraints of this later are high enough for sensory-motor control. **Methods** Three study groups were tested corresponding to their expertise in tennis. The Super-Experts(SE; International level; n=13); Experts(E; National-Regional level; n=14) and

Non-Experts (NE; n=13). Subjects were asked to track a moving ball on a screen with a stylus. The ball could bounce on the side of a square and could have two different accelerations (A0: 0 m/s²; A1: 0.05 m/s²). We divided each trial in two periods: bounce tracking (BT: tracking at the vicinity of the bounce) and free tracking (FT: tracking without bouncing effect). Then for each period, we analysed temporal variables: reaction time (RT); duration of BT period and kinematic variables: distance to target (DT), Alpha Mean (AM: mean angle between to the ball direction and the cursor direction), average occurrence of DT reducing gaps (DTRG: number of times where participants reduced the distance cursor-target) and average occurrence of AM reducing gaps (AMRG: number of times where participants reduced the angle cursor-target). All data were assessed using an Expertise (SE vs. E vs. NE) x Acceleration (A0 vs. A1) x Tracking period (BT vs. FT) analysis ANOVA with mixed-design. A forward stepwise regression with duration of BT period and AMRG as predictors were calculated to evaluated the origin of performance of AM and DT. Results Analysis of DT and AM variables showed a significant main effect for Expertise, Acceleration, and Tracking period. NE demonstrated a greater AM and a longer DT than E and SE ($p < .05$). For temporal variables (RT and BT period), a significant main effect was showed for Expertise and Acceleration. For both indicators of regulation (DTRG and AMRG) a significant effect of Expertise and Tracking period was revealed. NS had a smaller DTRG and AMRG than and SE ($p < 0.05$). The analysis of regression with BT period and AMRG as predictors and AM as dependent variable revealed a significant correlation with $r = 0.78$. Discussion As expected, the VMT task discriminate expertise, particularly in the most constraining conditions (BT period and A1 condition). BT duration and AMRG variables differentiate expertise and predict performance in VMT task. This suggests transferable information-movement coupling capacities in this task and that perception-action adaptations can be determinant factors of expertise (Le Runigo et al., 2010). References Le Runigo, C., Benguigui, N., & Bardy, B. G. (2010). Visuo-Motor Delay, Information-Movement Coupling and Expertise in Ball Sport. Journal of Sports Sciences. 28, 327-337. TRAINING OF ATTENTION IN SPORTS USING HEMOENCEPHALOGRAPHY

STUCKE, C.1, LANGNER, S.1, WOLFGRAM, H.J.2

1: Otto von Guericke University (Germany), 2: MediTECH (Germany)

Introduction Attention is a key factor in optimal athletic peak performance and necessary when action control is required. According to Norman and Shallice (1986), the supervisory attentional system (SAS) controls non-routine procedures. Under specific conditions concentration may inhibit peak performance. In such cases automated routines regulated by contention scheduling mechanism are essential to success. This leads to diverse attention patterns depending on movement phases. Our goal is to investigate if near-infrared based HEG (Toomim, 2002) might be an effective method to analyze and train particular attention pattern during various movements. Methods The non-invasive HEG monitors hemodynamic activities in the prefrontal cortex (PFC) by detecting changes of blood oxygenation. Hence describes neuronal activity in PFC (Serra-Sala et al., 2012), which is a particularly important part of the brain to control executive functions such as attention. We used an HEG-system provided by MediTECH company to examine following: (1) Evaluation of reliability of HEG-plots during 7 different movements and conditions (91 athletes) and (2) development of individual HEG-feedback-program with sport specific video sequences. Results The results of our researches have shown individual task-related HEG-plots. During acyclic movements we detected individual differences in the plots. These are reproducible under similar conditions ($rtt=.804-.893$). Attention patterns depend on movement phases, training conditions and situations. Our prototype to demonstrate HEG-feedback program is based on typical pattern of a high performance level in trapshooting. In 14 HEG-feedback-sessions the athlete practiced a movement-related attentional behavior. During feedback session HEG-plots have been optimized and resulted in significant improvement of shooting scores. Additional, we found individual differences during cyclic movement in the HEG-plots, especially in the higher loading increments during ergometry. The reproducibility of the plots was possible ($rtt=.97$) but patterns were depending on mental strategies. Discussion HEG is an analytical measure and feedback option which can be easily applied. The results indicate that athletes can practice a movement-related attention behavior effectively by using HEG-feedback. It helps to toggle between non-routine procedure and subconscious processes. HEG feedback allows analyzing and shaping individual performance to optimize competition results. Further improvements of the program may be attained by simultaneous measurement of HEG and physiological / biomechanical parameters. References Norman D, Shallice T (1986). Plenum, 4, 1-18. CAREER PATHS AND POSTRETIREMENT ADJUSTMENT AMONG SPANISH ELITE-ATHLETES

LÓPEZ DE SUBIJANA, C., BARRIOPEDRO, M., MUNIESA, C., GÓMEZ-RUANO, M.A.

TECHNICAL UNIVERSITY OF MADRID-INEF

The study presented by Pallarés, Azocar, Torregrosa, Selva, and Ramis (2011) proposed three types of sport career paths: i) linear: where the athlete gives exclusive dedication to sport; ii) convergent: in which the athlete prioritises the sport career but he/she maintains another activity (i.e., study or work); and iii) parallel: where the athlete places equal importance on the sport career and the alternative activity. Particularly, the available research has been focused on how athletes who follow a "dual career" (DC) are less likely to suffer difficulties regarding their social and labor market integration after their sport career (Tekav, Wylleman, & Cecir Erpic, 2015). Thus, the aims of the present study were to analyze whether the type of career path chosen is related to: i) their academic level, ii) the labor market integration; and iii) the difficulties experienced after the retirement. Methods An adaptation of the Athlete's Retirement Questionnaire (Alfermann, Stambulova & Zemaityte, 2004) was fulfilled by 178 retired athletes (n= 109 male and n= 69 female; 39±7 years). Results Most of the athletes combined the studies and sport while they were at the mastery stage of their sport career, in the convergent (40.1%) or in the parallel (30.5%) way. Only 15.3% of the athletes were focused solely on the sport. The career path was not independent of the gender. More female than male combined studies and sport in a parallel way (39.1% vs. 25.0%) while more male than female followed a DC combined with their work (18.5% vs. 7.2%) or were focused solely on the sport (20.4% vs. 7.2%). Significant differences were found regarding the academic level reached according to the model chosen for male but not for female. The male athletes who followed a career path combining the studies and the sport in a convergent or in a parallel way reached a higher academic level than those who were focused solely on the sport and those who combined working and the sport. In addition, the results showed that 87.0% of the male and 89.9% of the female athletes were employed and no differences were found in the income level of the athletes according to the career path. Neither gender nor career path were related to the difficulties experienced after the retirement. The most important difficulties perceived by the athletes were the financial (2.35±1.43) and social-relationships problems (2.18±1.40). Conclusions The career path followed during the mastery stage does not make a difference in the quality of life after the sport career. The results point out that combining the sports with the studies ensures the achievement of higher education studies for male athletes. However, no income level differences were found after the sport retirement. References Alfermann D, Stambulova N, Zemaityte A. (2004). Phy of Sport and Exer 5 (1),

CAREER TRANSITIONS AND OCCUPATIONAL WELL-BEING OF WOMEN IN LEADERSHIP: THE CASE OF WOMEN AS SPORTS COACHES

DIDYMUS, F.F., NORMAN, L., HURST, M.

Leeds Beckett University

Introduction: The United Kingdom (U.K.) is working to develop the world's leading sports coaching system. However, women currently make up only 28% of the profession and very few reach senior levels. Little is known about why career pathways are gendered or how women coaches' occupational experiences affect their health and well-being. Therefore, the aim of this study was to further understanding of the occupational health and well-being of female sports coaches and to investigate the facilitators of and barriers to their career transitions. Method: Following institutional ethical approval, women coaches ($n = 162$) based in the U.K. volunteered to take part. Each coach completed an online version of A Shortened Stress Evaluation Tool (ASSET; Cartwright & Cooper, 2002). This questionnaire is a valid and reliable measure of job characteristics, organisational commitment, health, and psychological well-being. Descriptive statistics were computed using a Statistical Package for the Social Sciences to provide a broad overview of the data. Results: The preliminary analyses demonstrate that 97% of the sample categorised themselves as 'White', 'White Irish', or 'White Other'; that the number of respondents over the age of 55 ($n = 6$) was dramatically lower than the number of responses from younger coaches ($n = 156$); and that 67% of the sample was educated to undergraduate degree level or higher. Over half of the sample (53%) was employed as a head coach at the time of completion and 56% of these head coaches were employed on a part-time basis. When compared to the normative data for ASSET, our sample reported above average psychological well-being ($M = 27.75$, $SD = 4.87$), sense of purpose ($M = 18.72$, $SD = 4.01$), and engagement ($M = 19.18$, $SD = 3.78$), and reported less strain on their psychological health ($M = 21.06$, $SD = 6.91$). However, the results also demonstrate that the coaches experience poorer work-life balance ($M = 13.33$, $SD = 5.35$), job security ($M = 14.20$, $SD = 5.39$), and work relationships ($M = 18.02$, $SD = 7.88$) than the normative sample. Conclusions: The findings suggest that, on average, our sample of women coaches are highly engaged with their role, feel a sense of purpose during their coaching practice, and are psychologically well. The results do, however, suggest that women coaches require better work-life balance, more job security, and more meaningful relationships with their colleagues. These findings provide insight to potential facilitators of and barriers to career progression for women coaches and offer interesting applied implications for national governing bodies (NGBs). In particular, NGBs should pay acute attention to interventions that support women coaches to connect with other coaches and effectively balance their personal and occupational commitments. MO-SH03 Sport Statistics & Analysis: Team Sports

THE ACTIVITY PROFILE OF GERMAN ELITE FORWARDS WITH REGARD TO MATCH OUTCOME

CHMURA, P., KONEFAŁ, M., ANDRZEJEWSKI, M., KOWALCZUK, E., MROCZEK, D., MAĆKAŁA, K., KAWCZYŃSKI, A., ROKITA, A., CHMURA, J.

University School of Physical Education

Introduction Optimal physical preparation of elite players has become an inseparable part of professional soccer, especially with regard to the increasing physical demands of modern match-play (Yue et al. 2014). Tracking the performance of players in different positions on the pitch allows us to determine factors affecting a successful match outcome. The aim of the study was to determine the activity profile of soccer forwards with regard to match outcome. Methods Physical and technical match performance (PTMP) data were collected from 91 forwards from the German Bundesliga during the 2014/2015 domestic season. 516 individual match observations were made with regard to match outcome: won, drawn, loss. The analysis was carried out using the Impire AG motion analysis system (Tiendemann et al. 2011) with records of all PTMP of players in all 306 Bundesliga matches. 65 players' parameters recorded by the system were examined. Results In the won matches the forwards featured significantly higher ($p \leq 0.05$) measures of total covered distance in match-play and distances covered with intensities of 11-14 km/h, 21-24 km/h, and above 24 km/h than in the lost and drawn matches. Similar differences were found in the number and length of sprints and in mean running speed ($p \leq 0.01$). The match motion analysis showed that in won matches the forwards also attained a significantly higher number of ball touches ($p \leq 0.001$), % of accurate passes, and % of won one-on-one plays ($p \leq 0.05$) than in drawn and lost matches. Discussion The performance parameters of studied forwards' have a decisive impact on match outcome as their levels are much higher in matches won by the forwards' teams. If a notational analyst or a coach has identified that physical and technical aspects of players' performance are adversely influenced by match outcome, possible causes of this impact can be determined and match preparation can focus on reducing such effects (Nassis et al. 2015). Thus, researchers should include match outcome and playing positions in their explanatory models in order to better understand why physical demands vary throughout the game (Lago 2009). The outcome of a soccer match depends to a great extent on forwards' efficiency, and the results of the present study may be used for advancement of physical and technical preparations of forwards in soccer (Carling 2010). REVEALING PARAMETERS THAT INFLUENCE GAME FLOWS IN FOOTBALL USING JORDAN NETWORK

SAITO, Y., KIMURA, M., ISHIZAKI, S.

Shibaura Institute of Technology

INTRODUCTION Sometimes the change of game balance in football games is discussed based on the idea of game flows (Alister et al., 2005), however, the quantitative definition has not been clarified. The aim of this study is reveal features that influences game flow factor by constructing and analyzing the game flow models. **METHODS** We use play-action data and game flow data in this study. The play-action data include time series data such as coordination of the ball, the players who play the ball, the type of the play-actions, (e.g. pass, shoot and dribble) and so on. The game flow data are two dimensional vectors represented advantage of both home teams and away teams. Either zero or one are assigned to each element in the vector, for example, if the home team gains an advantage, and in contrast, the away team loses it, the vector becomes (1, 0) and vice versa. In order to construct the game flow models, we chose Jordan neural network. The Jordan network is a class of artificial neural networks whose inputs at the time include one of outputs at the time. Since, in football games, the game flows should be closely related to the prior situation, the Jordan network should be suitable to model game flows. We trained network using the play-action data that have over 900 parameters as the input and the game flow data as the output. Afterwards, we applied the sensitivity analysis to the game flow model and revealed parameters that contribute to the game flows. In our experiments, we constructed the game flow model using data of Urawa Reds' (a club of Japan Professional Football League (J-League)) five games and applied the model to other five games to predict their game flows. Moreover, we applied the sensitivity analysis to the game flow model. **RESULTS** We confirmed that the predicted game flows were well explained in the real game situations. This suggests that the constructed game flow model was relevant to predict game flows in Urawa Reds' games. Sensitivity analysis of the obtained neural network shows the frequencies of Makino and Moriwaki handling the ball in front court varying from 0 to 1 cause the large difference of the values of Urawa Reds game flow around 0.97. This shows Urawa Reds' superiority was influenced on whether Makino and Moriwaki, defenders in Urawa Reds, played at the higher position than other games or not. **DISCUSSION** The frequencies that Makino and Moriwaki played at the higher position precisely represent the frequencies that they contributed Urawa Reds' attacks. Urawa Reds is a team with the highest ball possession rate in J-League and it often makes attacks with many of the players. From these reasons, it was reasonable results that Makino's and Moriwaki's attacks influenced on Urawa Reds' game flow. **REFERENCE** Alistair H, Chris H, Andy C. (2005). Momentum in Soccer. THE ASSOCIATIONS OF SPIKING TYPES WITH TOTAL SCORES AND SCORING OF SERVE RECEIVE-TO-SPIKE IN VOLLEY-BALL GAMES: AN INVESTIGATION INTO THE FINAL EIGHT TEAMS IN 2015 ASIAN MEN'S CLUB VOLLEYBALL CHAMPIONS

HUANG, H., LIN, H., WU, M.

National Cheng Kung University, Dong Hwa University, Tunghai University

This study aimed to investigate the relationship across total scores, scoring of serve receive-to-spikes and spiking types in 2015 Asian men's volleyball club. In addition, we also interest in the question which spiking styles (i.e., spiking styles and spiking positions) are mostly related to scoring of spikes. We adopted the game performances of the top eight teams in 2015 Asian Men's Club Volleyball Championship for further analysis. We firstly described the recorded data and subsequently conducted Pearson product-moment correlations address this issue. The results revealed that (1) the positions of spiking styles varied according to the spiking areas. In terms of the front court, the greatest contribution can be attributable to the spiking at position 4 (44.87%), intermediate contribution for the position 3 (24.24%), and smallest contribution for the position 2 (24.24%). For the back court, the greatest contribution can be found for the spiking at the position 1 (8.77%), intermediate contribution for the position 6 (3.02%), and smallest contribution for the position 5 (0.09%). (2) The distribution of spiking types were that: for the front court, the most spiking type was the adjusted high ball spikes at the position 4 (19.72%), and then followed by flat spikes at the position 4 (16.08%), type A quick-set spikes (10.52%) at position 3, and high ball spikes in the position 4 (9.08%). For the back court, the most spiking style was high ball spikes at the position 1 (5.11%), and then followed by tipping spikes in the position 1 (3.66%), and flat spikes at the position 6 (3.02%). Importantly, the correlation analysis suggested that there were significant relations of tipping spiking at the position 1 to the serve receive-to-spikes as well as total spiking scores. Taken together, these results indicated that the major spiking styles for Asian men's volleyball were the position 4 for the front rows and position 1 for the back rows, separately. Furthermore, there were significant association of tipping spiking at the position 1 with the scores of serve receive-to-spikes and total scores. The above evidence suggests that an increase of spiking at the position 1 was mostly related to greater scoring in volleyball games. We thus concluded that, in 2015 Asian Men's Club Volleyball Championship, although the greatest contribution of scoring was the spiking at position 4, the success of winning games may be particularly related to the adoption of spiking strategy at the position 1.

TACKLE AND RUCK PERFORMANCE IN INTERNATIONAL RUGBY – SOUTHERN HEMISPHERE VS. NORTHERN HEMISPHERE

HENDRICKS, S.1,2, VAN NIEKERK, T.1, SIN, D.W.1, BROWN, J.1, MAREE, W.3, LAMBERT, M.1

1 University of Cape Town, Division of Exercise Science and Sports Medicine. 2 LeedsBeckett University, School of Sport, Carnegie Faculty. 3 South African Rugby Union

Introduction Rugby union is characterized by frequent contact situations known as the tackle and ruck, where opposing players compete for possession of the ball. Winning contact situations is an essential quality of successful teams. For players to win contact situations, players need to be technically proficient in their ability to execute contact techniques. The majority of contact technique research in rugby union relates to the tackle situation and conducted at the franchise level (for example, Super Rugby). Therefore, the first aim of this study was to investigate tackle and ruck contact performance at International level. At the International level, Southern Hemisphere teams seem to be more successful than Northern Hemisphere teams. However, there is limited work on the differences in contact performance between Southern Hemisphere and Northern Hemisphere teams. Therefore, the second aim of this study was to compare tackle and ruck contact performance between the major Southern Hemisphere and Northern Hemisphere International competitions. Methods A total of twenty-seven matches were analysed - 15 matches from the 2014 Championship competition and 12 from the 2014 Six Nations competition - this amounted to 4436 tackle contact situations. From the 4436 tackles, 2920 evolved into a ruck. Contact techniques for the tackle were described using descriptors such as tackle type, tackle direction and post tackle activity. Contact techniques for the ruck were described using descriptors such as the number of players at the ruck, ball placement and ruck activity. The association between the de-

scriptors and contact success (tackle break, offload, possession) was determined using multinomial logistic regression and reported as relative risk ratios (RRR). Results For type of tackle, tackling the ball-carrier by the jersey increases the chances of a tackle break occurring compared to using a shoulder tackle (RRR 2.76, 95% CI 1.40 – 5.41, $p \leq 0.01$). The defensive team was 66% more likely to win possession of the ball at the ruck when committing 3-5 players at the ruck (RRR 0.34, 95% CI 0.19 – 0.64, $p < 0.001$) compared to committing 0-2 players. Offloading after contact occurred more frequently in the Six Nations (20% vs. 12%, $n=4447$), whereas tackle breaks occurred more frequently in the Championship (17% vs. 11%, $n=4447$). Conclusion This study is the first study to describe both tackle and ruck contact techniques associated with success in International rugby. The tackle contact techniques associated with contact success are similar to those found in other studies. A distinction between the Championship and Six Nations emerged in how teams continued to play if a ruck is not formed.

EVALUATING THE QUALITY OF OPPONITION IN BASKETBALL GAMES BASED ON TOPSIS METHOD

SHAOJIANG, Z.1, HOUYOU, L.2, ALBERTO, L.3

1: INEF, UPM (SPAIN), 2: SCNU (CHINA), 3: INEF, UPM (SPAIN)

Introduction It is an important task to determine the strength of the opposition when assessing performance of basketball teams and players. The aim of this study is to develop an evaluation model to assess the offensive, defensive and overall quality of basketball teams based on the Technique for Order Preference by Similarity to the Ideal Solution (TOPSIS). Methods Data were collected from all 612 games played by the 18 participating teams in the 2013-2014 regular season of the Chinese professional basketball league. (i) Using the method of TOPSIS assesses the offensive ability, defensive ability and overall strength of the 18 teams based on 9 attacking-related variables, 4 defending-related variables and all variables together. (ii) Testing the reliability of the order estimated by TOPSIS. This step was achieved by testing the correlation coefficient between the TOPSIS-calculated rank of offensive ability, defensive ability and overall strength and the points scored, points against and final season rank. Results A very likely high correlation ($r = 0.62$; $\pm 90\%$ confidence interval: ± 0.26) was found between TOPSIS-ranked offensive quality and points scored by teams, and a likely moderate correlation ($r = 0.47$; ± 0.32) was tested between the TOPSIS-ranked defensive strength and point against of teams. While there was also a very likely high relationship ($r = 0.57$; ± 0.29) between the end-of-season ranking and TOPSIS-calculated ranking. Discussion Existing studies about the determination of quality of opposition mainly depend on the end-of-season classification, either using a symmetric division or employing a cluster analysis procedure (Gomez, et al., 2013). However, the objectivity of these ways has been doubted, and a more scientific systematic solution is called for (Dadelo et al., 2014). Results of our study demonstrates that TOPSIS method can be regarded as an effective method for assessing the quality of basketball teams (Chen et al., 2014), especially for evaluating offensive ability and overall strength of teams. However, the effectiveness when using this method to evaluate the defensive ability is not ideal, which may be caused by the reliability of the defensive variables (Liu et al., 2013) References Chen C C, Lee Y T, Tsai C M. THE ANALYSIS OF WINNING PERCENTAGES AND STRENGTHS DURING TOKYO BIG6 BASEBALL LEAGUE

TORIUMI, T., WATADA, H.

Keio University

Introduction Tokyo Big6 Baseball League is one of the most famous intercollegiate baseball leagues that features six prominent universities in the Tokyo area. All games are played at the same stadium in Tokyo. The six teams play short seasons in the spring and autumn of each year. Each team plays a short series against each of the five other teams in the league. The series format is similar to a three-game playoff, where the first to two wins is given one point. When a team wins the first two games, the third game is not played. In the case of a tie game, there is a rematch in the next day. The champion of the league is determined by the team with the highest points. When some teams have the same highest point, the champion is determined by the team with a highest winning percentage. When some teams have the same highest point and winning percentage, the champion is determined by a playoff after the end of all the league games. There is a possibility that a team falls to second in the standings despite having the highest winning percentage. The aim of this study was to analyze the results with Bradley-Terry model for paired comparison data (Agresti, 2002) and to compare the strengths of the teams between the highest points and the highest percentage. Methods We considered 140 seasons of the Tokyo Big6 Baseball League since 1946. First, we calculated the winning percentages of the 1st and 2nd teams in the standings of each season. Second, we sorted up the seasons of which a team fell to 2nd in the standings despite having the highest winning percentage. Third, in order to estimate strengths of the teams by analyzing the outcomes of each season, we conducted the Bradley-Terry model. We didn't consider home advantages and ties. Results There were six seasons of which a team fell to 2nd in the standings despite having the highest winning percentage. In the spring in 1949, the set of winning percentages and strengths (set to zero for the first team) of 1st and 2nd teams from the Bradley-Terry model are respectively (60.0%, 0 and 61.5%, 0.409). In the autumn in 1955, (76.9%, 0 and 81.8%, 0.300); in the spring in 1961, (76.9%, 0 and 81.8%, 0.502); in the spring in 1968, (76.9%, 0 and 81.8%, 0.317); in the autumn in 2009, (61.5%, 0 and 66.7%, -0.01); in the spring in 2013, (71.4%, 0 and 81.8%, -0.178), respectively. Discussion In every six seasons we found three facts. First, without the matches between the 1st and the 2nd team, both teams had the same points (three or four). Second, in such cases, the winning percentage of the 2nd team were higher than that of the 1st team. Third, at the matches between the 1st and the 2nd team, the 1st team won against the 2nd team with two wins and one loss. From the result and three facts, the result of the third match between the 1st and the 2nd team may decide the champion regardless of the winning percentage and the strength derived from Bradley-Terry model. PHYSICAL DEMANDS OF MATCH-PLAY IN ELITE ULTIMATE

DI MICHELE, R., OMETTO, C.

University of Bologna

Introduction Ultimate is an increasingly popular sport, played on a 100 x 37 m grass pitch by two teams of 7 players, whose aim is to score points by passing a 175-g plastic disc (known as Frisbee) to a teammate in the opposite 18-m long end zone of the field (Baccarini & Booth, 2008). Despite Ultimate being played worldwide at high competitive levels since some decades, only recently there has been

some attention to the physical demands of this sport (Krustrup & Mohr, 2015). However, no data are still available from matches played at high competitive level. Therefore, this study aimed to assess a selection of physical performance parameters assessed during competitive match in elite Ultimate players. Methods Twelve male players (age: 23 (5) years; body mass: 68 (8) kg; stature: 175 (9) cm), belonging to three elite teams participating to an international Ultimate tournament were involved. Their playing position was handler (n=4), and cutter (n=8). The players were equipped with a GPS device during a selection of matches played during the examined tournament. The following indices were measured: total distance covered, average speed, number of sprints, and average sprint length. Since the number of points played in a match is highly variable between players, point averages were considered for the analysis. For all parameters, the mean is presented with the 95% confidence interval. Results For handlers, observed averages per point for total distance covered, average speed, number of sprints, and sprint length, were, respectively: 178 (147-208) m, 7.7 (7.1-8.3) km/h, 5 (4-6), and 12.9 (11.2 to 14.7) m. For cutters, the same variables showed the following values: 200 (170-230) m, 8.8 (8.2-9.4) km/h, 6 (5-7), and 16.6 (14.9-18.3) m. Discussion The present findings reveal that the physical effort in Ultimate is characterised by several short repeated sprints, interspersed by rather long recovery times. Moreover, the physical demand seems to be rather affected by the playing position, with cutters showing overall higher running speeds and distances covered. These results provide coaches with relevant information for physical conditioning of elite Ultimate players. Specifically, repeated-sprint ability would seem a key physical capacity for the performance in this sport. Future studies are warranted to assess how the number of points played per game by each player, and the number of games per tournament, affect the physical demands in Ultimate. INFORMATION ENTROPY IN THE EVALUATION OF MOVEMENT VARIABILITY IN BASKETBALL SHOOTING

CHIANG, H.Y., HSIEH, T.Y., LIU, Y.T.

National Experimental High School at Hsinchu Science Park

Introduction The considerable redundancy of the human system leads to the variability in repetitive attempts to accomplish the task demand and its performances usually deviated from normal distribution (Newell et al., 1984). The concept of information entropy (IE) is developed from the information theory of communication where high information entropy is parallel to high levels of variability. Previous studies showed that the IE of movement trajectories decreased when the movement was close to the target in aiming task (e.g., Lai et al., 2005). Nevertheless, most of the previous research that applied IE only to the simple movement task. The purpose of this study was to analyze the movement variability of the multi-joint movement (basketball shooting) using information entropy. Methods The Phase-space system (480 Hz), and two JVC cameras (30 Hz) were used for the experimental setup. Seven participants performed 500 jump shots and only the successful shots were analyzed. Kinematics data of six joints (ankle, A; knee, K; hip, H; shoulder, S; elbow, E and wrist, W) were captured and the shooting movement (from the maximum velocity of the hip to the moment of ball release) was separated equally into 10 phases (10 % of normalized time) for IE calculation. The IE was calculated by the probabilities of the actual frequency distribution for the 10 phases within each joint in movement trajectory. Repeated measure ANOVAs were used to compare IE on 10 phases in different joints. Results The shooting average of 76.5% demonstrated the high basketball skill levels of the participants. Four of the six joints maintained relatively high IEs without any noticeable trend over the 10 phases. The IE of W and E shared another pattern where the minimum IE occurred at middle phases ($p < .05$) and followed by an abrupt increase of IE until right before ball release. At the last phase of ball release, the IE of W and E dropped significantly ($p < .05$). Discussion During the jump shot movement, the forearm that was holding the ball had a moment of pause before the final extension. The pause of the forearm movement led to the decrease of the IEs observed in the elbow and wrist joints around the middle phases. As soon as the forearm extended again after the pause, the IEs from the elbow and wrist joints quickly caught up with IE of the other 4 joints. At the last phase where the ball was released from the hand, IE of most joints had a decreasing trend due to reduced movement of these joints. The change of IEs over the different phases of jump shot movement seems to directly relate to the range of movement. Future studies should compare the IE with different groups (e.g., unskilled player) and also take into account of the individual differences. RELIABILITY AND VALIDITY OF TECHNICAL INDICATORS IN THE ULTIMATE FRISBEE

RUSSOMANNO, T.G., COSTA, F.R., SCREMIN, I., EUZEBIO, M.V., SARTORIO, G., MONEZI, L.A., BURATO, M.A.B., SILVA, B.S., MERCADANTE, L.A.

UnB Universidade de Brasilia

Introduction Ultimate Frisbee is a young team sport compared to other sports like soccer and rugby. The main difference is that the ultimate Frisbee is a non-contact team field sport played with a flying disc. The sport is ruled by the World Flying Disc Federation that was recognized by the IOC in 2015, making the ultimate Frisbee eligible for including in the Olympic Games. As any other team sport the main objective is to make goals, using basics fundaments to score. Thus, the aim of this work was to analyze the reliability and validity of technical indicators in the ultimate Frisbee. Methods A survey was applied to 5 experts, that aimed to validate technical indicators for game fundaments, 4 evaluators used the experts answers to elaborate a protocol of variables to be analyzed and validated. The validation protocol was divided in 2 days. First day, in pairs, the evaluators measured the technical indicators, using the Dvideo system, 5500 frames of a world championship game, using the technical indicators standardized by the experts. The frequency of analyses was 7.5 Hz. The standardized technical indicators were 14, including the basics ones like the pull, pass, diving, assistance and others more specific like the kind of the pass. In the second day, the evaluators individually measured another game of the world championship 2015 to test the reliability and validity. This time they measure 9000 frames. The results of the technical indicators of the 4 evaluators were compared using the Kappa Cohen Test. Results The results shows that during the game analysis we had 4 pulls and 3 goals, the USA team had 38 complete passes, 5 incomplete passes, considering that 27 were backhand and 16 forehand, against the Great Britain that had 30 complete passes, 7 incomplete passes, considering that 21 were backhand, 15 forehand and 1 hammer. The score was 3x0 for USA. The reliability of the observations between evaluators were tested using the Kappa Cohen Test. The test was conducted in pairs for all evaluators and the measurement of agreement was 0.867 (± 0.031). The interpretation of the kappa value by Altman (1991) shows that values between 0.81-1.00 are considerable almost perfect agreement. Discussion The value of agreement indicates that the technical indicators chosen for this study were very strong to define some variables that can be affected by evaluators subjective measurement in the system. The methodology applied for ultimate Frisbee showed a good reliability and validity to measure technical indicators in this event. The analysis can be performed for a whole game, providing a powerful tool for evaluation of the technical indicators of a match. This kind of data can be used to understand the dynamics of the game and improve the knowledge behind the ultimate Frisbee. Further studies should be conducted to evaluate a whole match. PROTECTIVE EFFECTS OF A TRADITIONAL CHINESE MEDICINE, ANGELICA SINENSIS, ON STRENUOUS EXERCISE-INDUCED SPORTS ANEMIA IN RATS

CHANG, C.W., CHEN, Y.M., HSU, Y.J., HUANG, C.C., WU, Y.T., HSU, M.C.

Kaohsiung Medical University

Introduction Sports anemia is a persistent and severe problem in athletes and attributed mainly to following factors: (a) mechanical destruction of erythrocytes because of oxidative stress, leading to hemolysis (Bonilla et al., 2005); and (b) upregulation in hepcidin-25 expression, an iron-regulating hormone, resulting in iron deficiency (Kong et al., 2014). Angelica sinensis (AS), a familiar traditional Chinese medicine, has been used since antiquity, and is commonly used in Chinese cuisine. The aim of this study is to evaluate the effects of ethanolic AS extract in a 4-week study on sports anemia in female Wistar rats. Methods To induce anemia, a strenuous exercise protocol consisting of running and swimming was employed with increasing intensity. Animals were randomly assigned to the following groups: control group; strenuous exercise group; and strenuous exercise and AS extract-treated group (300 mg/kg/d). After 4 weeks, rats underwent exhaustive swimming and forelimb grip strength test. The blood biochemical markers and hepatic antioxidant activity were determined. Hepatic interleukin-6 was observed through immunohistochemical staining. Results AS extract (consisting of ferulic acid, Z-ligustilide, and n-butylidenephthalide at 1.57, 17.78, and 0.43 µg/mg, respectively) treatment improved grip strength and rescued exercise-induced anemia by significantly elevating the red blood cell count and hemoglobin as well as hematocrit levels ($P < 0.05$). Furthermore, serum hepcidin-25 levels decreased by 33.0% ($P < 0.05$), whereas iron levels increased by 34.3% ($P < 0.01$). The hepatic injury markers serum alanine aminotransferase and hepatic interleukin-6 were also attenuated, followed by increased catalase expression in the liver ($P < 0.05$). Conclusion Our findings first evidenced a novel and promising therapeutic approach for AS treatment for rescuing the anemic condition induced following 4 weeks of strenuous exercise. Further research on the effects of AS in humans is warranted. References Bonilla, J.F., Narváez, R., Chaire, L. (2005). Colombia Médica, 36, 281-286. Kong, W.N., Gao, G., Chang, Y.Z. (2014). RUTOSIDE AND HYDROLYTIC ENZYMES ENHANCE ANTIOXIDANT CAPACITY AFTER VIGOROUS EXERCISE

GRABS, V., HALLER, B., PRESSLER, A., NIEMAN, D.C., HALLE, M., SCHERR, J.

Technische Universität München

Introduction: Vigorous and prolonged exercise such as marathon running results in a major increase of oxidative stress. Nutritional supplements, especially polyphenol-rich nutrients, are being tested as countermeasures of exercise-induced oxidative stress. Methods: In a prospective randomized, double-blind, placebo-controlled Phase I trial we supplemented healthy male runners ($N=138$, age 42 ± 11 y) with rutoside (600-1200 mg/day) and hydrolytic enzymes (540-1,080 mg/day bromelain, 288-576 mg/day trypsin) (WOB) or placebo for one week before and two weeks after the Munich Marathon 2013. Blood samples were collected 5 weeks pre-race, and immediately, 24-h, and 72-h post-race, and analyzed for markers of oxidative stress (myeloperoxidase (MPO), total antioxidant capacity (TAC) and oxidative capacity (TOC) as well as muscular damage (myoglobin, MYO). Mann-Whitney-U test was conducted to compare both groups. Results: TAC was significantly higher in WOB compared to placebo 24 hours post-race (median [IQR]: 375 [366-386] µmol/L vs. 369 [347-383] µmol/L, $p=0.036$). No significant group differences were observed 24-h post-race for TOC (WOB: 177 [114-229] vs placebo: 176 [100-247] µmol/L, $p=0.538$), MPO (726 [564-942] vs 671 [580-940] ng/ml, $p=0.730$) or MYO (140 [91-206] vs 144 [86-230] µg/L, $p=0.790$). No significant group differences for TAC, TOC, MPO or MYO were seen at all other blood collection time points (all $P>0.05$). Finishing time (WOB: 3h 49min \pm 36min vs. placebo: 3h 37min \pm 38min $p=0.066$) and maximum oxygen uptake (VO_{2max}) (WOB: 3.79 \pm 0.53 vs. placebo: 3.87 \pm 0.54 L/min, $p=0.351$) did not differ significantly between WOB and placebo groups. Furthermore, higher oxidative stress levels (TOC) were associated with higher marathon finishing times (Pearson correlation coefficient: $r=0.24$ $p=0.005$). Discussion: Supplementation with rutoside and hydrolytic enzymes before and after a marathon race enhances postrace antioxidant capacity without influencing oxidative stress. Supplementation also had no effects on endurance performance or muscular damage in this group of non-elite male marathon runners.

EFFECTS OF DIFFERENT WEIGHT-LOSS PERIODS ON OXIDATIVE STRESS STATE IN MALE COLLEGIATE WRESTLERS

MIO, N., HIROKI, T., HYEON KI, K., KARINA, A., MI, X., MASAYUKI, K., SHIZUO, S.

Waseda University

Introduction Generation of reactive oxygen species is the physiological metabolic process of normal cells that is controlled by the antioxidant activity. High concentrations of reactive oxygen species result in damage to DNA, proteins, and lipids, which can cause cell and tissue impairment. Rapid weight loss (RWL) is characterized by transitory weight loss of at least 5% of body weight in less than a week (Khodaee et al. 2015). Rapid weight reduction in wrestlers reduced blood adiponectin level and increased their active oxygen level (Yanagawa et al. 2010). The survey of the All Japan Wrestling Championship tournament players reported that in the actual situation, wrestlers had excessive weight loss in a short period of less than 7 days. Extreme rapid weight loss rapidly increases generation of active oxygen species; thus, homeostasis might not be maintained. In the present study, we investigated the effect of different weight loss periods on the oxidative stress state in young male collegiate wrestlers. Methods We studied seven student wrestlers (weight: 66.8 ± 8.0 kg) who needed to lose weight rapidly before competing in a tournament. The experiment was conducted in three periods (7 days, 3 days, and 1

day), with a target of 5% weight loss. Each wrestler's body composition and biochemistry index were measured at three time points, namely before weight loss, at weigh-in, and 12 hours after weigh-in. Results For the serum concentrations for the biological antioxidant potential (BAP) test, 2-factor analysis of variance revealed a significant trial-time interaction ($p = 0.049$). No statistically significant differences in the serum concentrations of diacron-reactive oxygen metabolites were observed between trials ($p = 0.254$). Conclusion The present study demonstrates that as an indicator of antioxidant potential, significant interaction was observed between trials in the BAP test. Khodaei M, Olewinski L, Shadgan B. IRISIN INDUCED BY EXERCISE DO NOT RAISE DIET-INDUCED THERMOGENESIS IN HEALTHY ADULTS.

NAGHAVI, N.

sport center of Osaka city university

INTRODUCTION Diet-induced thermogenesis (DIT), is the energy cost required for the digestion and absorption of nutrients during the postprandial period and habitual exercise could modulate it. Irisin is a new protein that is secreted from the muscle into the circulation after acute exercise in mice and humans and induces browning of adipocytes. **METHODS** Nine healthy young volunteers (32 ± 4 years) participated in two experiments. In the exercise (EX) trial, 40 min of exercise on a bicycle ergometer at 60% of heart rate reserve were performed on the day before the assessment of energy expenditure by indirect calorimetry. Serum irisin levels were examined before and immediately after the exercise. In the no exercise (NOEX) trial EE was assessed without exercise in previous day. Blood concentrations of irisin, glucose and insulin were measured before and after the intake of meal. **RESULTS** Irisin was increased following the 40- min exercise. Glucose level increased during the 1-h period after the dietary intake compared with those at baseline in both trials. Serum irisin levels were higher before and throughout the 3-h period after dietary intake in the EX trial compared with those in the NOEX trial, whereas dietary intake did not affect serum irisin level in either trial. Mean diet induced thermogenesis (DIT) was not different between the trials. **DISCUSSION** The potential thermogenic effect of irisin is still controversial in humans. We found the single bout of exercise did not increase DIT measured on the following day. Whether physical activity increases DIT is also a conflicting issue (Lopez, 2000). Previous reports have demonstrated the correlation between habitual exercise and increased DIT. It may be possible that exercise-enhanced sympathetic activity has a synergistic effect on the thermogenic response to dietary intake (Ohnaka, 1998). A single bout of exercise improved insulin sensitivity and that the improvement lasted for 12–48 h (Black, 2005). In this study, postprandial plasma glucose level was not different between the trials, indicating that a single bout of exercise did not influence insulin sensitivity. This may be because the healthy subjects originally presented with good insulin sensitivity. **REFERENCES** Lopez(2000). PHYSICAL ACTIVITY, USE OF PROTEIN SUPPLEMENT AND DAILY LIFE ROUTINE

YASLI, B., ERTETIK, G., BINGÖL, A., SAHİN, F.N.

Ankara University

Purpose: The purpose of this study is to find out the use of protein supplement, physical activity frequency and daily life routine of people who are regularly attending fitness centers in Ankara, Turkey. **Methods:** A face to face questionnaire was applied to 352 participants. 222 of them are males and 130 females (age: males: 24.91 ± 4.93 females: 24.77 ± 4.96 , height: males: 1.78 ± 0.07 females: 1.68 ± 0.07 , weight: males: 77.38 ± 12.80 , females: 57.68 ± 12.87). This questionnaire belongs to University of Palermo's Protein Project, in Italy (<http://www.proteinproject.com/p/board.html>). Data have been collected from regular fitness center attendees in Ankara. Participants are between 16 to 55 years old and none of them were professional bodybuilders. The education level of 41 percent of respondents is high school while 59% have bachelor's degrees or graduate level of study. Accordingly, physical activity frequency and daily life routine were investigated. Additionally, the use of protein supplement and dietary behaviours were examined. **Results:** To the question "What kind of physical activity you are doing?" 65 % of the respondents answered "fitness/resistance training", while other answers included: 6 % group fitness, 5 % individual sports, 4 % team sports. 41 % exercise from six months to two years, 37 percent from two to six months, 14 % two to four years and 7 % 4 years or more. Frequency of protein consumption in the participants is 25.8 %. 97 of them are male and 3 female. 56% of them use addition supplement to protein consumption, mostly amino-acids and creatin. Furthermore 57 % of Protein supplement users use it between two to six months. Mostly participants take whey protein (95 %). When analyzed the adviser, about protein using 74 % of the respondents answer gym coach. At the end of the part in the questionnaire, respondents answer sitting time question to "in a routine day is 5 to 8 hours is 45%. **Conclusion:** Frequency of protein consumption has similarities to other surveys like in Palermo, Italy (Bianco et all, 2011, 2014). Amino-acids and creatin are the supplements most frequently associated with protein consumption. Also in Turkey the Gym's Coach seems to have a key role in providing awareness about protein supplementation, so gym instructors should be educated well about ergogenic aids and supplement use. **References :** Protein supplementation and dietary behaviours of resistance trained men and women attending commercial gyms: a comparative study between the city centre and the suburbs of Palermo, Italy, Journal of the International Society of Sports Nutrition, 2014, Protein supplementation in strength and conditioning adepts: knowledge, dietary behavior and practice in Palermo, Italy, Journal of the International Society of Sports Nutrition, 2011

TRAINED ATHLETES TYPICALLY CONSUME WELL ABOVE 1.2 G DIETARY PROTEIN PER DAY

WARDENAAR, F.1, JONVIK, K.1,2, TROMMELLEN, J.2, GILLEN, J.3, VERSTEEGEN, J.1, BRINKMANS, N.1, VERDIJK, L.2, VAN LOON, L.1,2

1. HAN University of Applied Sciences, Nijmegen, the Netherlands; 2. NUTRIM, Maastricht University, the Netherlands; 3. McMaster University, Hamilton, Canada

BACKGROUND Habitual dietary protein intake should be optimized in all athletes to ensure proper recovery, enhance the skeletal muscle adaptive response to training and improve muscle reconditioning. Besides daily protein intake, the use of specific protein sources as well as the distribution of protein intake over the day are of relevance to optimize dietary protein intake in athletes. **PURPOSE** To assess daily protein intake, dietary protein sources consumed, and protein intake distribution throughout the day in a large cohort of athletes. **METHODS** 553 well-trained (competitive) athletes (327 men and 226 women) completed multiple web-based 24-h dietary recalls and questionnaires within a 2-4 week period. Total energy consumed (MJ) and the contribution of animal and plant based protein sources to daily protein intake (g) were determined and expressed as a percentage of total protein intake. Daily protein intake was categorized into six

eating moments. RESULTS Daily protein intake averaged 108 ± 33 g (1.6 ± 0.5 g/kg) in men and 90 ± 24 g (1.4 ± 0.5 g/kg) in women. Daily protein intake correlated highly with energy intake for strength ($r=0.72$, $P<0.001$), team ($r=0.77$, $P<0.001$) as well as endurance athletes ($r=0.78$, $P<0.001$). Dietary protein intake averaged 19 ± 8 g at breakfast, 25 ± 13 g at lunch and 38 ± 15 g at dinner, contributing together 81% of daily protein intake. The amount of protein per main meal was below the recommended 20 g for 58% of the athletes at breakfast, 36% at lunch and 8% at dinner. Of the total dietary protein intake, 57% originated from animal sources, with meat and dairy as dominant sources. Thus, as much as 43% of the protein intake originated from plant based protein sources, with bread as the principle source. CONCLUSIONS Athletes typically consume well above 1.2 g protein/kg/d with their normal diet. Daily protein intake is mainly (>80%) provided by the three meals, with breakfast and dinner providing 19 ± 8 and 38 ± 15 g protein, respectively. Plant based proteins provide more than 40% of daily protein consumption. Partly supported by a grant from Friesland Campina and Eat2Move, the Netherlands.

THE EFFECTS OF SIX-WEEK PYRAMID RESISTANCE EXERCISE PROGRAM AND SUPPLEMENTARY NUTRITION ON THE INCREASE IN MAXIMUM STRENGTH OF ELITE WEIGHT LIFTER

REISI, J., MARANDI, S.M., DEHGHANI, F.

University of Isfahan

The Effects of Six-Week Pyramid Resistance Exercise Program and Supplementary Nutrition on the Increase in Maximum Strength of Elite Weight Lifter Introduction: The pyramid system is one of the advanced training systems in the field of body building and fitness that used for hypertrophy and muscle mass increase. The goal of this study was to examine the effect of the pyramid system and Consumption of ceratine mono-hydrate and carbohydrate Protein supplements on increasing the muscular strength and 1-repetition maximum. Methodology: for this purpose, 29 of the elite Pressers of Esfahan province (age: 24.58 ± 2.12 , weight: 87.86 ± 6.46) were selected randomly and divided into 3 groups of resistance training+ supplementation (RTS N=10), resistance training (RT=10) and control (N=9) groups. 72 hours before the first exercise and 72 hours after the last exercise session they were taken a record for their chest press using 1-repetition maximum. Results: the findings of this study showed that there was a significant difference between the control and RTS group after going through a six-week resistance exercise program. However, there was no difference between the control and RT group ($P > 0.05$) and the level of progress in the RTS group was higher than in the other two groups ($P < 0.05$). Discussion: it seems that the combination of the pyramid system and ceratine supplements and carbohydrate protein mixtures causes an increase in muscular strength and 1RM in elite weight lifters and using pyramid system alone without the consumption of any food supplements has no effect on muscular strength in the elite weight lifters. Key words: Chest Press, Monohydrate Ceratine, Carbo-hydrate Protein, pyramid system Reference 1- Fish DE, Krabak BJ, Johnson-Greene D. EFFECTS OF A PALEOLITHIC LIFESTYLE ON COGNITIVE PERFORMANCE AND PHYSIOLOGICAL STRESS

KALDEWEY, K., KRUSCHE, T., SANDER, D., STÖRTKUHL, K., PLATEN, P.

Ruhr-Universität Bochum / Faculty of Sports Science

Introduction A paleolithic lifestyle has gained huge popularity among athletes in the recent decade. This lifestyle is associated with a variety of factors (i.e. caloric restriction, altered circadian rhythm, physical exhaustion) that might induce physiological and psychological stress. It has been further shown that stress can lead to an impaired cognitive performance (CP) [1],[3]. Data indicates that HRV can be used as a non-invasive, practical tool in order to reflect physiological heterostasis [1],[2]. Three main objectives were evaluated. First the effect of a paleolithic movement- and diet pattern on physiological cortisol (COR) levels. Second the potential effect of physiological stress on CP. And third the correlation between COR levels and multiple HRV parameters. Methods A group of hikers ($n=13$; age = 21.9 ± 3.1 years) were exposed to the rural area of Lapland including extensive hiking and self-obtainment of nutrients over nine days. Pre- and post testing occurred on d0/d10 (three days prior and post intervention in a 72h window). During d1-d3 the group remained fasted due to insufficient food discovery. During d4-d9 the diet (supplied by local shops) remained hypocaloric and compliant to paleolithic standards. Salivary COR-levels and HRV-markers (SDNN, RMSSD, PNN50, HF/LF) were measured immediately after awakening from d0-d10 every morning. CP was tested midday on d0,d8,d10 including optical and acoustical reaction tests, measuring reaction time, reaction stability and false responses. Results COR increased during intervention ($d0=11.76 \pm 7.91$; $d8=22.10 \pm 8.09$ nmol/l; $d10=19.50 \pm 5.20$ nmol/l, $p=.038$). It peaked on d4 (28.73 ± 8.34 nmol/l, $p=.000$) and slowly levelled off till d10. CP did not change from d0 till d10. Likewise no significant correlation between COR and HRV-markers could be detected. Discussion Physiological stress levels (COR) increased dramatically during an extensive paleo oriented hiking tour. This might be mainly caused by physiological exhaustion and caloric restriction. However there were no considerable changes in CP. The representative role of HRV for stress is currently discussed controversially. Recent studies implied that HRV analysis contains valid parameters, emulating stress levels in order to predict CP [1],[2]. Interestingly our data does not confirm this thesis. HRV-data did not reflect COR adequately. Hence it should be applied with caution in that regard. However the small group size might have account for the lack of significant/representative data. Further studies are recommended. Literature [1] Castaldo,R. et. al. (2015). Biomed Signal Process Control, 18, 370-377. [2] Laborde,S. et al.(2014). Biol Psychol, 100, 34-42. EFFECTS OF INTERMITTENT FASTING COMBINED WITH ALKALINE MINERAL SUPPLEMENTATION AND EXERCISE TRAINING ON WEIGHT LOSS - A 12 WEEK PLACEBO-CONTROLLED DOUBLE-BLIND TRIAL WITH OVERWEIGHT SUBJECTS

MEYER, T.P., HOTTENROTT, L., VORMANN, J., WERNER, T., HOTTENROTT, K.

Martin-Luther University Halle-Wittenberg

Introduction: Intermittent fasting (IF) seems to be a potential strategy for weight loss with good feasibility (Johnstone, 2015). In particular IF combined with exercise suggests to have synergistic effects on weight loss (Bhutani et al., 2013). However, possible effects of an additional supplementation with alkaline minerals on weight loss have not been shown yet. Therefore, the aim of this study was to determine influences on weight loss in exercising overweight subjects with or without IF. Additionally, the influence of alkaline mineral supplementation was tested. **Methods:** 80 overweight subjects, aged 45.5 ± 7.8 years were randomly assigned into two groups following different diet strategies. The intermittent fasting group (IFG) followed an IF program (5:2 method) while the non-intermittent fasting group (nIFG) followed a balanced diet for a period of 12 weeks. In a double-blind placebo-controlled design subjects in both groups took either an alkaline mineral supplement ("verum") (Basica®direkt, Protina Pharm. GmbH) or a placebo twice daily. All subjects performed a personalized endurance training (3-4 times a week). Body weight and body composition were measured with Tanita® BC-545N Segment Body analyzer. Capillary blood samples were analyzed by a blood gas analyzer (profile®, phox®Plus M Analyzer, nova@biomedical, UK) and urine-pH in morning urine with pH-sticks (Macherey-Nagel, Germany). **Results:** Two-way ANOVA showed significant differences in mean weight loss between IFG (-7.8 ± 3.9 kg) and nIFG (-4.8 ± 3.4 kg). There was also a significant main effect of alkaline supplementation (verum -7.4 ± 4.1 and placebo -5.2 ± 3.5) on weight loss ($p < 0.01$). No significant difference was found between dietary strategy and supplement intake. IFG-verum participants lost 9.45 ± 3.68 kg while IFG-placebo lost 6.51 ± 3.49 kg during the 12 weeks of intervention (independent t-test, $p = 0.034$). The weight loss in nIFG-verum (5.7 ± 3.66 kg) and nIFG-placebo (3.89 ± 3.13 kg) differed as well, but did not reach statistical significance ($p = 0.139$). Alkaline supplementation significantly increased $[HCO_3^-]$ and urinary pH in IFG and nIFG with verum intake as well. **Discussion:** Intermittent fasting and exercise result in a significantly greater weight loss than exercise alone. Alkaline supplementation additionally increased weight loss indicating an influence of acid-base balance on body weight especially in IF. Johnstone A., (2015). IJO, 39(5), 727–733, Bhutani S., Klempel, MC., Kroeger, CM., Trepanowski, JF., & Varady, K.A (2013). Obesity, 21(7), 1370–1379.

PUBERTAL STATUS INFLUENCES MECHANICAL EFFICIENCY IN OBESE VS. NON-OBESE CHILDREN AND ADOLESCENTS DURING A CYCLING TEST

MARTÍN-GARCÍA, M.1, PLAZA-CARMONA, M.2, GARCÍA-CUARTERO, B.3, CARCAVILLA, A.4, ARA, I.1

1 GENUD Toledo Research Group, UCLM, Spain. 2 IGOLD Research Group, UCLM, Spain. 3 Hospital Severo Ochoa (Spain). 4 Hospital Virgen de la Salud (Spain)

Introduction In the physical activity related fields, mechanical efficiency (ME) is defined as the ratio of work done (W) to energy expended (EE) expressed as a percentage ($ME = (W/EE) * 100$) (Bassett and Howley, 2000). Studies that examined ME in relation to obesity status have been focused on adult population. Among those few that included children some discrepancies in their results have been found (Jabbour et al., 2013; Butte et al., 2007). Therefore, the aim of this study was to analyze ME at the maximal workload during cycling exercise in children and adolescents according to their body mass index (BMI) status depending on their gender and pubertal development. **Methods** A total of 177 participants (normal-weight-NW n=58; overweight-OW n=42; obese-OB n=78; Cole et al., 2000) aged from 7.5 to 16.8 years old took part in the study (42.7 % boys; BMI from 13.2 to 41.1 kg/m²). An incremental exercise test to volitional exhaustion on a cycloergometer (Ergometrics 800, Ergoline, Germany) was carried out in order to assess the VO₂ peak (the highest value averaged each 10 seconds), the maximal workload and calculate the EE at the highest intensity (Garby and Astrup's formula, 1987). Finally, self-assessment of the Tanner test in order to register their pubertal development was performed. Results ANOVA test showed a significantly higher ME in pubertal children (Tanner IV-V) in comparison to pre-pubertal children (Tanner I-II) ($F_{2,175} = 5.58$, $p = .004$: 17.4 ± 1.5 % vs. 16.1 ± 2.7 %, respectively, $p = .009$). In contrast, no differences in the ME between boys and girls, neither among NW, OW and OB were found. Nevertheless, when we analyze the data sorted by pubertal development together with obesity status, NW prepubertal children had a higher ME than OB prepubertal children in ME ($F_{2,98} = 3.37$, $p = .038$: 16.8 ± 3.1 % vs. 15.4 ± 2.1 %, respectively, $p = .058$). **Discussion** Similar to Jabbour et al. (2013), we did not find different ME values in NW, OW and OB participants. However, when children were split according to their pubertal development, our results highlight that different ME between NW and OB children is present. Further research is needed to confirm the mechanism that could explain these differences in obese vs. non-obese children. References Bassett DR Jr, Howley ET.(2000).Med Sci Sports Exerc,32(1),70-84. EFFECTIVENESS OF HIGH INTENSITY INTERVAL TRAINING FOR DECREASING ABDOMINAL FAT MASS IN POSTMENOPAUSAL WOMEN WITH TYPE 2 DIABETES

MAILLARD, F., ROUSSET, S., TRAORE, A., METZ, L., DE PRADEL DEL AMAZE, P., BOIRIE, Y., DUCLOS, M., BOISSEAU, N.

AME2P

INTRODUCTION: Estrogen deficiency favors upper body obesity, including visceral fat mass (FM). The combined effects of type 2 diabetes (T2D) and menopause expose this population to a higher risk of cardiovascular disease (CVD). This study compared the effects of moderate-intensity continuous training (MICT) and high intensity interval training (HIIT) for 16 weeks on abdominal FM in postmenopausal women with T2D. **METHODS:** Seventeen women (69 ± 1 years; BMI: 31 ± 1 kg/m²) were randomly assigned to perform MICT [40-min at 55-60% of HR_{max}] or HIIT [60 x 8s at 77-85% of the estimated HR_{max}, 12s active recovery] cycling program. Dual-energy x-ray absorptiometry (DXA) was used to measure whole-body and regional FM and fat-free mass (FFM). Total and visceral FM at the level L4-L5 were determined from DXA (Martin and Jensen 1991) and CT-scan (Sotlier et al. 2013), respectively. Nutritional intake and physical activity level were established with seven-day self-reports. **RESULTS:** Dietary pattern, physical activity level and total body mass did not vary in both groups. Over-

all, total FM decreased and total FFM increased over the time ($p<0.05$). Total FM reduction at the end of the training intervention was not significantly different between groups. Loss of total abdominal (-8.3 % \pm 2.2) and visceral (-24.2% \pm 7.7) FM were only observed in the HIIT group ($p<0.05$). The CT-scan confirmed the significant loss of visceral FM at the level L4-L5 in the HIIT group ($p<0.05$). DISCUSSION: Total abdominal and visceral FM were significantly reduced after HIIT but not with the MICT program. In conclusion, for the first time, we demonstrate that HIIT could be proposed as an alternative training program against central obesity and consequently might be used to counteract CVD risks in postmenopausal women with T2D. SKELETAL MUSCLE MASS INDEX AND BONE MINERAL DENSITY IN A GROUP OF LEBANESE ELDERLY MEN

BERRO, A., ALWAN, A., NASR, R., BADDOURA, R., EL HAGE, R.

Balamand university

Introduction: Muscle mass decreases with age, leading to "sarcopenia" or low muscle mass, in elderly people [1]. The aim of this study was to compare bone mineral density in elderly men with sarcopenia and elderly men with normal skeletal muscle mass index. Methods: This study included 15 elderly men (aged between 65 and 84 years) with sarcopenia and 37 age-matched controls (with normal skeletal muscle mass index). Body composition and bone mineral density (BMD) were assessed by dual-energy X-ray absorptiometry (DXA). We used the skeletal muscle mass index (appendicular skeletal mass (ASM)/height²) to define sarcopenia as previously described [1]. A skeletal muscle mass index (SMI) < 7.26 kg/m² was defined as the cut point for sarcopenia [1]. Bone mineral content (BMC) and BMD were measured at whole body (WB), lumbar spine (L1-L4), total hip (TH) and femoral neck (FN). Results: Weight, lean mass, fat mass, SMI and body mass index (BMI) were significantly higher in men with normal SMI compared to men with sarcopenia. BMC and BMD values were not significantly different between the two groups. In the whole population, SMI was positively correlated to WB BMC, WB BMD, L1-L4 BMD, TH BMD and FN BMD. Conclusion: This study suggests that SMI is a positive determinant of bone mineral content and bone mineral density in elderly men. MEASURED AND PREDICTED RESTING METABOLIC RATE IN ADOLESCENT SYNCHRONIZED SWIMMERS.

DI GIACOMO, A.1, GHIANI, G.1, MAGNANI, S.1, VANNI, S.1, SAINAS, G.1, PALAZZOLO, G.1, DONEDDU, A.1, CRISAFULLI, A.1, TOCCO, F.1

University of Cagliari

Introduction The use of predictive equations is the most viable method for basal metabolic rate (BMR) estimation in both general population and athletes, as equations are easy to apply and costless. However, several authors have shown that equations can be imprecise and can under- or over-estimate BMR, especially when they are applied in high-level athletes or in ethnic groups that differ from the original studies that validated such equations. For this reason the use of indirect calorimetry (IC) is preferable to measure BMR in athletes (Moreira da Rocha et al., 2005). The aim of this study was to evaluate BMR in adolescent practicing synchronized swimming using two methods: IC and two of most recommended equations by the Italian Nutrition Society. Methods 13 elite synchronized swimmers (age 15±1.0 years, Body Mass Index 21±2.4, Fat Mass 26.7±8.4%) took part in the study. BMR was measured after an overnight fast and athletes were instructed to abstain from physical activity for twelve hours before the BMR assessment. During the IC session, oxygen uptake (VO₂) and carbon dioxide production (VCO₂) were measured breath by breath by means of a gas analyzer (MedGraphics Breeze, St. Paul, MN) calibrated immediately before each test. With the patient supine and awake, VO₂ and VCO₂ were obtained for 30 minutes. The first 10 minutes of registration were excluded from calculation. BMR was calculated also using two equations: the Schoefield' (SCH) and the Harris Benedict' (HB). BMR obtained with the three methods were compared by means of the one-way analysis of variance. Moreover, the Bland and Altman (1986) plot was carried out to estimate agreement among methods. Results The two equations systematically underestimated BMR as compared to IC (HB=1380.0 \pm 71.9 and SCH= 1377.0 \pm 71.1 vs. IC=1542.5 \pm 241.5 kcal/day, $p>0.01$). The Bland and Altman statistics showed that the 95% limits of agreement were within +558.7 and -233.5 kcal/day (IC-HB) and +569.0 and -238.0 kcal/day (IC-SCH). Discussion Coaches and athletes need to be aware of limits related to the use of equations for estimating BMR in adolescent synchronized swimmers. Probably, the BMR underestimation is related to a higher free fat mass percentage in our sample with respect to the reference population of control adolescents. References Bland JM, Altman DG. THE EFFECTS OF AEROBIC EXERCISE TRAINING ON PLASMA AMINO ACID CONCENTRATIONS IN OVERWEIGHT AND OBESIVE MEN

MYOENZONO, K., YOSHIKAWA, T., KUMAGAI, H., TSUJIMOTO, T., TANAKA, K., MAEDA, S.

University of Tsukuba, Ibaraki, Japan

Introduction The plasma amino acid concentrations predict various disorders (e.g., cancer, liver disease and hypertension). The high plasma concentrations of valine, leucine, isoleucine, tyrosine and phenylalanine have been identified as strong predictors for type 2 diabetes mellitus, which are independent of insulin resistance measures. Obesity, a major risk factor for type 2 diabetes mellitus, is related to these increased plasma amino acid concentrations. Previous studies have shown that aerobic exercise training improves insulin resistance in overweight and obese individuals. However, the effects of aerobic exercise training on plasma concentrations of valine, leucine, isoleucine, tyrosine and phenylalanine have not been clarified yet. The purpose of the present study was to investigate the effects of aerobic exercise training on the plasma amino acid concentrations in overweight and obese men. Methods Thirty-five overweight and obese men completed the 12-week aerobic exercise training. The subjects participated in aerobic exercise classes for up to 90 minutes/day, 1-3 times /week for 12 weeks. The exercise program includes 10-15 minutes warm-up session, 40-60 minutes walking and/or jogging session and 15-20 minutes cool-down session. In addition, participants were instructed not to change their dietary habits. Anthropometric measures, homeostasis model assessment of insulin resistance (HOMA-IR) and plasma concentrations of amino acid were evaluated before and after the intervention. Results After the 12-week aerobic exercise training, the number of steps increased significantly, whole body mass, body mass index, waist circumference and HOMA-IR decreased significantly. The plasma concentrations

of valine, leucine, isoleucine, tyrosine, and phenylalanine significantly decreased after the program. Discussion In the present study, the plasma concentrations of valine, leucine, isoleucine, tyrosine and phenylalanine significantly decreased after the 12-week aerobic exercise training in overweight and obese men. Additionally, similar to the previous studies, HOMA-IR significantly decreased after the program. We firstly suggest that the 12-week aerobic exercise training in overweight and obese men has anti-diabetic effects through not only the improvement of insulin resistance, but the decreases in the plasma amino acid concentrations.

CARDIOMETABOLIC BENEFITS OF MODERATE-TO-HIGH INTENSITY INTERVAL TRAINING COMPARED TO TRADITIONAL TRAINING MODALITIES

GLEADALL-SIDDALL, D., BURKE, R., GRITT, J., O'CARROLL, G., BRAY, J., DOUGLAS, C., INGLE, L., GARRETT, A.

The University of Hull

Introduction High-intensity interval training (HIIT) may be a time efficient strategy compared with traditional endurance (END) and resistance (RES) training for inducing cardiometabolic adaptations. Most HIIT protocols incorporate maximal or supramaximal repeated sprints which require a high level of conditioning and are difficult to undertake, especially for the lesser trained. A moderate-to-high intensity interval training programme (MO-HIIT) is a modification, which incorporates longer, less intense intervals. It is unknown if MO-HIIT confers similar adaptations to cardiometabolic and psychosocial health as traditional training. Methods Participants were matched for baseline VO₂peak and assigned ($n=9$ per group) to either a non-exercise control (CON) or one of three, 6-wk supervised training modalities (3 sessions per week). 1) MO-HIIT: 28-min cycle ergometer protocol involving 5 x 2-min intervals at 80%, 88% and 97% PPO (wks 1-2, 3-4 and 5-6) interspersed with 2-min recovery (50W); 2) END: 55-min protocol involving 45 minutes of continuous cycling at 55%, 61% and 67% PPO (wks 1-2, 3-4 and 5-6) plus 10-min warm up and recovery; or 3) RES: 55-min gym-based training involving 8 exercises; 3 sets at ~80% RM. Pre- and post-intervention measures were: a direct VO₂peak estimation, oral glucose tolerance test (OGTT), safety rates, participant adherence and experience measured using Profile of Mood State (POMS). Results Thirty-six males (VO₂peak; 36.9 ± 7.2 ml/kg/min) were recruited. For MO-HIIT, VO₂peak increased 15.4% (d: 5.3; 95% CI, 2.9 to 7.8 ml/kg/min; $P=0.001$), and in the END group, VO₂peak increased 9.4% (d: 3.5; 95% CI, 2.0 to 5.0 ml/kg/min; $P=0.001$), with no differences between conditions ($P=0.46$). In RES, there was a non-significant increase in VO₂peak (3.6%; d: 1.4; -1.0 to 3.8 ml/kg/min; $P=0.21$) and in CON, VO₂peak remained unchanged (0.7% increase; d: 0.2; -1.4 to 1.8 ml/kg/min; $P=0.73$). Following OGTT, blood [glucose] decreased in RES (14.9%; d: -1.0; -1.7 to -0.3 mmol/L; $P=0.01$), with no differences in the other groups ($P>0.05$). Exercise adherence was >95%, with no differences between conditions ($P=0.29$). No participant withdrew from a training group due to safety. The POMS indicated RES and END improved mood pre-post exercise, MO-HIIT resulted in reductions in mood. Discussion Our MO-HIIT protocol provided similar cardiometabolic adaptations as a traditional END programme, in half the training time. Therefore, MO-HIIT may be a more time-efficient strategy which offers similar levels of safety and adherence. Further research is required in wider cohorts including women, sedentary groups, and the elderly. Contact d.gleadall-siddall@hull.ac.uk

ESSA-ECSS EXCHANGE: ECCENTRIC EXERCISE IN PATIENTS WITH CHRONIC HEART FAILURE

MCKEOWN, L.C., NAYLOR, L.H., MAIORANA, A.J., NOSAKA, K.K., GREEN, D.J.

University of Western Australia

Introduction: Patients with chronic heart failure (CHF) exhibit profound levels of exercise intolerance and impaired aerobic capacity (VO₂peak), with implications for clinical outcome. Exercise training improves VO₂peak, and consequent prognosis, but prescription is challenging, as exercise performed at workloads sufficient to induce adaptation can be associated with significant cardiovascular burden and disease exacerbation. In healthy populations, eccentric (ECC) exercise can be performed at a lower O₂ demand, compared to concentric (CON) at matched workloads. ECC exercise therefore potentially represents a clinically relevant alternative to conventional CON exercise for CHF patients, but there is a paucity of research pertaining to this. We hypothesised that, when matched for external workload, an ECC exercise bout would be performed at a lower VO₂ than CON in CHF patients. Methods: Seven CHF patients (6 males) with impaired left systolic function (EF: $35\pm7\%$) completed a cycle VO₂peak test, with subsequent ECC and CON cycling protocols set to 70% of individual maximal power. VO₂peak, respiratory exchange ratio (RER), minute ventilation (VE), heart rate (HR), rate pressure product (RPP) and mean arterial pressure (MAP) were compared between the ECC and CON exercise conditions. Results: Results indicated that ECC was performed at 15% lower VO₂ (11.3 ± 1.3 vs 13.3 ± 1.6 ml.kg⁻¹.min⁻¹, $P<0.01$), lower RER (0.86 ± 0.03 vs 0.90 ± 0.04 , $P<0.01$) and VE (31.9 ± 4.1 vs 34.6 ± 5.2 L/min, $P=0.05$) compared to CON, despite closely matched workloads (Watts). RPP ($11,903\pm847$ vs $10,884\pm311$ bpm.mmHg⁻¹, $P=0.23$) and MAP (91 ± 0.1 vs 89 ± 1.6 mmHg, $P=0.32$) were similar between conditions. Discussion: Achieving a similar exercise workload, with a significantly lower oxygen demand, is a clinically relevant and novel finding for CHF patients who are characterised by dyspnoea and poor exercise tolerance. Results also indicated that MAP and RPP were similar between conditions, an important finding confirming that ECC exercise can be performed with a similar haemodynamic burden to CON exercise in CHF patients. The corollary of these findings is that at a matched %VO₂peak, higher workloads can be performed during ECC than CON. Attaining greater stimulus at the muscle to induce peripheral adaptations, without a concomitant rise in haemodynamic burden, suggests that ECC exercise represents a new and promising paradigm for cardiac rehabilitation in severely deconditioned humans. CARDIOPULMONARY RESUSCITATION CHARACTERIZATION: IS IT DIFFERENT FOLLOWING A 100m RUN? Sousa, A.1, 2, Rodriguez, N. 3, Fernandes, R.J.1,2, Abraldes, J.A. 1, 4: CIFI2D, Faculty of Sport (University of Porto, Portugal), 2: LABIOMEP (University of Porto, Portugal); 3:

Department of Physical Activity and Sport, Catholic University of San Antonio, Murcia, Spain; 4: Department of Physical Activity and Sport, Faculty of Sports Sciences, University of Murcia, Murcia, Spain

Introduction The quality of cardiopulmonary resuscitation (CPR) is a crucial determinant of outcome following cardiac arrest (Adelborg et al., 2011). Traditionally, the CPR is not performed by the rescuer in resting conditions, but after an intense run towards the victim. This could lead to differences in the quality of the inflations for the victim, who requires an optimal quality of oxygen. The cardiopulmonary characterization of the CPR in these two distinct conditions has not been investigated, still being unknown the effect of 100m running on subsequent CPR.

Methods Sixteen male highly trained health emergencies technicians (mean \pm SD; age: 25.9 ± 6.1 yrs, height: 177.5 ± 5.5 cm and body mass: 76.7 ± 9.4 kg) performed two experiments (both on a manikin): (i) 4 min CPR preceded by 3min baseline and (ii) 4min CPR preceded by a 100m maximal run. CPR was performed according to the European Resuscitation Council 2005 guidelines (Handley et al., 2005). Cardiopulmonary parameters were assessed breath by breath (averaged 10s) using a portable and telemetric gas analyser (K4b2, Cosmed, Italy) and their peak values (VO₂peak and HRpeak) determined as the higher values during the 4min CPR exercises. Results When preceded by 3min baseline, VO₂ and HR kinetics evidenced a fast exponential increase in the first seconds of exercise followed by a slow increase towards the end of the exercise. When CPR was preceded by 100m maximal run, the kinetics of both parameters evidenced the opposite trend (exponential decrease). The mean (\pm SD) values for VO₂peak and HRpeak were: 25.3 ± 4.8 vs 41.1 ± 5.5 ml.kg⁻¹.min⁻¹ ($P < 0.001$) and 125.5 ± 9.3 vs 168.1 ± 12.1 bpm ($P < 0.001$) when preceded by 3min baseline and 100m maximal run, respectively. The 100m maximal run induced an increase of ~64 and ~35% in VO₂peak and HRpeak, respectively. Discussion Results indicate that performing a previous 100m maximal run induces changes in the kinetics of VO₂ and HR, as well as significant increases in their peak values during 4min CPR. This data highlights the importance of a fatigue state when conducting CPR that should be considered as an effective training stimulus when technicians in health emergencies perform this maneuver, ensuring a high quality of the inflations for the victim.

THE EFFECT OF SPORT ON COMPUTERIZED ELECTROCARDIOGRAM ST AND J AMPLITUDE IN AMATEUR ATHLETES*

NIE, J.1, LIN, H.2, KONG, Z.3, TONG, T.4, FONG, S.1, SHI, Q.1

Macao Polytechnic Institute

1: MPI (Macao, China). 2: LNNU (Dalian, China). 3: UMAC (Macao, China). 4: HKBU (Hong Kong, China).

Introduction The addition of the electrocardiogram (ECG) to the pre-participation examination (PPE) of athletes has been a topic for debate. Defining the ECG difference among sports modalities is crucial to help initiate its implementation in the PPE. In addition, ECG early repolarization (ST and J-point elevation) was associated with reduced overall survival and an increased risk for arrhythmic death (Tikkanen et al., 2009). Thus, we endeavored to provide more insight on the influence of sports modalities on ST and J-point amplitude in amateur athletes.

Methods Computerized 12-lead ECGs were obtained in 131 male athletes (mean age 24.2 ± 3.5 years) and 48 matched sedentary male controls (mean age 24.5 ± 2.7 years) with a normal cardiovascular physical examination and without family and personal history of heart disease. Athletes were engaged in 9 different sports and were grouped into 4 categories: long-distance running, football/basketball/handball, judo/karate/taekwondo/boxing and dragon boat. The analysis focused on ST segment and J-point voltages of ECG 12 leads. Results ANOVA analysis yielded significant ST segment and J-point amplitude differences among sports in V3, V4, V5 and V6 ($p < 0.05$). Specifically, The highest ST segment and J-point amplitude were found in long-distance runners and the shortest ones were found in players of judo/karate/taekwondo/boxing (V3-V6) and/or controls (V5). No significant amplitude differences among sports were found in ST segment and J-point in other leads ($p > 0.05$).

Discussion This study was intended to provide a set of amateur athlete data to validate the implementation of the ECG in the amateur athletic PPE. The present study showed that the differences in ST and J amplitude in amateur athletes are strongly associated with sports modalities. This suggests that sports-specific criteria for abnormal ECG findings are necessary to facilitate a more effective approach to the ECG screening in amateur athletes. Establishing the different parameters set for various sports modalities ECG would help to reduce false positives. Our data can help facilitate the development of a more large scale and in-depth ECG analysis for screening amateur athletes in the future.

STRENGTH AND FLEXIBILITY IS IMPAIRED IN CHILDREN AND ADOLESCENTS WITH CONGENITAL HEART DISEASE

REINER, B.1, WEBERRÜB, H.2, OBERHOFFER, R.1,2, EWERT, P.1, MÜLLER, J.1,2

1 German Heart Centre Munich; 2 Technical University Munich

Introduction: While the mortality rate of children with congenital heart disease (CHD) has decreased it's becoming more important to observe long-term outcomes. In fact, many studies have shown that an adapted level of activity for children, adolescents and adults with CHD is safe and beneficial. Cardiovascular, muscular, functional and psychological benefits were reported. Nevertheless, many of these young patients tend to be inactive [1]. The aim of this study is to evaluate strength and flexibility, as important factors for a healthy development.

Methods: 425 children (aged 6-18 years) with CHD were recruited during their follow-up appointment at the German Heart Centre Munich from July 2014 until February 2016. All patients were assigned to one of the following diagnostic subgroups: Aortic Coarctation/Aortic Stenosis (CoA/AS n=100), Tetralogy of Fallot/Pulmonic Stenosis (ToF/PS n=65), Atrial Septal Defect/Ventricular Septal Defect/Atrioventricular Septal Defect (Shunts n=115), Transposition of the Great Arteries (TGA n=50) and Univentricular Heart (UVH n=65). All patients (12.6 ± 3.3 years, 161 female) performed five motoric tests. Strength was tested by the number of completed Curl-Ups (abdominal strength) and Push Ups (upper body strength). Further three flexibility tests were performed: trunk lift, sit and reach (determining hamstrings) and shoulder stretch. Patients' data were compared to 1018 healthy children (11.9 ± 2.6 years, 534 female). A multivariate regression model was calculated to control sex and age.

Results: Compared to healthy controls, children and adolescents with CHD had deficits in motor development, even after correction for sex and age. In average they performed less than seven Curl-Ups ($p < .001$), showed lower trunk strength/flexibility ($B = -7.3$ cm; $p < .001$), shoulder flexibility ($B = -4.5$ cm; $p < .001$) and hamstring flexibility ($B = -4.4$ cm; $p < .001$). According to Push-Ups, there were no differences. In-between the diagnostic subgroups, there were no differences found in strength tests. Trunk ($B = 1.9$ cm; $p = .046$) and shoulder flexibility ($B = 2.2$ cm; $p = .044$) was better in CoA/AS patients, while patients with UVH showed less shoulder flexibility ($B = -2.7$ cm; $p = .027$).

Conclusion: Nowadays, cardiologists explicitly recommend an active lifestyle for children with CHD, but the patients still have deficits in strength and flexibility. For these young people it is important to evaluate motor skills in routine examinations, to give individualized recommendations for a healthy development.

THE EFFECT OF SPORT ON COMPUTERIZED ELECTROCARDIOGRAM QRS AMPLITUDE IN AMATEUR ATHLETES*

SHI, Q.1, KONG, Z.2, DONG, Y.1, TAM, S.1, NIE, J.1

Macao Polytechnic Institute

1: MPI (Macao, China). 2: UMAC (Macao, China). Introduction Intensive sport training is associated with physiologic cardiac remodeling, which are reflected on the electrocardiogram (ECG) most frequently as an increase of QRS voltages (Corrado et al., 2010). Because of the partial overlap of ECG signs of cardiac hypertrophy, athlete's heart is often in the differential diagnosis with hypertrophic cardiomyopathy, which is the leading cause of sports-related cardiac arrest in young athletes. Though the criteria for abnormal QRS amplitude, requiring additional testing, have been recommended for pre-participation exams of athletes, the criteria have not considered the sport in which athletes participate. Therefore, we examined the effect of sports modalities on the computerized ECG QRS amplitude obtained in amateur athletes. Methods Computerized 12-lead ECGs were obtained in 131 male athletes (mean age 24.2 ± 3.5 years) and 48 matched sedentary male controls (mean age 24.5 ± 2.7 years) with a normal cardiovascular physical examination and without family and personal history of heart disease. Athletes were engaged in 9 different sports and were grouped into 4 categories: long-distance running, football/basketball/handball, judo/karate/taekwondo/boxing and dragon boat. The analysis focused on QRS voltages (R and S wave) of ECG 12 leads. Results ANOVA analysis yielded significant R wave amplitude differences between sports only in V2, V3, V4 and V5 ($p < 0.05$). Specifically, The highest R was found in long-distance runners and the shortest one was found in gymnasts (V2, V4 and V5) or controls (V3). No significant amplitude differences among sports were found in S wave in all 12 leads ($p > 0.05$). Discussion This descriptive study, which shows that R wave amplitude differences exist between sports, is a pioneering step toward the development of sport-specific criteria for abnormal ECG findings. The recognition of the existence of differences in ECG measurements between sports opens the door for further research which should link these ECG changes with structural cardiac changes. Although the significance of these differences in R wave amplitude between sports are not known, it is important to bear in mind the existence of these differences when testing athletes. Therefore, sport-specific ECG criteria for abnormal ECG findings should be developed to obtain a more useful approach to ECG screening in athletes. *The study was supported by a research grant from Macao Polytechnic Institute (RP/ESE FD-02/2012). INFLUENCE OF MATURATION ON MUSCLE DAMAGE AND ARTERIAL STIFFENING AFTER ELBOW FLEXOR ECCENTRIC EXERCISE

TSENG, K.W.1, LIN, M.J.2, HO, C.C.3, CHEN, H.L.2, NOSAKA, K.4, CHEN, T.C.3

1:UT (Taiwan), 2:NCYU (Taiwan), 3:NTNU (Taiwan), 4:ECU (Australia)

Introduction The magnitude of muscle damage after eccentric exercise of the elbow flexors (EF) is significantly smaller for boys than adult men, and for pre-adolescent than adolescent (1). However, it is not known whether this is also the case for women. The present study compared changes in indirect muscle damage markers after EF eccentric exercise among pre-adolescent, adolescent and post-adolescent women. This study also compared changes in carotid-femoral pulse-wave velocity (cfPWV) after EF eccentric exercise among the three age groups, since it is not known whether an increase in arterial stiffness after eccentric exercise (2) is affected by age and the magnitude of muscle damage. Methods Thirteen healthy untrained girls (9-10 y), teens (14-15 y) and adults (>20 y) performed two bouts (EC1, EC2) of 30 submaximal EF eccentric contractions using a dumbbell set at 60% of pre-exercise maximal voluntary isometric contraction strength at 90° elbow flexion with their non-dominant arms (3.6-14.3 kg) separated by 2 weeks. Several indirectly markers of muscle damage (e.g. maximal voluntary concentric contraction torque (MVC-CON), muscle soreness, plasma creatine kinase activity and cfPWV were measured before to 5 days after each exercise. Results MVC-CON and cfPWV before EC1 were different ($P < 0.05$) among the girls (MVC-CON: 10.0 ± 0.7 Nm; cfPWV: 903 ± 106 cm/s), teens (14.3 ± 0.5 Nm, 967 ± 108 cm/s) and adults (19.1 ± 1.0 Nm, 1103 ± 115 cm/s). Changes in all muscle damage variables after EC1 were smaller ($P < 0.05$) for girls and teens than adults, and for girls than teens. After EC2, changes in all muscle damage variables were smaller ($P < 0.05$) than those after EC1 for all groups, but the magnitude of the changes was the same order as that after EC1. Significant increases in cfPWV (peaked 2-3 days post-exercise) were evident for teens and adults, and the magnitude of the increase was smaller ($P < 0.05$) for teens (EC1: 10%, EC2: 2%) than adults (20%, 7%). Discussion These results show that the magnitude of muscle damage after eccentric exercise is less for younger than older women, confirming the findings of the previous study in men (1). The increase in cfPWV appears to be related to the magnitude of muscle damage; the greater the damage, the greater the increase in arterial stiffness. It is concluded that the extent of muscle damage and arterial stiffness changes after unaccustomed eccentric exercise increases with maturation. The less effect of eccentric exercise on the variables seen for children especially for girls may be due to their greater flexibility of muscles. References 1) Chen et al. (2014) EJAP, 114, 1183-95. 2) Barnes et al. (2010) JAP, 109, 1102-8.

THE EFFECT OF SWIMMING ON CARDIAC MITOCHONDRIA FUNCTION OF ADRIAMYCIN INDUCED CHRONIC HEART FAILURE RATS

LI, Y., HUANG, Z.

Guangzhou Sport University

Introduction Exercise intervention has been widely applied in clinical rehabilitation of chronic heart failure(CHF) patients, however, the effect of swimming on cardiac mitochondria function of CHF rats is rarely. Methods 9 weeks aged male SD rats were randomly divided into ADR group and control group (C). ADR were IP by 2,3,3,3,2 mg per kg body weight every 6 days for 5 times respectively. After that rats were divided again into 4 groups: group C, ADR, FEE (begin swimming after 5th IP) and FEL (begin swimming at 4th week after 5th IP).Rats swim 1 time/day and 6 days/week for 6 weeks (15min/time in 1st week, and gradually increased to 25min/time in another two weeks, and to 35min / times in 4th weeks lasting for another two weeks. 6 rats in each group were killed in 3th.6th.9th weekend after 48 hours of last swimming. Rats'ECG and Ventricular blood flow index were acquired by iwox214 system. Myocardial mitochondria membrane potential (MMP) were measured by fluorescence spectrophotometer and flow cytometry, metabolic enzyme by semi-automatic biochemical analyzer. Results After 6W the rats'ECG appeared apparent irregular waveform, T-wave inversion, overlapping waves, etc. On LVEDP, FEE and FEL were lower 41.7% ($p < 0.01$) and 18.4% ($p < 0.05$)than ADR group in 6W,FEL lower 25.6% ($p < 0.05$) in 9W. On +dp/dtmax, FEE were 146.2% and 140.1% of ADR group ($p < 0.01$) in 3W and 6W respectively, FEL were 146.8% and 118% ($p < 0.05$) of the ADR group in 6W.9W respectively. Compared to ADR group, myocardial mitochondrial Na⁺-K⁺-ATPase activity in FEE were 3 times and 2.3 times respectively ,and FEL were 2.2 times and 19.4% $p < 0.05$. On myocardial mitochondrial Ca²⁺-ATPase activity, FEE were 1.12 times and 3.2 times ($p < 0.01$) of ADR group. On myocardial mitochondrial Ca²⁺-Mg²⁺-ATPase activity, FEE were 1.4 times and 3.4 times (p

<0.01) of those in ADR group while FEL were 2 times and 1.7 times ($p < 0.05$). On myocardial mitochondrial Mg²⁺-ATPase activity ,FEE were 1.2 times and 2.6 times ($p < 0.01$) of those in ADR group while FEL were 1.9 times of ADR group in 6W and 9W respectively. The myocardial mitochondrial MMP by flow cytometry in ADR Group were 83%, 40% and 56.7% ($p < 0.01$) respectively. Compared to ADR group, those in FEE were 1.2 times and 1.9 times, and FEL were 2 times ($p < 0.01$) and 1.4 times,respectively. Discussion Cardiac mitochondrial Na⁺ K⁺-ATPase, Ca²⁺-ATPase, Ca²⁺-Mg²⁺-ATPase, Mg²⁺-ATPase activity in CHF rat decline in varying degrees, which can be hampered by exercise intervention(Ahmed and El-Maraghy 2013), and early exercise intervention may be better than late intervention. Early and late exercise intervention are conducive to prevent the decline of MMP in myocardial mitochondria(Montaigne, Marechal et al. 2011),then protect mitochondrial membrane integrity. MO-PM10 Fatigue

REOXYGENATION EFFECTS AFTER PERIPHERAL FATIGUE INDUCED BY ELECTROSTIMULATION WITH OXYGEN DEPRIVATION

CALLE-HERRERO, J., LAZA-CAGIGAS, R., MONTALVO-ZENARRUZABEITIA, Z., DOMÍNGUEZ-CASTELLS, R.

Spanish Agency for Health Protection in Sport

INTRODUCTION: Peripheral fatigue is defined as a failure in the muscle contractile mechanism or a decrease in muscle contraction amplitude. Neuromuscular electrostimulation (NMES) combined with oxygen deprivation can induce muscle fatigue and impair muscle mechanical properties. The aim of this study was to investigate the kinetics of muscular contractile properties during recovery after a fatigue protocol induced by NMES. **METHODS:** Nine physically active men were recruited for this experiment (age: 23.0 ± 3.7 years, height: 178.1 ± 5.8 cm, body mass: 71.9 ± 3.9 kg). One leg was randomly selected to apply a NMES fatigue protocol with oxygen deprivation. The motor point of the vastus medialis was determined and electrodes were placed to apply the NMES fatigue protocol and to conduct TMG measurements (Dm: maximum displacement; Td: delay time; Tc: contraction time). The NMES fatigue protocol consisted of 5 cycles of 72 seconds (Is contraction/Is recovery), with a total of 36 contractions per cycle at a frequency of 40Hz. Intensity was set at individual tolerable limit. Rest between cycles was 40 seconds. A cuff was placed on the leg at groin level and inflated to 300 mmHg for 5 minutes before NMES started, to reduce muscle oxygenation considerably, until the end of fatigue protocol. Immediately after the end of fatigue protocol, the cuff was deflated and muscle recovery started. Measurements of TMG were taken at baseline (PRE), at the end of the fatigue protocol (FAT) and every minute for 10 minutes during recovery (RECn). Muscle oxygen saturation was monitored on the vastus lateralis during the experiment. **RESULTS:** Mean oxygen saturation was $66.0 \pm 5.7\%$ at PRE, $1.6 \pm 1.6\%$ at FAT, $50.24 \pm 7.1\%$ at REC1, $75.2 \pm 6.2\%$ at REC2 and from minute 3 to 10 it was restored to basal levels ($67.0 \pm 8.0\%$). Dm was approximately 45% lower after FAT compared to PRE (4.31 ± 1.99 mm vs 7.89 ± 1.39 mm, $P < 0.001$), and Td was significantly higher in FAT compared to PRE (33.55 ± 9.7 ms vs 22.29 ± 1.3 ms, $P < 0.05$). During recovery Dm was significantly lower in REC1 (3.89 ± 1.84 mm, $P < 0.001$), REC2 (4.99 ± 2.12 mm, $P < 0.001$), REC3 (5.93 ± 2.62 mm, $P < 0.05$) and REC4 (6.35 ± 2.69 mm, $P = 0.064$) compared to PRE. However, Td was only significantly higher in REC1 and REC2 compared to PRE (25.00 ± 2.08 ms and 23.76 ± 1.82 ms, respectively, $P < 0.05$). Tc did not change significantly. **CONCLUSION:** Dm started to increase when the blood circulation was restored. This suggests a progressive muscle fiber activation and increasing muscle contraction amplitude. Furthermore, muscle contractile amplitude was restored to PRE level after 5 minutes of recovery. However, muscle response time (Td) returned to baseline values after three minutes of reoxygenation. This data suggest that the recovery of muscle excitability is faster than the recovery of muscle contractile amplitude. On the other hand, oxygen appears to be the main mediator of the recovery of muscle contractile properties. **CONTACT:** jcalleherrero@gmail.com

MENTAL FATIGUE DOES NOT IMPAIR EXERCISE PERFORMANCE IN TRAINED AND UNTRAINED INDIVIDUALS

CLARK, I., GOULDING, R., BAILEY, S.J., JONES, M.I., FULFORD, J., McDONAGH, S.T.J., JONES, A.M., VANHATALO, A.

University of Exeter

Introduction: Mental fatigue has been associated with a decrement in physical performance in sedentary individuals (Marcora, Staiano, & Manning, 2009) but the impact of mental fatigue on performance in trained athletes, who may exhibit greater mental toughness, has not been investigated. The aim of this study was to compare the effect of mental fatigue on exercise performance in trained and untrained individuals. **Methods:** Following ethical approval, 10 untrained (UNT) ($\text{VO}_{2\text{max}} 38.9 \pm 7.3 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) and 10 trained (TR) ($\text{VO}_{2\text{max}} 58.3 \pm 4.1 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) men performed in a randomised crossover design a 6-min cycling time trial (TT) immediately following a 30-min period of mentally demanding cognitive tasks (MF) and after watching a 30-min documentary film (CON). Heart rate (HR) was measured throughout testing and a positive and negative affect schedule questionnaire was administered at baseline, post MF or CON task and post exercise. **Results:** During the cognitive functioning tasks the UNT group had an elevated HR during the MF condition compared to the CON condition ($\text{MF } 75 \pm 9$, CON 69 ± 7 bpm) ($P < 0.05$), but there was no difference in the TR group ($\text{MF } 59 \pm 6$, CON 58 ± 7 bpm) ($P > 0.05$). In the TR group, positive mood was decreased during both MF and CON (Baseline: MF 33.4 ± 9.1 , CON 33.4 ± 10.7 , Post: MF 25.7 ± 9.9 , CON 28.5 ± 12.0 ($P < 0.05$) and they had a greater negative mood ($P < 0.05$) post MF (15.10 ± 3.7) than after CON (12.2 ± 2.7). The UNT group experienced a lower positive mood post MF compared to post CON condition ($\text{MF } 19.9 \pm 7.5$, CON 24.3 ± 4.6) ($P < 0.05$). TT performance was not different between MF and CON in UNT ($\text{MF } 75.1 \pm 11.0$, CON 73.9 ± 12.2 kJ) or TR ($\text{MF } 102.7 \pm 12.1$, CON 101.8 ± 12.2 kJ) ($P > 0.05$). **Discussion:** Both the TR and UNT individuals exhibited a negative mood profile after the MF intervention compared to the CON intervention. Consistent with past research using the same methods, the intervention to induce mental fatigue was effective in this study. The UNT individuals manifest an elevated HR after the MF intervention whilst the TR individuals did not. However, despite a greater mental fatigue in MF than CON, the physiological responses during exercise and exercise performance were not different between the MF and CON interventions in either TR or UNT individuals. These findings challenge the notion that mental fatigue prior to exercise compromises exercise performance. **References:** Marcora, S. M., Staiano, W., & Manning, V. (2009). EFFECTS OF COMBINED RECOVERY INTERVENTION ON MATCH CHARACTERISTICS, PHYSIOLOGICAL LOAD AND MARKERS OF FATIGUE DURING A MALE SINGLES TENNIS TOURNAMENT

WIEWELHOVE, T., RAEDER, C., DÖWELING, A., BUSCH, M., SZWAJCA, S., FERRAUTI, A.

Ruhr-University Bochum, Faculty of Sport Science

Introduction A survey of national and international elite tennis players showed that especially a combination of active recovery (AR), stretching (S), cold-water immersion (CWI) and massage (M) appears to be most popular among athletes to improve recovery following tennis training and competition. However, scientific evidence of the efficiency of combined recovery intervention is limited. Therefore, the aim of this study was to assess the effects of a combined use of the aforementioned recovery strategies on match characteristics, physiological variables and performance during a singles tennis tournament. **Methods** In a crossover design nine male tennis players (age: 24.1±4.6 years) with a national ranking position were divided into two groups. During a first five-day clay-court tennis tournament, group A received a combined recovery intervention (CRI) that consisted of AR, S, CWI and M, followed by no recovery intervention (passive recovery, PR) for a second five-day clay-court tournament. Group B did not receive a recovery intervention during the first tournament and received the CRI during the second contest. Match characteristics were determined by filming each competitive match with video cameras. Blood lactate concentration (LAC), heart rate (HR) and rating of perceived exertion (RPE) were recorded during each match. In addition, markers of fatigue (countermovement jump height, CMJ; serum concentration of creatine kinase, CK; delayed onset muscle soreness, DOMS) were measured 24 h before, during as well as 24, 48 and 72 h after the tournament. Results No significant intervention x time interactions ($p=0.29-0.86$) were found for markers of fatigue. DOMS and CK significantly ($p<0.05$) elevated during the tournament peaking after the 3rd and 4th match and returning to baseline values 48 h after the tournament. Mean LAC [2.26±0.78 vs. 2.45±0.94 mmol•l⁻¹] (data in brackets are presented as CRI vs. PR)] and HR [142±13 vs. 146±14 b•min⁻¹] as well as RPE values [5.3±0.9 vs. 5.1±1.4 (i.e., hard)] and match characteristics [i.e., total net running distance (2526±1061 vs. 2558±1068 m), number of sprints (98±51 vs. 119±68), total distance that has been covered sprinting (273±139 vs. 321±158 m), total points won, percentage of first serves, number of aces, double faults, errors, and winners] were not significantly different ($p=0.24-0.92$) between conditions. **Discussion** The results suggest that a five-day tennis tournament induces significant changes in markers of fatigue. This is in line with previous research showing increased muscle damage and soreness following a tennis tournament (Ojala & Häkkinen, 2013). Furthermore, the main finding of the study was that a CRI as applied in our study is not able to contribute to a faster recovery during and after a tennis tournament compared to PR and does not affect both match performance variables and physiological responses associated with match play. **References** Ojala, T. & Häkkinen, K. ADOPTING AN EXTERNAL FOCUS OF ATTENTION ALTERS PROCESSING WITHIN THE PRIMARY MOTOR CORTEX AND REDUCES FATIGUE

KUHN, Y., RUFFIEUX, J., KELLER, M., TAUBE, W.

University of Fribourg

Introduction Although it is well established that an external focus (EF) contrasted to an internal (IF) or neutral focus of attention enhances motor performance and learning, little is known about the neural mechanisms underlying these behavioral improvements. This study aimed to i) clarify whether the focus of attention influences the motor performance when executing identical fatiguing tasks of the first dorsal interosseous muscle (FDI) and ii) outline differences in activity of M1. Subthreshold transcranial magnetic stimulation (subTMS) was used to inhibit ongoing motor cortical output without affecting spinal structures [1]. Thus, differences in subTMS-induced EMG suppression between EF and IF indicate distinct activity of M1. **Methods** In session 1, 14 subjects (22-33y; 8 men) performed an isometric index finger abduction at 30% MVC until task failure with either an IF or EF. In a separate session 2, the same task was performed with the other focus. The subTMS protocol comparing the activity of M1 during EF and IF was measured in session 3, but only 10 of the 14 subjects could be used for the final analysis. To prevent the effect of fatigue on the amount of subTMS-evoked EMG suppression, the same motor task as in sessions 1 and 2 was performed, but only at 10% MVC. EMG suppression in FDI was calculated as the difference in the area below the rectified EMG with and without subTMS (cumulative trapezoidal numerical integration). **Results** The time to task failure was significantly prolonged in EF compared to IF ($p = 0.01$). When regarding the background EMG activity, no significant effect of conditions (EF vs. IF) was found. SubTMS resulted in a significantly larger suppression of EMG activity in EF compared to IF ($p = 0.001$). **Discussion** Adopting an EF resulted in a prolonged time to task failure. This was accompanied by a different activity within M1, manifesting in a larger subTMS-induced EMG suppression. As levels of background EMG activity did not differ between EF and IF, we argue that the focus of attention was the dominant modulatory influence on EMG suppression induced by subTMS. From this perspective, the larger inhibition of the ongoing EMG activity suggests that the activity within M1 was greater in the EF condition. In line with the present data, a previous fMRI study has shown an enhanced level of activity within M1 when adopting an EF [2]. As this previous study used a between-subject design, the present within-subject study shows for the first time that the activity within M1 is modulated depending on the type of focus of attention. **References** 1. INCREASED FATIGUE AND FATIGABILITY IN PATIENTS WITH MILD TRAUMATIC BRAIN INJURY

PRAK, R.F., VAN DER NAALT, J., ZIJDEWIND, I.

University Medical Center Groningen

Introduction Fatigue is a disabling symptom for patients with mild traumatic brain injury (MTBI), and can persist for several months post-injury. One model suggests that fatigue is mediated by two dimensions (Kluger et al., 2013): perceptions of fatigability comprise factors influencing fatigue perception by the individual, and performance fatigability refers to impaired task performance. **Methods** Fatigue was quantified in 16 MTBI- and 16 age- and sex-matched control participants using the Fatigue Severity Scale (FSS, Krupp et al., 1989). Performance fatigability was assessed using a fatiguing muscle task. Force recordings were obtained during brief and sustained (2 minute) maximum voluntary contractions (MVC) of the right first dorsal interosseous muscle (index finger abduction). Changes in cortical activation during the sustained MVC were measured using functional MRI (fMRI) and compared between MTBI- and control groups. For the fMRI analysis 10 additional control participants were included. Results MTBI reported higher FSS scores (MTBI: 5.2 ±0.9, control: 2.8 ±1.1, $p<0.01$). Maximal index finger abduction force was not significantly different for MTBI- and control participants (36.0 ±7.4 vs. 37.4 ±9.2 N, $p=0.64$). Force decline, corrected for MVC, was greater in MTBI (61.5 ±9.3 vs. 56.0 ±10.8 % decline, $p<0.01$) and was positively associated with the FSS scores ($R=0.45$, $p=0.012$). During the sustained MVC, fMRI analysis revealed similar patterns of cortical activation in both

groups including: contra- and ipsilateral sensory-motor cortex, ipsilateral cerebellum, and supplementary motor cortex (cluster activation, $P<0.05$, family-wise error corrected). Over the course of the contraction, control participants showed a significant increase in activity in frontal (left superior and middle frontal gyrus; $p<0.001$, uncorrected) and medial areas (bilateral paracentral lobules; $p<0.001$, uncorrected). This increase in frontal activity was not observed in MTBI participants; and a significant difference in activation over time was observed between groups in these areas ($p<0.001$, uncorrected). Discussion Increased fatigue (FSS) and performance fatigability were observed in MTBI participants. Overall, performance fatigability was positively associated with FSS scores. fMRI data showed no change in cortical motor activity between the groups suggesting no major differences in cortical drive. However, MTBI participants were unable to increase activation of frontal and medial areas similar to control participants. This change could reflect differences in the integration of effort- or attention related input. References Kluger BM, Krupp LB, Enoka RM (2013) Neurology, 22;80(4), 409-416. WHAT IS THE BEST METHOD TO EVALUATE MUSCLE FATIGUE? AN EXAMINATION STUDY FOR MEAN POWER FREQUENCY, LACTATE AND CREATINE KINASE

ATTAALLAH, M., ABDELGAWAD, A., SALEH, A.

Faculty of physical Education/Abu-Qir/Alexandria University, Egypt

Introduction Muscle fatigue is generally defined as an activity induced loss of the ability to produce force with the muscle In the previous studies, different variables were used to evaluate the effects of fatigue mean power frequency (MPF), Lactate and creatine kinase (CK) separately. Therefore the purpose of this study was to investigate the relationship between Mean power frequency, Lactate and creatine kinase for lower extremity muscle during 60s continuous jump with bent legs. Methods Nine male college (age=18.2 ± 0.8 y; height=179.4 ± 2.9 cm; mass=85.2 ± 14.5 kg). A Bertec force plate (500Hz) and (Megawin ME 6000 wireless system, Mega Electronics Ltd., Finland) for data collection. Quadriceps Rectus femoris (RF), vastus lateralis (VL), vastus medialis (VM) and biceps femoris (BF) were selected. Root mean square (RMS) used to rectify the signal and the area under signal was calculated for each muscle to determine the percent of contribution on the performance (work/loading) and mean power frequency (MPF) to determine the slope of fatigue. The subjects performed a15-min warm-up and each player performed two trials of continuous vertical jump for 60s (VJ) Results Lactate result show positive significant relationship ($p<0.01$) with vastus medialis (VM). CK show an inverse significant relationship ($p<0.01$) with RF and positive significant relationship ($p<0.05$) with VL and BF. Also there was a significant relationship between CK and Rectus femoris (RF) ($p<0.05$) and no significant relationship between other parameters. Discussion This study showed that no significant relationship between lactate and MPF and this is agreed with the results of other studies (Jansen, et al., 1997; J. T. Viitasalo, Luhtanen, Rahkila, & Rusko, 1985), but no significant change in MPF during repeated measurements. Although we can predict muscle fatigue from MPF unless there was a relationship between the changes in blood lactate and MP. According to our study and other studies for general there no significant correlation between lactate and CK with MPF but there were a significant correlation between CK and muscle activation during the test. The big standard deviation of MPF for some muscles may not found significant relationship. Because it depends on the indication of the slope line values and this is a different between the subjects for each muscle. In the present study CK and work / loading are high correlate and this is lead us to use these parameter to evaluate muscle fatigue References Jansen, R., Ament, W., Verkerke, G. J., & Hof, A. L. (1997). Median power frequency of the surface electromyogram and blood lactate concentration in incremental cycle ergometry. EXERCISE-INDUCED FATIGUE IN SEVERE HYPOXIA IS ATTENUATED IN HEALTHY HUMANS FOLLOWING AN INTERMITTENT HYPOXIC PROTOCOL

TWOMEY, R., WRIGHTSON, J., FLETCHER, H., AVRAAM, S., ROSS, E.Z., DEKERLE, J.

University of Brighton, EIS

Introduction Severe, acute hypoxia leads to an increased development of supraspinal fatigue during whole body exercise (1). This is alleviated following acclimatisation to severe altitude (2), although the development of peripheral fatigue is not (3). Prolonged exposure to severe altitude involves substantial logistical demand, a high incidence of acute mountain sickness and immunological consequences. We assessed the mechanisms of exercise-induced fatigue in severe hypoxia before and after a protocol of intermittent hypoxic exposure and training. Methods Nineteen recreationally-active males performed constant-load cycling trials (186±12W) in normobaric hypoxia (FIO₂ 0.115) before and after an intermittent hypoxic protocol (IH, FIO₂ 0.115, n=11) or control protocol in normoxia (FIO₂ 0.21, n=8). Groups completed ten 2 hr exposures over 14 days. Seven sessions involved cycling for 30min at 77±5W in IH, and at the same relative heart rate in control. Total haemoglobin mass (THbmass) was assessed before and after IH and control using the optimised carbon monoxide rebreathing technique. Peripheral haemoglobin saturation, cerebral oxygenation and blood velocity in the left middle cerebral artery were measured throughout trials. Before and immediately after trials, responses to transcranial magnetic stimulation and femoral nerve stimulation were obtained to assess corticospinal and neuromuscular function, respectively. Results Constant-load cycling performance was improved following IH (535±213 vs. 713±271, $p<0.05$), but not in control. At task failure during baseline cycling trials, maximum voluntary force (MVC), potentiated twitch force (Qtw,pot) and cortical voluntary activation (CVA) for the knee extensors were reduced ($p<0.05$) in both groups. The reductions in these measures were the same at task failure after IH and control ($p>0.05$). However, following an isotime trial in the IH group, the reductions in MVC, Qtw,pot and CVA were attenuated ($p<0.05$). There were no differences in THbmass in IH or control ($p>0.05$). Discussion Exercise-induced supraspinal fatigue, as quantified via changes in cortical voluntary activation, was alleviated after an intermittent hypoxic protocol in comparison to exacerbated levels in acute hypoxia. IH also attenuated the substantial impact of hypoxia on the development of peripheral fatigue. These novel data suggest that improvements in exercise performance in severe hypoxia after IH might, in part, be explained by an attenuated development of both central and peripheral fatigue. CEREBRAL BLOOD FLOW AND OXYGENATION DURING SPRINT EXERCISE AT TASK FAILURE: ROLE OF METABOREFLEX

PEREZ-VALERA, M., CURTELIN, D., MARTIN-RINCON, M., PEREZ-SUAREZ, I., TORRES-PERALTA, R., CALBET, J.A.L., MORALES-ALAMO, D.

IUIBS University of Las Palmas de Gran Canaria, Spain

Introduction During sprint exercise pulmonary ventilation (VE) is dramatically increased, likely due to a strong activation of the central command. Consequently, the arterial CO₂ pressure is reduced what may cause lower cerebral blood flow (CBF) and oxygenation. When the sprint exercise is performed immediately after task failure, the PaCO₂ at the start of the sprint is even lower. Since metaboreflex activation increases VE, it could contribute to further reduce CBF and oxygenation. Thus, the aim of this study was to determine the effects of metaboreflex activation on CBF and oxygenation during sprint exercise. **Methods** Eleven young men (age: 23±3 yr; weight: VO_{2max}: 3.6±0.5 L/min, mean±SD) were studied on different days. NIRS optodes were used to measure frontal lobe oxygenation (FLO) and vastus lateralis oxygenation (VLO), and Doppler probes to assess bilaterally middle cerebral arteries velocities (MCAv). After warm-up, subjects performed a 10s isokinetic all-out sprint at 80 RPM (control sprint), followed by an incremental exercise test to exhaustion. At exhaustion, the circulation was occluded bilaterally (300 mmHg, Hokanson) during either 10 or 60 s. At the end of the occlusion the cuff was released at the same time the subjects performed another 10s isokinetic sprint. The same experiments were repeated without occlusion during the 10 and 60 s recovery periods. Results MCAv was reduced during the control sprints from 47.8±8.1 to 40.8±6.2 cm/s ($P<0.05$), FLO from 64±5 to 61.8±5.3% ($P<0.05$) and VLD from 73±5 to 56±6%. During sprint exercise at task failure MCAv and FLO were even lower, with this effect being more marked after the 60s recovery, coinciding with a lower PETCO₂ than during control sprints ($P<0.05$). Ischemic recovery prevented the reduction of MCAv. Sprint performance was reduced at task failure, but was higher after 60s of ischemic recovery than after 10s of ischemic recovery ($P<0.05$). However, greater recovery of performance was observed after 60s of open circulation recovery despite lower MCAv and similar FLO. **Discussion and conclusion** This study shows a reduction of CBF during sprint exercise and a small but significant reduction of frontal lobe brain oxygenation. This effect may be prevented by the application of ischemia at the end of and incremental exercise to exhaustion, despite greater reduction of PETCO₂ during the sprints after Ischemia. These findings suggest that task failure is not caused by a reduction of CBF or FLO. Moreover, ischemic recovery helps to maintain CBF despite a marked reduction of PETCO₂. Thus, the metaboreflex contributes to maintain CBF close to exhaustion. Granted by Cátedra Real Madrid-Univ Europea de Madrid (2015/04RM).

AN ACUTE BOUT OF COLD STRESS INCREASES CEREBRAL AUTOREGULATION IN HEALTHY INDIVIDUALS

MILLER, G.D., GEORGE, K.P., LOW, D.A., JONES, H.

Liverpool John Moore University

Introduction: Sufficient continuous cerebral blood flow (CBF) is imperative for appropriate neural function and is controlled via (i) blood (perfusion) pressure (BP), (ii) cerebral autoregulation (ability of the brain to control its flow independently of changes in BP) and (iii) local changes in carbon dioxide (CO₂) levels. Cold exposure increases CBF and may have favourable benefits on the maintenance of CBF under conditions that jeopardise/attenuate it, e.g., orthostatic stress (Wilson et al., 2002). Despite the seemingly beneficial effects of cold stress on CBF, our aim was to investigate if the underlying control mechanisms of CBF (cerebral autoregulation and CO₂ reactivity) are altered by an acute bout of cold stress. We hypothesised that a bout of cold stress would increase cerebral autoregulation. **Methods:** Following sample size estimation, CBF was quantified in the middle cerebral artery (MCA; Transcranial Doppler) in 12 individuals (32±16 yrs). Cerebral reactivity to CO₂ (rebreathing gas concentration of 5% CO₂) and cerebral autoregulation (manipulations of BP with squat-stand manoeuvres at 6 and 12 Hz·min⁻¹) were assessed while wearing a tube-lined suit perfused with 34°C water (thermoneutral) and with 12°C water to induce whole body skin surface cooling (cold). MCAv, end tidal partial pressure of CO₂ (PETCO₂), BP (Finometer) and skin (Tsk) and core temperatures (Tc) were measured throughout. CBF and BP during the squat-stand manoeuvres were analysed using transfer function analysis in the high, low and very low frequencies for gain, phase and coherence. Data were analysed using paired t-tests and presented as mean±SD. **Results:** Tsk was reduced by 5.5±1.4°C ($P\leq0.001$) and Tc was unchanged following skin surface cooling. Basal MCAv did not differ, PETCO₂ was lower (thermoneutral 38.6±2.6 vs cold: 37.7±4.7 mmHg $P=0.05$) and MAP higher (thermoneutral 82±5 vs cold: 87±5 mmHg; $P=0.002$) following cooling. At 6 Hz·min⁻¹ squat-stands coherence between MCAv and MAP in the low frequency domain was lower following cooling (thermoneutral: 0.84±0.07 vs cold: 0.75±0.10, $P=0.02$). At 12 Hz·min⁻¹ squat-stands phase was higher in the high frequency domain following cooling (thermoneutral: 105.2±12.7 vs cold: 114.8±10.9, $P=0.05$). Coherence was also lower in the very low and high frequency domains following cooling ($P=0.04$). There were negligible differences in the MCAv CO₂reactivity following cooling (thermoneutral: $r=0.84\pm0.10$ vs cold: $r=0.76\pm0.23$; $P=0.11$). **Conclusion:** These novel findings indicate that an acute bout of cold stress enhances the brains ability to autoregulate, thus maintain its own flow independent of BP. Cold exposure could possibly be used as a strategy to improve autoregulation in individuals with impaired cerebrovascular function. Wilson TE et al. 2002. JAP, 93, 85

Mini-Orals**MO-PM03 Ageing 1****MUSCULAR ACTIVIN RECEPTOR IIB EXPRESSION IS ASSOCIATED WITH DYNAPENIA, AGE AND BODY MASS**

HOFMANN, M., HALPER, B., OESEN, S., FRANZKE, B., STRASSER, E.M., WAGNER, K.H., WESSNER, B.

University of Vienna

Introduction During the ageing process strength and power decline more rapidly than muscle mass, whereby this decline is defined as 'dynapenia' [1]. Nevertheless, muscle mass is one of the main determinants of strength [2]. Therefore, many studies focused on the influence of hypertrophy and atrophy signals on muscle mass, but there is a lack of knowledge how these signals relate to the loss of muscle strength. The aim of this study was to investigate whether key members of the TGF-beta superfamily (activin A, activin receptor IIB (ActRIIB), growth differentiation factor-15 (GDF-15), myostatin, follistatin and Insulin-like growth factor-1 (IGF-1) differ between older women with or without signs of dynapenia. **Methods** In this cross sectional study, 38 women (69–92 years) were categorized into non- ($n=9$), mild ($n=17$) and severe ($n=12$) dynapenic groups based on cut-off levels for isokinetic peak torque of knee extension (PTE) as described previously [3].

Biopsies from m. vastus lateralis were obtained in a resting state. Total RNA was isolated by standardized procedures and mRNA of activin A, myostatin, GDF-15, ActRIIB, IGF-1 and follistatin were quantified by real-time RT-PCR using GAPDH for normalisation. In addition, body composition was determined by bioimpedance analysis. Differences between groups were detected by ANOVA followed by post-hoc analysis with Bonferroni correction. Results Severe dynapenic women were older ($p=0.004$, +8 years) and had lower body mass ($p=0.003$, -20 %) than non-dynapenic women. Most interestingly, ActRIIB expression was higher in severe ($p=0.002$, +88 %) and mild dynapenic ($p=0.023$, +76 %) as compared to non-dynapenic participants. Furthermore, ActRIIB mRNA expression significantly correlated positively with age ($p=0.535$, $p=0.001$) but negatively with PTE ($p=-0.485$, $p=0.002$), handgrip strength ($p=-0.603$, $p<0.001$), muscle mass ($p=-0.375$, $p=0.020$) and fat mass ($p=-0.379$, $p=0.019$). None of the other parameters were influenced by strength level. Discussion The findings from this study suggest that the loss of muscle strength during the ageing process is associated with changes in ActRIIB. Besides inducing atrophy signals, ActRIIB regulates key determinants of muscle energy metabolism endowing skeletal muscle with high oxidative capacity and low fatigability [4]. As both, endurance and strength are important for healthy ageing there is an urgent need to have a closer look on ActRIIB signaling in this context. THE WAY YOU SPEND YOUR SEDENTARY TIME ALSO MATTERS: AN ANALYSIS OF THE ASSOCIATION BETWEEN SEDENTARY TIME, SEDENTARY PATTERNS AND FRAILTY IN THE ELDERLY

MAÑAS, A.1, DEL POZO-CRUZ, B.2, MARTÍN-GARCÍA, M.1, MARÍN, J.3, GARCÍA-GARCÍA, F.J.4, GUADALUPE-GRAU, A.4, ARA, I.1

1: GENUD Toledo Research Group (Toledo, Spain), 2: Department of Exercise Sciences (Auckland, New Zealand), 3: GENUD Research Group (Zaragoza, Spain), 4: Hospital Virgen del Valle (Toledo, Spain).

Introduction Time spent in sedentary activities has been associated with negative health outcomes in older people (Stamatakis et al., 2012). However, the role that sedentary behaviour patterns play on health has been scarcely investigated in this population group. The ability of performing well in the diverse activities of the daily life is partially determined by the level of frailty (García-García et al., 2014). However, no studies have been conducted yet to clarify the role of sedentary behaviour on frailty. We therefore examined the associations of daily sedentary time (DST) and sedentary patterns (SP) with frailty in elderly. Methods A triaxial accelerometer (ActiGraph, ActiTrainer 3X) was used to determine the DST and SP in 234 males and 285 females aged between 67 and 95 years in the ETES study (Carcaillon et al., 2012). Using the z-scores of the number of 10-min sedentary behaviour bouts and the average duration of those bouts, a SP composite score was created, according with other previous studies (Artero et al., 2011). Frailty was calculated using the Frailty Trait Scale (FTS). Different linear regression models were performed in order to analyse the associations of DST and SP with FTS. All models were adjusted for gender, age, educational level, Charlson index, Katz index, Mini Mental State Examination, and number of drugs. Results After adjusting for the mentioned potential confounders, a statistically significant association was found between SP and FTS (B [95%CI]: 1.573 [0.364, 2.781], $\beta=0.104$, $p<0.001$). DST was also significantly associated with FTS (B [95%CI]: 0.015 [0.002, 0.028], $\beta=0.095$, $p<0.001$). Discussion Both sedentary patterns and daily sedentary time are associated with frailty in older people from the ETES study. Our results suggest that interventions should not only be focused on reducing the total time spent in sedentary activities but also on how that time is accumulated in order to prevent frailty in elderly people. MENTAL SIMULATION OF LOCOMOTOR TASKS IMPROVES REHABILITATION OUTCOME IN ELDERLY ADULTS AFTER HIP SURGERY

MARUSIC, U.1, TAUBE, W.2, MORRISON, S.A.1,3, SIMUNIC, B.1, PARAVLIC, A.1, BIASUTTI, L.4, GRASSI, B.4, PISOT, R.1

1: University of Primorska (Slovenia), 2: University of Fribourg (Switzerland) 3: Institute for Clinical Neurophysiology, UKC (Slovenia), 4: University of Udine (Italy)

Introduction: Prolonged immobilization and inactivity after injury and/or surgery may lead to serious motor/cognitive dysfunction, especially in older adults. Previous work has revealed that mental simulation such as action observation (AO) or motor imagery (MI) activates similar brain regions as actual motor execution and increases corticospinal excitability (Wright, Williams & Holmes, 2014); mechanisms that may accelerate (re-)learning and rehabilitation of motor skills (e.g. Mulder, 2007). This study aimed to determine whether the combination of AO and MI could positively affect locomotor performance and prefrontal cortex (PFC) oxygenation when tested 60-days post hip surgery. Methods: Of an initial 405 participants (database of the Orthopaedic Hospital Valdoltra (Slovenia)), 26 eligible patients were screened (e.g. no significant co-morbidities) of whom 21 successfully completed all study measurements. They were randomly split into 2 groups: Control (CON; N=11; 63±6y) which followed a standard rehabilitation protocol, and Intervention (INT; N=10; 64±4y) which received additional cognitive interventions (AO+MI of locomotor tasks) for 30 min/day in the hospital, then 3x/week in their homes, for a period of 2 months. Gait and postural control during dual-tasking (DT; balancing/walking while subtracting by threes), Timed Up and Go (TUG) and Four Step Square Test (FSST) were measured before and 60-d after hip surgery. Additionally, PFC (O2Hb and HHb levels, by continuous-wave near-infrared spectroscopy (NIRS)) was assessed during postural/DT control. Interaction effects (groups x time) were evaluated using a 2x2 mixed ANOVA. Results: At baseline, both groups were matched in their cognitive and functional abilities ($p>0.341$). There were significant interactions for TUG ($p=0.045$), FSST ($p<0.001$), gait performance ($p=0.028$), and mental arithmetic while DT ($p=0.042$) exhibited better outcomes for the INT vs. CON. No interactions were found for NIRS ($p>0.221$) and balance ($p>0.229$) parameters. Discussion: These results demonstrate that mental simulation provides positive outcomes on motor-cognitive measures after hip surgery in elderly people. Interestingly, all parameters associated with locomotor activities improved significantly, whereas balance skills were not affected by AO+MI, demonstrating the specificity of the training intervention. From a functional perspective, it is positive that cognitive performance during DT-walking improved, although these adaptations were not accompanied by changes in PFC. Overall, utilizing AO+MI training during rehabilitation is advised, especially when physical practice is constricted or not possible. References: Wright DJ, Williams J, Holmes PS. (2014). EFFECTS OF INCREASED DAILY PHYSICAL ACTIVITY ON BRAIN-DERIVED NEUROTROPHIC FACTOR, SEROTONIN AND OXIDATIVE STRESS MARKERS IN OLDER ADULTS

TAKAHASHI, M.1, ARAO, T.2, KIM, H.K.2, TSUBOSAKA, M.1, MIYASHITA, M.3, SHIBATA, S.1

1:Waseda University, 2:Waseda University, 3:Tokyo Gakugei University

Introduction Brain-derived neurotrophic factor (BDNF), serotonin and oxidative stress are associated with the development of depression and dementia. Although many studies have shown that exercise training improves depression, little is known about the effectiveness of daily physical activity on depression biomarkers in older adults. The purpose of this study was to investigate the effects of increased daily physical activity during the intervention period for 8 weeks on levels of BDNF, serotonin and oxidative stress markers in older adults. **Methods** Thirty-eight healthy postmenopausal women (71 ± 1 years old [mean \pm SD]) were randomly assigned to one of the following two groups: control (C, n=19) and active (PA, n=19). The participants in the PA group were asked to increase their physical activities above their usual lifestyle levels for 8 weeks. They were free to decide the duration and intensity of their chosen activities. The participants in the control group maintained their usual lifestyle for 8 weeks. All participants were asked to wear a uniaxial accelerometer during the 8-week period. Blood samples were obtained at the baseline and the end of the intervention. **Results** After the intervention for 8 weeks, the step counts of the participants in the PA group have increased from 6043 ± 696 (at baseline) to 7978 ± 869 steps/day ($P < 0.05$). The serum concentrations of BDNF and serotonin have significantly increased in the PA group ($P < 0.05$) but not in the C group after 8 weeks compared with the baseline values. The serum concentrations of derivatives of reactive oxygen metabolites and biological antioxidant potential did not change after intervention in either group. **Discussion** These findings seem to suggest that promotion of daily physical activity in older adults is effective for improving the function of nervous and endocrine system without any change in oxidative stress. **References** Rawdin B.J. et al. EFFECT OF AGING ON SEX DIFFERENCES IN FAT OXIDATION.

TABATA, H.1, KIM, H.K.1, KONISHI, M.2, ANDO, K.1, XIANG, M.1, SUZUKI, K., HIGUCHI, M.2, SAKAMOTO, S.2

Introduction Fat oxidation rate during exercise observed interindividual variation. Previous studies have suggested that physical activity, cardiorespiratory fitness, and sex are determinants of fat oxidation rate (Venables et al, 2005). Although young women have greater fat oxidation during exercise than young men (Chenevière et al., 2011; Horton et al., 1998), it is unclear whether these sex differences are applied to elderly. The basal metabolic rate decreases with increase in age, and women experience menopause during middle age. Therefore, the aim of this study was to investigate the influence of aging on sex differences in fat oxidation rate. **Methods** 236 healthy men and women (161 men and 75 women, 40-87 years) who participated "Waseda Alumni's Sports, Exercise, Daily Activity, Sedentarieness Health Study" from March to December 2015 performed a graded exercise test on a cycle ergometer. Peak oxygen uptake (VO_{2peak}), maximal fat oxidation (MFO), and the intensity at which MFO occurred (Fatmax) were measured with indirect calorimetry during exercise. These data were categorized into 6 groups by sex and age (40's: 40-49, 50's: 50-59, and over 60 years: ≥ 60 years). Comparison of mean values of the groups was performed using two-way analysis of variance with Bonferroni post-hoc test. Results VO_{2peak} values were significantly higher in men than in women and decreased with increase in age in both, men and women; the VO_{2peak} values for subjects in their 40's were significantly higher than those for subjects in their 50's and those over 60 years of age. MFO was not significantly different across sex and age. Fatmax values was significantly higher in men than in women. Fatmax values increased with age, and were significantly higher for subjects in their 50's than for those in their 40's. Fatmax values were significantly higher in subjects older than 60 years of age than in subjects in their 40's and 50's; this was true for both, male and female subjects. **Discussion** There were no sex differences in fat oxidation rate in middle-aged elderly people. Given it is well documented that women have greater fat oxidation rate than men in young people, fat oxidation rate may alter in the period from young age to middle age. **References** Chenevière X, Borrani F, Sangsue D, Gojanovic B, Malatesta D. INFLUENCE OF ENERGY COST OF WALKING ON GAIT SPEED AND PHYSICAL ACTIVITY LEVEL IN ELDERLY WOMEN

CIPRANDI, D.1,2, ZAGO, M.1, BERTOZZI, F.2, SFORZA, C.1, GALVANI, C.3

University of Milan

1: Laboratorio di Anatomia Funzionale dell'Apparato Locomotore, Dipartimento di Scienze Biomediche per la Salute, Università degli Studi, Milano, Italia, 2: Corso di Laurea in Scienze Motorie, Università Cattolica del Sacro Cuore, Milano, Italia, 3: Laboratorio di Fisiologia Sperimentale, Dipartimento di Psicologia, Università Cattolica del Sacro Cuore, Milano, Italia **INTRODUCTION** It has been demonstrated that the age-associated increase in energy cost of walking (CW) may result in a slowing of gait speed (Schrack 2012). Physical activity level (PA) also declines with age (Troiano 2008). However, in our knowledge, no studies have examined the influence of CW on PA habitually maintained. Therefore, the aim of this study was to define the influence of CW on both gait speed and PA. **METHODS** 42 healthy young (YA) and older (OA) women (YA: age, 22.6 ± 2.9 yr; BMI, 22.5 ± 2.6 kg/m²; OA: age, 68.3 ± 3.3 yr; BMI, 26.1 ± 3.0 kg/m²) were recruited in the study. NetCW was analysed with indirect calorimetry during treadmill walking at different speeds and calculated subtracting resting metabolic rate measured during standing from gross metabolic rate. Gait speed, defined as the preferred walking speed (PWS) of the subject, was measured as the time taken to walk the middle 10m of 14m. To assess PA, subjects wore a multisensor activity monitor for a whole week, inferring time spent in moderate to vigorous PA (MVPA>3METs). MVPA were analysed in bouts of at least 10 consecutive minutes (MVPAbout) and in overall minutes (MVPAtot). **RESULTS** No significant differences were found between the two groups for NetCW at the speed closest to the PWS, the gait speed and both MVPAbout and MVPAtot (YA: NetCW, 2.89 ± 0.38 J/kg/m; PWS, 5.0 ± 0.7 km/h; MVPAbout, 28 ± 29 min/day; MVPAtot, 61 ± 52 min/day; OA: Net CW, 3.07 ± 0.63 J/kg/m; PWS, 4.8 ± 0.5 km/h; MVPAbout, 29 ± 42 min/day; MVPAtot, 61 ± 64 min/day). MVPAbout was significantly lower than MVPAtot for both groups ($p < 0.0001$) and only MVPAtot exceeded current PA guidelines ($p = 0.001$). Regression analysis, adjusted for age and BMI, revealed that neither PWS nor PA were related to a lower NetCW at the speed closest to the PWS. Only fastest walkers had higher daily level of PA independently of age ($r = 0.376$, $p = 0.013$; $r = 0.324$, $p = 0.035$ for MVPAbout and MVPAtot, respectively). **DISCUSSION** In our study elderly women did not show a decrease of PWS and PA due to age. Moreover, an equivalent NetCW of walking was found in healthy elderly women when compared to younger counterparts while walking at their PWS. The present results showed that in healthy elderly women CW is not affected by age allowing a

high PWS and an elevated level of PA. REFERENCES Schrack JA. (2012). J Am Geriatr Soc, 60(10), 1811-1816. Troiano RP. (2008). Med Sci Sports Exerc, 40(1), 181-188.

ASSOCIATION BETWEEN GRIP STRENGTH AND FALLS WITHIN THE LAST 12 MONTHS IN OLDER ADULTS IS MEDIATED BY UNBALANCE: RESULTS FROM THE KORA-AGE STUDY

STRASSER, B.1, ARVANDI, M.2, VOLAKLIS, K.3, MATTEUCCI GOTHE, R.2, SIEBERT, U.2, LADWIG, K.H.4, GRILL, E.5, HORSCH, A.3, LAXY, M.4, PETERS, A.4, THORAND, B.4, MEISINGER, C.4

Biocenter, Division of Medical Biochemistry

Introduction: Impaired muscular strength is strongly related to activity limitations and physical disability in middle-aged and aged individuals. However, studies evaluating the relation between muscular strength and risk of falling in older adults whilst taking the indirect effect of potential mediators into account are lacking. Thus, the objective of this study was to examine this association in a population-based study. Methods: Data originate from the KORA (Cooperative Health Research in the Region of Augsburg)-Age study (Peters et al., 2011). 1079 individuals (mean age \pm SD: 76 \pm 7 years) were enrolled. Handgrip strength was measured using the JAMAR Dynamometer. Multivariable logistic regression analysis was used to determine adjusted odds ratios (OR) with 95% confidence intervals (95%CI) for falls within the last 12 months. Potential confounders were pre-selected based on literature and expert opinion. Path analysis was used to assess the indirect effect of potential mediators on the association between grip strength and falls. Results: The risk for falls within the last 12 months was reduced by 3% (OR (95%CI): 0.97 (0.95-0.99)) per one kilogram increase in maximum grip strength after adjusting for significant confounders (i.e., age, nutritional status, number of prescribed drugs, and level of physical activity). Higher grip strength was significantly associated with lower risk of falls (0.96 (0.94-0.98)) and lower unbalance level ($p<0.0001$). The indirect effect of grip strength through the mediator variable unbalance was statistically significant ($p=0.002$). The significant association between grip strength and falls continued to exist after controlling for the mediator unbalance (0.97 (0.95-0.98)). Conclusion: Muscular strength is inversely and independently associated with falls in the old age. This association is partly mediated by unbalance. However, balance itself may affect muscle strength through transfer effects. In the LiFE approach, which embeds strategies to improve balance, ankle strength, a prime factor for postural stability, significantly improved compared with a structured control program (Clemson et al., 2012). Thus, the integration of both balance and muscle-strengthening exercises into daily life activity may reduce the rate of falls in older people. References: Clemson L et al. (2012). BMJ, 345, e4547. EFFECTS OF A BRISK WALKING PROGRAM AND 2-YEAR FOLLOW-UP ON THE SARCOPENIC RISK PROFILE IN SEDENTARY OBESE POSTMENOPAUSAL WOMEN

GARNIER, S.1, JOFFROY, J.1, JOANISSE, D.R.2, AUNEAU, G.1, MAURIÈGE, P.2

Université Paul Sabatier

Introduction Although the impact of walking on subjects' cardiometabolic risk profile has been largely investigated (Asikainen et al., 2004, Mosca et al., 2007; Tudor-Locke et al., 2014), no study has examined yet the influence of a brisk walking program on the sarcopenic risk profile of sedentary and moderately obese, postmenopausal women. Aim of the present study was to examine the effects of a 4-month brisk walking program on the sarcopenic risk profile, and its impact two years after the intervention. Methods 67 initially sedentary and overweight-to-obese (mean body mass index, BMI = 30,0 \pm 4,7 kg/m²) postmenopausal women (60,9 \pm 6,2 yr-old) were subjected to a 4-month walking program (3 sessions of 45 min each/week at 60 % of their heart rate reserve), while 19 women of similar age (60,6 \pm 5,3 yr-old), adiposity (BMI = 29,9 \pm 5,6 kg/m²) and menopausal status remained inactive during the same period. Following measurements were performed before and after the 4-month study-period, as well as two years later in both groups: CRF assessed by the 2-km walking test and estimated VO₂ max then calculated (Laukkanen et al., 1993), height, weight (BMI calculated) and waist circumference measured using standardized procedures, as well as fat mass and lean body mass determined by bioelectrical impedance (Roussel et al., 2009; Garnier et al., 2013) and lean body mass index (LBMI) calculated (Heber et al., 1996). Results Four months later, CRF increased, body weight and fat mass decreased ($p<.0001$) in the walking group exclusively, while LBMI was maintained in the two groups. Two years later, increase in CRF and body weight and fat mass losses were maintained ($p<.01$) in the 67 women who completed the study, while LBMI remained unchanged in the two groups. Discussion The low sarcopenic risk profile was maintained after this 4-month walking program and two years later, despite the body weight reduction. However, more studies are needed to examine whether age may influence the evolution of LBMI, irrespective of women's menopausal status. References Asikainen TM, et al. (2004) Sports Med, 34, 753-778. RELIABILITY OF ADDUCTORS/ABDUCTORS ISOKINETIC TESTING AND ITS RELATIONSHIP TO ICE HOCKEY SPRINT PERFORMANCE

SCHAFFNER, K.1, BESSON, C.2, GREMION, G.2, DEGACHE, F.1,3

CHUV Lausanne

Introduction Skating performance is a key parameter of ice hockey performance. Adductors/abductors muscles are highly involved in this locomotion pattern and are poorly investigated in the literature. The aims of this study are: 1) to evaluate the reliability of an adductors/abductors isokinetic test, 2) to compare ice hockey players results to a non-skating sport population, 3) to analyse the relationships between isokinetic test results with off-ice and on-ice tests in elite ice hockey players. Methods In order to evaluate reliability, 12 controls performed two side-lying isokinetic hip tests separated by 6.9 \pm 0.7 days. Another group of 9 elite ice hockey players performed an

isokinetic hip test 5.6 ± 0.7 days after performance tests (Countermovement jumps, 36.5m off-ice and on-ice sprints). All of the isokinetic tests were analysed with gravity correction. Results The ICC range of the control group were $0.71-0.95$, with 75% of the values being above 0.8 (moderate to high) showing a good reliability. The ice hockey players showed a significant difference on adductors isokinetic strength at every speed vs. control group values. No differences were found on the abductors values between the two groups. A significant correlation was found between isokinetic muscle strength of right adductors at $120^\circ/\text{s}$ in concentric and skating time at 36.5 meters (CC: $-0.78 / p = 0.01$). There is also a relationship between off-ice and on-ice sprints (CC: $0.78; p = 0.005$). As well, the vertical jumps and the on-ice sprints were correlated (CC: $-0.603; p = 0.05$). Discussion Isokinetic hip testing in side-lying position seems to be reliable in a better way than previously described (Emery et al., 1999). Ice hockey players develop significantly higher adductors strength compared to a non-skating sport population, rejoining results from a similar investigation (Kea et al., 2001). Adductors strength seems to be linked with on-ice sprint performance in elite ice hockey players. Finally, there is a relationship between off-ice countermovements jumps and 36.5m sprints with on-ice 36.5m sprint performance, confirming relationships between off-ice and on-ice performance seen in previous studies (Janot et al., 2015, Mascaro et al., 1992) References Emery CA, Maitland ME, Meeuwisse WH. LOW LOAD BENCH PRESS AND PUSH UP WITH SIMILAR INTENSITY INDUCE COMPARABLE MUSCLE HYPERSTROPHY AND STRENGTH GAIN IN UNTRAINED MEN

KIKUCHI, N.1, SAITO, M.2, OKUYAMA, M.3, NAKAZATO, K.4

Nippon Sport Science University

1: Sports Training Center, Nippon Sport Science University. (Tokyo, Japan), 2: Department of Exercise Physiology, Nippon Sport Science University. (Tokyo, Japan), 3: Graduate School of Health and Sport Science, Nippon Sport Science University. (Tokyo, Japan) Introduction The push-up can be performed without any additional tools and the intensity can be altered with several variations, thus making it suitable for almost every level of fitness. The purpose of present study was to investigate the effect of push up training with similar load of 40% 1 repetition maximal (RM) bench press on muscle hypertrophy and strength gain in untrained men. Methods Eighteen untrained men (age; 20.2 ± 0.73 years, age range; 19-22 years, height; 169.8 ± 4.4 cm, weight; 64.5 ± 4.7 kg) volunteered to participate in this study. Subjects were randomly assigned to the experimental group as follows: 1) bench press exercise with 40%1RM (BP group, n = 9), 2) push up with adjusted their position (e.g. kneeling) to be the same load of 40%1RM of bench press (PU group, n = 9) in 8 weeks. We measured bench press 1RM, maximal repetition at 50%1RM. Three sites of muscle thickness (MT), biceps (BB), triceps (TB) and pectoralis major (PM), and power out put performance (medicine ball throw) were also measured. All parameters were assessed before and after the training periods. Results Significant increases in 1RM and MT (TB and PM) were observed in BP group (1RM; 60.0 ± 12.1 kg to 65.0 ± 12.1 kg, $p < 0.01$, MT-TB; 26.3 ± 3.7 mm to 27.8 ± 3.8 mm, $p < 0.01$, MT-PM; 17.0 ± 2.8 mm to 20.8 ± 4.8 mm, $p < 0.01$) and in PU group (1RM; 61.1 ± 12.2 kg to 64.2 ± 12.5 kg, $p < 0.01$, MT-TB; 27.7 ± 5.7 mm to 30.4 ± 6.6 mm, $p < 0.01$, MT-PM; 17.0 ± 2.8 mm to 20.8 ± 4.8 mm, $p < 0.01$). Significant increase in MT-BB was observed only in BP group (28.4 ± 3.3 mm to 31.5 ± 3.7 mm, $p < 0.01$). There is no significant increase in power out put performance and muscle endurance capacity in both groups. Discussion This is the first investigation for compare muscle hypertrophy and strength gain between low intensity bench press and push up training performed with similar intensity, rest interval and speed of movement. Our result suggested that push up exercise with similar load of 40%1RM bench press is effective in muscle hypertrophy and strength gain as well as bench press exercise in 8 weeks training. SCAPULAR MUSCLE ACTIVITY IN FEMALE VOLLEYBALL PLAYERS WITH STATIC SCAPULAR ASYMMETRY DURING CLOSED CHAIN EXERCISES

KARAGIANNAKIS, D., ATHANASOPOULOU, E., ATHANASOPOULOS, S., MANDALIDIS, D.

National & Kapodistrian University of Athens

Introduction Resting scapular asymmetry is a common postural deviation in overhead athletes (Burkhart et al., 2003; Oyama et al., 2008). It has been proposed that possible alterations in the EMG activity of scapular muscles, due to asymmetric position of the scapulae, may alter their kinematics leading to shoulder pathology (Burkhart et al., 2003). The aim of the current study was to identify alterations in the EMG activity of the scapular stabilizers in healthy volleyball female athletes with static scapular asymmetry. Methods Static scapular position with regard to scapular protraction (difference between scapulae spinal's root-to-midline horizontal distances) and depression (vertical distance between spinal's root-to-midline horizontal projections of both scapulae) was determined in 46 professional female volleyball players. Twenty two players with protraction ($x \pm SD = 0.8 \pm 0.5$ cm) and depression ($x \pm SD = 1.1 \pm 0.6$ cm) of the dominant scapula (most common scapular malpositioning) completed two upper extremities closed chain exercises on a stable (floor) and an unstable surface (BOSU platform). The EMG activities of upper trapezius (UT), middle trapezius (MT) and serratus anterior (SA) were recorded bilaterally and reported as the geometric mean (95% CI) of the percentage of each muscle's MVC. Results Our findings revealed no significant differences between the dominant and non-dominant sides with regard to the EMG activity of UT [15 (12-19) vs. 14 (11-17) %MVC], MT [10 (9-12) vs. 12 (10-14) %MVC] and SA [61 (49-77) vs. 70 (55-88) %MVC], during knee push-ups with hands on the floor. Similarly, the differences between the dominant and non-dominant sides for the EMG activity of UT [19 (15-24) % vs. 16 (13-21) %MVC], MT [11 (9-13) vs. 12 (10-15) %MVC] and SA [56 (45-69) vs. 69 (56-86) %MVC], were not significant during knee push-ups with hands on the BOSU platform. Discussion Based on the findings of the present study, bilateral EMG activity of scapular stabilizers were not affected by resting scapular asymmetry in volleyball athletes. Although not significant, the lower SA activation of the dominant side compared to the non-dominant side, in conjunction with the relatively similar bilateral activation of UT and MT could probably predispose these athletes in poor scapular stabilization during closed chain exercises. Bilateral differences in the EMG activity of scapula stabilizers could be more pronounced in overhead athletes with greater levels of scapular asymmetry. References Burkhart S, Morgan C, Kibler WB. Introduction: Range of Motion (ROM) can be manipulated in resistance training programs in order to improve strength gains and sports performance. To the best of our knowledge, only two studies (Bloomquist et al. 2013; McMahon et al. 2014) have shown that different ROM training might lead to specific adaptations on muscle size, muscle force and fascicle geometry. However, in these studies, the training volume was not equalized, which might have affected the final results. Therefore, the aim of this study was to determine the effect of a 15-week partial ROM knee extension strength training on the vastus lateralis (VL) muscle architecture and mechanical properties, when the time under tension (TUT) was equalized. **Methods:** Nineteen male physical education students were randomly distributed to a control (CG; n = 8) or training (TG; n=11) group. In the TG the subject's legs were also randomly selected to be trained with full ROM (FULL) or partial ROM (PAR). They performed isokinetic knee extensors concentric training on a isokinetic dynamometer (Biodex System 3 research, USA) for 15 weeks with 3 sessions per week, with either a FULL (100° of knee flexion to 0°) and PAR (60° of knee flexion to 0°) ROM. Training volume between conditions was equalized based on TUT. The VL muscle thickness (MT), fascicle length (FL) and pennation angle (PA) were assessed for both thighs by B-mode ultrasonography at rest and during maximal isometric knee extension contractions (MVCs) at fifteen knee joint angles, ranging from 30 to 100° of knee flexion (full extension=0°). VL fascicle force was calculated from MVCs with superimposed stimuli, accounting for the VL moment arm length, muscle architecture, and antagonist co-contraction. **Results:** MT, PA, and maximal fascicle force (MFF) increased significantly from baseline to post-training in both training groups ($p<0.001$). The changes ($\Delta\%$) were respectively for FULL and PAR, MT: $8.4 \pm 2.9\%$ and $6.7 \pm 3.0\%$; PA: $9.5 \pm 2.4\%$ and $12.2 \pm 2.4\%$; MFF: $28.8 \pm 19.5\%$ and $19.0 \pm 10.8\%$. Significant differences between FULL and PAR were found only on FL, which increased $4.9 \pm 1.9\%$ ($p<0.001$) in FULL group, with no changes in PAR group (Δ : $-1.1 \pm 3.4\%$, n.s.). The PAR group showed a specific effect on the VL force-length adaptations, presenting higher force levels at the trained angular positions. **Discussion:** The morphological and mechanical muscle adaptations seem to be influenced by the ROM of strength training exercises. When the ROM stimulates large muscle amplitudes, the fascicle length tends to increase. Conversely, when the amplitude of muscle action is restricted to reduced muscle lengths we are promoting identical pennation angles but specific force adaptations. References Bloomquist, K., H. Introduction The number of repetitions determines resistance-training volume, and is influenced by the time spent for eccentric (ECC) and concentric (CON) contractions in a set. A previous study (1) showed that the maximum number of repetitions in leg extension was greater when a longer duration (5 s) was set for ECC than CON. However, the effect of ECC and CON duration on the maximum repetitions in squat exercise is unknown. The present study compared two protocols in which the duration of the ECC and CON phase in squat was different on the maximum repetitions and muscle damage. **Methods** Ten physically active male students (age: 20.6 ± 1.1 y, height: 172.8 ± 3.5 cm, body mass: 63.8 ± 3.8 kg, squat 1RM: 103.5 ± 12.0 kg) participated in this study. After a familiarisation session in which a parallel back squat exercise (2 s for CON and 2 s for ECC) was performed as many repetitions as possible for 3 sets, (a) 2 s for CON and 4 s for ECC (C2E4), and (b) 4 s for CON and 2 s for ECC (C4E2) with a 3-min rest between sets were performed in a randomised order separated by a week. For each protocol, the number of successful repetitions in each set over 3 sets of the squat at 75% 1RM was recorded, and rate of perceived exertion (RPE) after each set was assessed. Blood lactate (BLa) was measured before and 5, 10, and 15 min post-exercise. Maximal voluntary contraction strength of knee extension (MVC) was measured before, immediately after and 1 day after exercise, and muscle soreness (SOR) was assessed by a 100-mm visual analogue scale before and 1 day after exercise. Results Average RPE (17.9 ± 0.8 vs 17.8 ± 0.8) and peak BLa (6.7 ± 0.9 , vs 7.5 ± 1.0 mmol/L) were similar between C2E4 and C4E2. The number of repetitions was greater ($P<0.05$) for C4E2 (13.3 ± 3.6) than C2E4 (10.6 ± 2.0) in the 1st set only, and decreased ($P<0.05$) in the 2nd (8.3 ± 1.5 , 7.9 ± 2.2) and 3rd sets (6.5 ± 1.4 , 6.2 ± 1.7) similarly. MVC decreased by 17% immediately after and 4% at 1 day after exercise ($P<0.05$), and minor SOR developed (27 ± 16 mm) without a significant difference between C2E4 and C4E2. **Discussion** Contrary to the previous study (1), the longer ECC did not result in greater number of repetitions in the present study. This might be due to a difference in exercise (leg extension vs squat) and the time ratio (1:5 vs 2:4). The difference in the repetitions between C2E4 and C4E2 was evident in the 1st set only, and muscle damage was minor and not different between conditions. These results suggest that the modulation of the ECC and CON phase duration in squat exercise has minimal effects on performance and muscle damage. Reference 1) Goto et al. ACID-BASE RESPONSES DURING A COMBINED AEROBIC AND CIRCUIT RESISTANCE TRAINING PROTOCOL

ESTEVES, N.K., PEINADO LOZANO, A.B., CUPEIRO, R., BUTRAGUEÑO, J., PEINADO, P.J.B.

1: Brunel University (London, UK); 2: UPM (Madrid, Spain)

Introduction Resistance training produces a number of acute and chronic adaptations in the musculoskeletal, nervous, cardiovascular, endocrine and immune systems (Saikko, 2015). The aim of this study was to investigate the acid-base responses to three different Circuit Weight Training (CWT) protocols in moderately active individuals. **Methods** Twenty-four healthy participants (21.3 ± 2.9 years; 68.8 ± 10.3 kg) non-smoking and moderately active individuals completed three CWT sessions on separate occasions. These consisted of machine weights circuit (MC), free weights circuit (FW), and combined aerobic and machine weight circuit (CAM). All circuits had the same duration in time, number of exercises and targeted the same muscle groups. Before commencing the CWT protocols, participants completed a Wingate (WG) and VO₂Max incremental test (VM) on different days. Blood samples were taken post test/circuit at 0min, 3min and 5min, measuring pH level, concentration of lactate (La-), Bicarbonate (CHCO₃-) and standard base excess (cBase[Ecf]). Results pH measures were significantly higher at 0min for CAM vs the rest of the tests; CAM continued to have greater values than WG at 3min, and than MC and FW at 5min. La- measures were significantly lower at 0min for CAM vs MC, FW and WG vs FW: at 3min for CMA vs VM, MC:

5.69 ± 0.48 vs 9.22 ± 0.50 , 10.54 ± 0.89 ; at 5min for CAM vs VM, WG, MC, FW: 5.04 ± 0.48 vs 9.47 ± 0.65 , 9.70 ± 0.55 , 10.30 ± 0.77 , 8.76 ± 0.74 . cHCO₃- measures were significantly higher at 0min for WG vs VM, MC, CAM, FW: 19.53 ± 0.64 vs 14.56 ± 0.45 , 15.19 ± 0.70 , 16.82 ± 0.74 . cBase[Ec] measures were significantly higher at 0min for WG vs VM, MC, CAM, FW and CAM vs FW: -3.94 ± 0.70 vs -10.57 ± 0.63 , -11.44 ± 0.94 , -7.20 ± 0.73 , -8.76 ± 0.82 ; at 5mins for CAM vs VM, WG, MC, FW: -7.02 ± 0.70 vs -14.32 ± 0.52 , -11.65 ± 0.67 , -12.62 ± 0.89 , -10.16 ± 0.89 . Discussion Taken together, our findings indicate that CAM leads to higher levels of pH, cHCO₃-, cBase[Ec], and lower levels of La-. This suggests that in comparison with CWT and tests, it reached the lowest level of acidosis. This is most likely due to the aerobic component of CAM; thus allowing acid-base regulation to reoccur and homeostasis to be reached. Therefore, CAM would be the most beneficial CWT in the construction of a resistance training program where a high anaerobic capacity is not required. References Saikko, V. (2015). SELECTIVE RECRUITMENT OF DIFFERENT MUSCLE GROUPS USING AN ADJUSTABLE INNOVATIVE NON-MOTORIZED TREADMILL

BENVENUTI, P.1, ZANUSO, S.2, MARCOLIN, G.3, NARDON, M.3, PAVAN, P.3, PETRONE, N.3

1: University of Verona (Italy), 2: University of Greenwich (UK), 3: University of Padova (Italy)

Introduction In sports and exercise, treadmills are a widely used device. However, it is rare to use a traditional treadmill to activate the upper body. Equipped with an adjustable resistance and upper limb support for both pushing and pulling exercises the Skillmill (SKM), a non-motorized, innovative treadmill made by Technogym, was evaluated in the present study assessing its ability to recruit multiple muscle groups. The aim of the study was to assess the muscle activation of healthy males when performing ten different exercises on the SKM. Methods Eight healthy male subjects with similar levels of fitness participated. Each subject was asked to perform the following exercises: a 6 km/h walk (W), a 12 km/h run (R) and sprint (S) at maximal speed, a resisted walk at 6 km/h (RW), side shuffle (both legs leading) (SSR, SSL), galloping with a resisted harness, assessing both legs (GR, GL) and pushing against the front handle in a high or low grip (PH, PL). Surface EMG of 12 muscles on right side of each subject were investigated, applying 2 pre-gelled bipolar electrodes on the belly of each muscle: Tib. Ant. (TA), Gastr. Med. (GM), Vastus Med. (VM), Biceps Fem. (BF), Rectus Fem. (RF), Gluteus Max. (GLM), Rectus Abd. (RA), Adductor (AD), Erector Spinae (ES), Pect. Major (PM), Lat. Dorsi (LD), Triceps Brach. (TB). The kinematics data was collected by means of an optoelectronic system (BTS Bioengineering), using 12 reflective markers placed in specific bony landmarks. EMG signals were rectified, integrated with a moving window of 200 ms, filtered at 6 Hz and normalized to the gait cycle. Following this, an average signal over 5 consecutive cycles was concluded, defined between two consecutive right heel strikes. Results Sprinting on the SKM resulted in a maximized average of the cycle activation of GM, BF and GLM; when sprinting against a resistance and pushing against a low handle (PL) at a similar intensity, the activation of VM and RF of the forward leg was significantly increased; walking sideways highly activated the ES, whereas AD did not show any noticeable activity. Pushing on high grips (PH) activated mainly the PM and TB, however a greater recruitment of those muscles occurred when galloping and sprinting. Discussion The results of the study highlights the possibility of recruiting differently muscle groups at high intensities on a non-motorized treadmill equipped like the SKM with front handles and restraints, as well as rear support for belt or harness running. EARLY MECHANICAL RESPONSES OF THE PATELLAR TENDON TO SUBMAXIMAL ECCENTRIC RESISTANCE TRAINING IN YOUNG INDIVIDUALS

QUINLAN, J.I.1, FRANCHI, M.V.1, PHILLIPS, B.E.1, GREENHAFF, P.2, SZEWCZYK, N.1, ATHERTON, P.J.1, SMITH, K.1, MAGANARIS, C.N.3, NARICI, M.V.3

(1) University of Nottingham, (2) University of Nottingham (3) Liverpool John Moores University

Tendon tissue is known to adapt to resistance exercise interventions by increasing in biomechanical stiffness (1,2). While the majority of literature investigates adaptations pre and post intervention, typically over 8 weeks, previous research has demonstrated that resistance training results in morphological changes in muscle as early as 10 days (3). One would assume that following muscular hypertrophy, the corresponding tendon must also adapt in order to maintain an effective muscle-tendon unit. However, any early tendinous adaptations to RET (i.e. during the first weeks) have not been studied. We have therefore, undertaken a study to map the temporal responses of tendon tissue to resistance exercise. We recruited 6 young males (27.5 ± 6 yrs) for a 4-weeks resistance exercise intervention. Eccentric training took place 3x week upon a leg press, consisting of 4 sets of 12 repetitions at 60% 1-RM. Ultrasound-based measurements of patellar tendon stiffness and measurements of MVC and rate of torque development (RTD) between 0-50ms, were taken every 2 weeks. Patellar tendon stiffness showed a trend to increase from week 0 to week 2 (1376 ± 139 N/mm vs 1558 ± 163 N/mm, $P=0.070$) and was significantly increased by week 4 (1376 ± 139 N/mm vs 1950 ± 214 N/mm, $P=0.007$). Similarly, RTD showed a trend to increase by week 2 (959 ± 154 N.s-1 vs 1139 ± 178 N.s-1, $P=0.111$) and significantly increased by week 4 (959 ± 154 N.s-1 vs 1222 ± 146 N.s-1, $P=0.007$). However, MVC showed no significant increase between 0 and 2 weeks (230 ± 20 vs 242 ± 18 , $P=0.160$) and only a trend to increase by week 4 (228 ± 24 vs 249 ± 17 , $P=0.052$). The present data suggest that 4 weeks of submaximal eccentric training are sufficient to increase both tendon stiffness and RTD and that these changes precede those of MVC. Therefore it is plausible to suggest that hypertrophy has a slower time course than tendon changes. An increase in tendon stiffness may be responsible for the increase in RTD, as a stiffer tendon would require less time for the tension to develop within the muscle. Taken collectively, these data demonstrate that adaptations in muscle and tendon may occur in a coordinated fashion, presumably to maintain the efficacy of the muscle-tendon unit. 1) Malliaras et al, 2013. THE RELATIONSHIP BETWEEN FUNCTIONAL MOVEMENT SCREEN SCORE AND THE PAST HISTORY OF INJURY IN HIGH SCHOOL WOMEN'S VOLLEYBALL PLAYERS

IDE, Y.1, OKAWA, M.2, HIRASAKI, K.1, NISHIYAMA, Y.2, FUJII, H.3

Kyusyu University of Nursing and Social Welfare

Introduction In order to prevent sports related injury is one of the essential roles as athletic trainers. Prior to the start of the each season, athletic trainers implement to physical evaluation to recognize their physical characteristics and abilities. Functional Movement Screen® (FMS) is one of the evaluation tools to identify the athletes' movement pattern, related to expected injuries (Cook, 2010). Therefore, the purpose of this study is to discover relationship between FMS score and the past history of injuries, to identify which region of injury has a great effect on FMS score. Method Forty-eight high school women volleyball players, without a current history of injuries, completed questionnaire which included the past history of injuries, frequency of injuries, and the period of injuries. FMS consists of seven fundamental movement patterns testing athletes' mobility, stability, and coordination. The data were analyzed by using SPSS statistical software. To determine the relationship between FMS score and history of injuries, we computed 2 stepwise multiple regressions. FMS scores were dichotomized using 14 as the cut point (Kiesel et al., 2007). Odds ratios were calculated using Mantel-Haenszel method with the corresponding 95% confidence intervals. Result The ankle was found the most frequently injured region, followed by fingers, the knee, the lower legs and the lower back. The average of FMS score was 11.42 ± 3.03 . The athletes who exposed the knee ($\beta = -.39$, $p = .002$), the shoulder ($\beta = -.33$, $p = .002$), and the ankle ($\beta = -.27$, $p = .027$) injuries more than three times had negative influence to FMS score. Where as, the athletes who have no histories of the lower back injuries had positive influence for FMS score (adjusted $R^2 = .36$). FMS score of the athletes who did not have histories of the lower back injuries ten times as high as that of the athletes who had histories of the lower back injuries (odds ratio = 10.26, CI95 = 1.2-87.5). Discussion Participation in high school athletics comes with risk for injury. To identify risk factors of sports related injury is significant important as athletic trainers. This study suggests without history of the lower back injury provides storing influence to improve FMS score. Having a history of the lower back injury appears to change movement patterns (McGill et al., 2012). Therefore, athletic trainers should provide core strength training such as static or dynamic to improve athletes' movement pattern. Reference Kiesel K, Plisky P, Voight M. (2007). IS THE DROP OF CUSHIONED RUNNING SHOE A KEY FEATURE FOR INJURY PREVENTION?

MALISOUX, L., CHAMBON, N., URHAUSEN, A., THEISEN, D.

Luxembourg Institute of Health

Introduction Until now, a clinical consensus as to whether or not the reduction of the drop of the shoes is protective against running-related injury (RRI) has not yet been reached. Several studies compared minimalist shoes with conventional shoes, but they provided conflicting results on the association with injury risk. Additionally, minimalist shoes are characterised by many specific features, thus preventing the identification of important shoe features for injury prevention. Therefore, the purpose of this randomised controlled trial was to determine if the drop of standard cushioned running shoes influences injury risk, and whether running regularity (>6 months of regular weekly practice over the last year) modifies the association between shoe drop and injury risk. Methods Leisure-time runners ($n=553$) were recruited for this randomised controlled trial and were required to report all information relative to their running activities, other sport practice, as well as any injury (time-loss definition, at least 1 day) on an internet based platform: www.tipps.lu. The participants received a pair of running shoes with a heel to toe drop of 10 mm (D10), 6 mm (D6) or 0 mm (D0). Apart from the shoe drop, the 3 versions were strictly identical. Cox regression analyses were used to compare RRI risk between the three groups based on hazard rate ratios (HR) and their 95% confidence intervals (95%CI), controlling for potential confounders. A stratified analysis was conducted to separately investigate the effect of shoe drop on RRI risk in occasional and regular runners. Results The participants recorded a total of 13160 hours of running, and 136 of them (25%) sustained at least one RRI during the 6-month follow-up. Most of the RRI affected tendons (53%) and the most often concerned anatomical locations were the lower leg (30%) and the knee (23%). The proportion of injured participants were 21.6%, 27.4% and 24.6% in the D10, D6 and D0 groups, respectively. The overall incidence was 10.3 RRI/1000h of running (95%CI=10.28; 10.39). The overall injury risk was not different amongst the participants who had received the D6 version (HR=1.30; 95%CI=0.86-1.98) or the D0 version (HR=1.17; 95%CI=0.76-1.80) when compared to the conventional D10 version. The stratified analysis revealed that low drop shoes (D6 and D0 grouped together) were associated with a lower RRI risk in occasional runners (HR=0.48; 95%CI=0.23-0.98), and with a higher injury risk in regular runners (HR=1.67; 95%CI=1.07-2.62). Discussion Overall, RRI risk was not influenced by the drop of standard cushioned running shoes. However, low drop shoes could be more hazardous for regular runners while they seem to be preferable for occasional runners to limit injury risk.

THE INFLUENCE OF SHOE CHARACTERISTICS ON INJURY IN DISTANCE RUNNERS

GOULET, G.C., AGRESTA, C.E., SOUTHERN, E.M., KESSLER, S.E., ZERNICKE, R.F., DENEWETH, J.M.

University of Michigan

Introduction Evidence-based recommendations on footwear for injury prevention are scarce. There is limited evidence that suggests transitioning from traditional to minimalist shoes increases the incidence of injury, particularly of the foot and leg (Ryan et al.). However, no evidence exists for the effects of different cushioning levels or heel-to-toe drop. The aim of our study was to assess incidence of injury in distance runners after a 4-week training period in zero-drop running shoes with varying levels of cushioning. Methods Thirty experienced runners (15 males; 15 females) were enrolled. Data from three participants were excluded from analyses due to incomplete participation. Subjects ran at 70% VO_{2max} speed for 10 minutes in their habitual shoe (HAB), a minimal shoe (MIN; New Balance Minimus), and a maximal shoe (MAX; Altra Paradigm), which were selected for their zero-drop, similar fit, and disparate midsole thickness (11 and 25 mm). Runners were randomly assigned MIN or MAX to wear for all runs for four weeks. Details of all runs, including mileage, time, intensity, surface, and musculoskeletal complaints were monitored using electronic training logs. Data were analyzed using multiple

linear regression analysis. Results Approximately 26% of the runners became injured and had to either stop running completely or significantly alter their running mileage, duration, and/or speed during the 4-week period (i.e., major complaint). Another 37% reported minor musculoskeletal complaints during some of their runs. All injuries and complaints were of the foot or leg. Shoe type was significantly associated with injury with all injuries occurring in the MIN group ($p=0.005$). Difference in heel height from HAB to novel shoe demonstrated a trend ($p=0.10$), while heel-to-toe drop difference from HAB to novel shoe was not significantly associated with injury ($p=0.51$). The difference in shoe weight from HAB to novel shoe increased as injury severity increased. Runners who reported no pain had a 38.6 g change, those with minor complaints had a 45.9 g change, those with major complaints had a 78.7 g change, and those who had to stop running completely had a 92.3 g reduction in shoe weight. Discussion All injuries occurred in the MIN group with half of the runners in this group becoming injured over four weeks. Individual characteristics such as age, gender, running experience, typical weekly mileage, or mileage during evaluation period did not add significantly to the explanation of injury. Since both MIN and MAX shoes had a zero heel-to-toe drop, it appears that other factors influence injury risk when transitioning to a new shoe. Additional research is needed to determine what is unique about runners in the MIN group who were able to adapt successfully to the novel shoe. References Ryan M., et al. IMMEDIATE EFFECTS OF ELASTIC KNEE BRACES ON FRONTAL PLANE MOTION BIOMECHANICS IN HEALTHY MEN

LI, J.Y., GUO, L.Y.

Kaohsiung Medical University

Introduction Knee joint damage, is commonly occurred in soccer players, especially the fraction of anterior cruciate ligament, medial collateral ligament and medial meniscus (Cowley, Ford, Myer, Kerozek, & Hewett, 2006). Moreover, players often return the court without recovery of injuries. Chronic knee joint injury may progressively lead to osteoarthritis (OA). Current treatment includes medical therapy, surgery and exercise; besides, wearing knee joint braces, wedged insoles and elastic knee sleeves are alternative ways for relieving symptoms and delaying the disease progression (Schween et al., 2015). Previous study (Ota et al., 2015) has demonstrated that decreasing knee adduction moment is considerable important on preventing OA. The purpose of this study is to examine immediate effects of elastic knee braces on frontal plane motion biomechanics. Methods A crossover study was carried by 15 healthy men. The participants were requested to wear either nothing (control), elastic brace 1 (EB1; with metal sticks supported) and elastic brace 2 (EB2; with plastic sticks supported) in a random manner. Afterwards, they performed three movements (i.e. straight walking, straight running and cutting) commonly seen in soccer players. 3D motion analysis system and force plates were used to measure the kinematic and kinetic parameters of the knee frontal plane. One-way ANOVA with Tukey's post hoc was applied to compare all parameters between treatments. Results In EB1 treatment, the results showed the knee abduction angle in cutting was significantly less than control ($P < 0.05$); however, it did not differ in walking and running. In EB2 treatment, there were no differences in the knee abduction angle in three movements compared to control. In addition, no differences were found in knee abduction moment in three movements between each treatment. Discussion Previous study (Schween et al., 2015) investigated the effect of wearing elastic braces on knee adduction when performing 10-m straight walk in OA patients. In our study, we first confirmed the impact on the additional two movements (i.e. running and cutting). EB1 provided better protective benefits on the cutting, the movement needed more stability due to turning right angles. The materials of elastic braces played an extremely important role on remaining stability. Our study demonstrated that the EB1, with metal sticks supported, exerted better stiffness. In conclusion, our data provided the novel evidences of elastic brace on decreasing knee abduction angle when performing cutting. References Cowley, H. R., Ford, K. R., Myer, G. D., Kerozek, T. WAVELET ANALYSIS OF ISOKINETIC KNEE EXTENSION TORQUE CHARACTERISTICS OF VOLLEYBALL PLAYERS DURING THE ANNUAL MACROCYCLE

CZAPLICKI, A., KUNISZYK-JOZKOWIAK, W., SLIWA, M.

Academy of Physical Education

Introduction Isokinetic extension and flexion peak torques are frequently used to assess strength possibilities of volleyball players in different periods of an annual macrocycle (Hadzic et al., 2010; Rousanoglu et al., 2013). Much less attention has, however, been paid to quantify irregularities on isokinetic torques time-curves occurring during the competitive season. The aim of this work is thus to inspect such undulations using a discrete wavelet transform methodology. It was hypothesised that a time-frequency analysis was suitable to quantify the changes in the knee extension torque characteristics throughout the annual macrocycle. Methods The research was conducted among 13 volleyball players from a second-division team. The torque of knee extensors was measured using Biodek System Pro4. The measurements were done at the end of four different periods of the annual macrocycle: the transition period, the preparatory period, as well as the first and the second rounds of the competition. A Daubechies 4 wavelet was chosen for a time-frequency analysis of the signal originating from the dynamometer. ANOVA with repeated measures was applied to check the differences among the research variables. Results The wavelet decomposition revealed significant differences in high frequency energy content between the first and fourth ($p \leq 0.0087$), the second and fourth ($p \leq 0.0097$) and between the third and the fourth ($p \leq 0.021$) measurements. There were no statistically significant differences between the first three measurements. Discussion The high frequency energy contained within the details of the decomposed signal detected after the second round of the competition may reflect indirectly a fatigue of the knee extensors. The changes in energy spectrum have been already observed in biomechanics Tsepis et al. (2004) who reported the higher-frequency content in the isokinetic time-torque characteristics of ACL deficient knees compared to the intact ones. The obtained results may be of practical value, since they can help to assess the players' muscle fatigue during the macrocycle, verify and modify the training methods which are being used, and adopt an individual approach to each player. IS FEAR OF INJURY ASSOCIATED WITH BREAKFALL KINEMATICS FOR OSOTO-GARI IN NOVICE JUDOKAS?

SENTARO, K.1, ISHII, T.1, MATSUDA, T.2, HASHIMOTO, T.1

Ryotokuji University1: RYOTOKUJI UNIVERSITY (Urayasu, Japan), 2: UEKUSAGAKUEN UNIVERSITY (Chiba, Japan)

Introduction It has been reported that direct head contact to mat by being thrown backward with osoto-gari is the leading cause of judo-related head injury, including catastrophic injuries, such as acute subdural hematoma (Kamitani et al, 2013). Judo experts have agreed that breakfall for osoto-gari is a physically and mentally demanding skill, explaining the higher risk of injuries in novice judokas. The perception of risk and incidence of injury may lead to a judoka's fear of injury, which could even be more detrimental to breakfall kinematics. However, studies on the association of perceived fear with breakfall kinematics are limited; therefore, we aimed to study this association in novice judokas. **Methods** We recruited 10 novice judokas who had not previously participated in judo competitions but had attended a minimum of 10 sessions of a judo course offered by Ryotokuji university. The test protocol included three sets of breakfall in response to being thrown with osoto-gari onto the mat. Subsequently, all participants were asked by one assessor to gauge their fear of injury and were evaluated using a 5-rank Likert scale. Four participants who answered 'felt fear in the breakfall motion' were assigned to the fear group (F group), whereas four participants who answered 'not much fear felt' were assigned to the no fear group (NF group). Two participants who answered 'neither' were eliminated from further analysis. We obtained three-dimensional marker trajectory data of the 41 attached markers using an 18-camera Mac3D motion analysis system (Motion Analysis, Inc. CA, USA). (500 Hz) and calculated neck, trunk, right/left hip and right/left knee joint angles in the sagittal (z-x) plane as well as the peak neck extension momentum during the breakfall motion. **Results** There were no remarkable differences in neck, trunk, hip and knee angle pattern during the breakfall motion for osoto-gari between the F and NF groups; the groups showed similar characteristics as reported previously (Koshida et al, 2014). In addition, we found little difference in peak neck extension momentum between the groups [F group: 1.04 (0.77–1.22) kg m²/s⁻¹; NF group: 1.01 (0.70–1.18) kg m²/s⁻¹]. **Discussion** The results indicate that the fear of injury may not be associated with breakfall kinematics and possible risk of injury associated with being thrown with osoto-gari in novice judokas; this suggests that a coach should probably not rely only on the learner's feeling of fear when making progress on the breakfall learning process. Considering the severity of head injury that occurs by being thrown with osoto-gari in novice judokas, it is necessary that coaches develop appropriate skills to evaluate breakfall motion for osoto-gari. **References** Kamitani T, Nimura Y, Nagahiro S, Miyazaki S, Tomatsu, T. EPIDEMIOLOGY OF BACK PAIN IN GERMAN ELITE ATHLETES

TROMPETER, K., FETT, D., PLATEN, P.

Ruhr-University Bochum

Introduction The importance of physical activity in the treatment of back pain (BP) is generally accepted. However, an increase in physical activity has been suggested to be both a preventive factor and a possible risk factor for BP. It is well known that sports participation generally influences our health in a positive way, but there is a lack of knowledge about the optimal dose-effect relation. There is evidence for an association between high physical workloads and back injury. In sports, BP is commonly reported to be a frequent disorder but it is still unclear if its prevalence is higher than in nonathletes. The aim of this investigation was to determine lifetime prevalence (LT), 12-months prevalence (12m-P) and point prevalence (PP) of BP in German elite athletes regarding the pain intensity and the exact localization at the spine. **Methods** The study was designed as a cross-sectional survey among athletes competing at the national elite level in different sports. An online-based questionnaire was sent to N≈4000 athletes from different sports disciplines by the German Olympic Sports Confederation. The questionnaire consisted of several validated questionnaires on BP (Nordic questionnaire [1], questionnaire for grading the severity of chronic pain [2]). Additionally a self-developed questionnaire focusing different aspects of training and competition was used to evaluate the athletic workloads. **Results** A sample of N=1094 German elite athletes (583 females, 508 males, 20.7±5.0 years, 176.6±10.5 cm, 70.6±14.1 kg, training volume: 18.3±7.9 hours/week) took part in the survey (response rate≈25%). LT of BP was 88.7%, 12m-P was 81.4% and PP was 49.2%. The most often occurred localization was the lower back with a LT of 77.6%, 12m-P of 65.5% and PP of 33.8%. Regarding the sports disciplines individually LT of BP and low back pain ranges 57.9–100% and 42.1–92.9%, respectively. Very high prevalence rates of 94.7–100% were found in canoeing, dancing, rowing and water-polo. **Discussion** The results of this investigation indicate that BP is a present problem in German elite athletes. Especially sports disciplines with high mechanical loads on the spine seem to be affected. High training volume up to 45 hours per week might be responsible for high prevalence rates. The results of this investigation underline the necessity of BP prevention in German elite athletes. **Acknowledgement:** The study was supported by the Federal Institute for Sport Science, Germany (ZMVII-080102A/11-18). **References:** [1] Kourinka I. et al. PRECONDITIONING WITH ISCHEMIC EXERCISE PRESERVES QUADRICEPS FEMORIS MUSCLE ENDURANCE PERFORMANCE FOLLOWING ACL RECONSTRUCTION

KACIN, A.1, GRAPAR ZARGI, T.1, STRAZAR, K.2, DROBNIC, M.2

1: UL ZF Ljubljana, Slovenia, 2: UKC-LJ DOS Ljubljana, Slovenia

Introduction Quadriceps f. (QF) muscle weakness is recognised as a key factor of poor knee function, despite optimal reconstruction of ACL. Limb surgery performed with tourniquet induces mechanical compression and augments ischemic stress, which can further accelerate QF muscle weakness (Appell et al, 2004) Preconditioning of skeletal muscle with periods of intermittent ischemic exposures has been shown to have positive effects on cell survival (Murphy et al, 2010). In addition, muscle ischemia in combination with low-load exercise was proven to be superior from free blood flow exercise in terms of enhancing vascular function (Patterson & Ferguson, 2010), oxygen delivery and muscle endurance (Kacin & Strazar, 2011). Present study thus assessed effects of short-term preconditioning with ischemic exercise can preserve QF endurance within the first 12 wks after ACL reconstruction. **Methods** Twenty subjects, undergoing ACL reconstruction with ipsilateral hamstrings autographs, performed 5 exercise sessions during the last 10 days before surgery. They were quasi-randomly assigned into two groups: ISCHEMIC group - performing low-load blood flow restricted (ischemic) knee-extension exercise or SHAM group – replicating the same exercise volume with free blood flow. Tissue hemoglobin kinetics (NIRS) and surface EMG were measured on QF muscle during isometric contraction performed at 30% MVIC torque to volitional failure prior to preconditioning and at 4 and 12 weeks post-surgery. **Results** Time of sustained QF contraction decreased ($p=0.002$) in SHAM group by 100 ± 91 s at 4 wks and returned to preoperative values at 12 wks. No decline in contraction time was observed in ISCHEMIC group at 4 wks, whereas an in-

crease of 54 ± 50 s was observed at 12 wks post-surgery. A $33 \pm 8\%$ increase ($p=0.018$) in RMS EMG amplitude, with concomitant $56 \pm 16\%$ increase ($p=0.010$) in muscle blood flow, was observed only in ISCHEMIC group at 4 wks after surgery. Discussion This is the first study to demonstrate a positive effect of short-term ischemic exercise on QF muscle endurance in patients after arthroscopic ACL reconstruction. Enhanced endurance of QF muscle was brought about by augmented muscle fibre recruitment for the given torque output. This most likely resulted from combination of preserved muscle activation capacity and enhanced regulation of oxygen delivery to the muscle. The latter may be an evidence of persisting effect of ischemic preconditioning on density and function of muscle microcirculation within first 4 wks after surgery with prolonged tourniquet application. A LONGITUDINAL ANALYSIS OF RENAL FUNCTION IN TRANSPLANTED CYCLISTS

TOTTI, V., ROI, G.S., MOSCONI, G., DI MICHELE, R., MERNI, F., NANNI COSTA, A.

University of Bologna

INTRODUCTION It's well known that solid organ transplant recipients may return to sport practice after transplantation. However, no study has still evaluated the effects of competing in a cycling marathon (CM) on renal function change across years in transplanted cyclists (TC). The purpose of this case series was to analyse the renal function in TC having participated to three consecutive editions of an annual 130-km road MC. METHOD The renal function of 5 males TC (age: 52 ± 11 yrs; BMI: 24.7 ± 3.1 kg/m 2), who underwent transplant (1 heart, 2 liver, 2 kidney) 7.6 ± 6.4 yrs before the first examined MC, were evaluated through venous blood and urine specimens: basal, measured the day before the race (Pre), immediately after the race finish (Post), and 24 hours after the race finish (24h). RESULTS All participants aimed to successfully complete all CMs, with everyone's individual final time being approximately the same in the three editions. No meaningful change was observed regarding basal values of examined blood and urine indices during the study period in any subject. For any cyclist, there were no relevant changes across years of Pre/Post, Pre/24h, and Post/24h differences for Hb, haematocrit, urea, and urine specific gravity. Similarly, Pre/Post changes observed for eGFR, creatinine and proteinuria (on average -7%, +26%, and +58%, respectively) were almost the same in the three CM editions. Also, in all CT and for all CM editions, these variables showed values returning to baseline at 24h. DISCUSSION The present findings are in agreement with a previous study (Neumayr et al., 2003), reporting that, in healthy subjects, renal functional parameters significantly increase immediately after a cycling race, but return to baseline values after 24 hours. This demonstrates that a temporary "impairment of renal function" may be a physiological response to the CM. An increased proteinuria was observed immediately after intense physical efforts (Bellingeri et al., 2008), likely related to the high muscular work required by the effort. The present results show, also for proteinuria, that the response to a prolonged physical effort in TC involves physiological changes similar to those exhibited by healthy subjects. Furthermore, in well trained TC, the ability to recover after a CM seems to be maintained across years.

INFLUENCE OF TEAM COHESION AND MOTIVATIONAL CLIMATE ON SATISFACTION WITH TEAM PERFORMANCE AT A LACROSSE WORLD CUP

OHLERT, J., MCCOURT, M.

German Sport University Cologne

Introduction Several studies show that the team cohesion as well as the coach created motivational climate in a team have an influence on other important team variables like satisfaction with the team or team performance. In general, high values of the four factors of group cohesion as well as a mastery climate are linked to positive outcomes, whereas an ego climate is associated with more negative outcomes. The aim of our study was to examine the influence of team cohesion and motivational climate on satisfaction with performance during the women's Lacrosse World Cup. Method In total, 127 players from nine different teams (of 19 participating teams) took part in the survey. The mean age was 26.0 years ($SD = 4.6$) with an average of 3.4 years ($SD = 3.2$) with their current team. Players answered questions regarding team cohesion (KIT-L2; Ohlert, Kleinknecht & Kleinert, 2015) and coach created motivational climate (PMCSQ-2; Newton, Duda & Yin, 2000) prior to the first World Cup game. After completion of the last game they were asked questions regarding their satisfaction with team performance (STP) and personal performance (SPP) throughout the World Cup. Canonical correlations were performed to analyse the interactions between both group cohesion and the two satisfaction variables as well as motivational climate and satisfaction. Results The canonical correlation between cohesion and satisfaction (.42) indicates that all four factors of cohesion are associated with both STP and SPP, as all factors correlated with the canonical variate (.55 to .89). However, for motivational climate (.38 in total), only a mastery climate was associated with STP and SPP (.99), as ego orientation only correlated at .15 with the respective canonical variate. Discussion Our results indicate that higher group cohesion predicts both to higher STP and SPP throughout a World Cup tournament. For motivational climate, it is important to notice that a coach induced ego climate had no effect on satisfaction with performance (personal and team), whereas a mastery climate shows the expected effect. A possible explanation might be that a high competitive environment of a World Cup tournament comes with high ego climate within a team anyway. Thus, focus of coaches should be on a mastery climate, especially within a highly competitive situation. References Newton, M. L., Duda, J. L., Yin, Z. (2000). J Sports Sci, 18, 275-290. SHARED MENTAL MODELS IN HANDBALL AND SOCCER ELITE TEAMS.

GISKE, R., GJERDE, J., GARD, H.S., JOHANSEN, B.T.

University of Stavanger

Shared mental model (SMM) is held as important facilitating team performance and it is considered a useful construct for analysing elite team practice. Cannon-Bowers, Salas, & Converse (1993) describe SMM as knowledge structures held by members of a team that enable them to form accurate explanations and expectations for the task, and in turn, to coordinate their actions and adapt their behaviour to demands of the task and other team members. Giske, Rodahl & Høigaard (2015) argues that SMM is a useful construct for analysing elite team practice and coaching behaviour. The aim of this study is to explore how elite coaches in handball and soccer reflect on team cognitive properties and how these attributes are developed through team practice. In study 1 we investigated the reflections on shared mental models and coaching efforts to develop it in National handball teams. Three coaches participated. In study 2 we elaborate coaches' reflections and players' experience of how shared notions of game tasks is affected by practice in two elite soccer teams. Two UFFA-pro coaches from Norwegian Premier League, and four elite players volunteered to participate. A qualitative content analysis (Morgan, 1993) of the verbatim transcription was undertaken. The interviews in both studies revealed that measurements such as use of video, team meetings, and field practice were used in both ballgames to enhance a shared mental model. The national coaches in handball reported systematic practice with intention to promote coordination where repetitions of the coordinative patterns in typical game situation were emphasized. Distribution of tasks in game situations and timing seems to be vital pedagogical content elements contributing to establish shared situational awareness. Implicit communication is a characteristic of teams sharing a mental model and this seems to be especially prominent in handball coaches' reflections and proactive distinct bodily movements are emphasised as a crucial requirement for coordination. The soccer players' draws attention towards knowledge about team member attributes within more explicit task team generic guidelines. References Cannon-Bowers, J. A., Salas, E., & Converse, S. A. (1993). Shared mental models in expert team decision-making. In N. J. Castellan (Ed.), Individual and group decision making: Current issues (pp. 221-246). Hillsdale, NJ: Erlbaum. A CORRELATIONAL ANALYSIS OF PERFORMANCE STRATEGIES AND MOOD STATES IN TWO UNIVERSITY BASKETBALL TEAMS

SOOS, I.I, MARTINEZ, J.C.F.2, HAMAR, P.3, WHYTE, I.I, SZABO, A.4

1University of Sunderland, UK, 2University of Almeria, 3Hungarian University of Physical Education, Budapest, 4Eotvos Lorand University, Budapest

Introduction Performance strategies play an important role in sport success from college (Dachen, 2012) to Olympic levels (Taylor, Gould & Rolo, 2008). One of the key strategies is to learn how to control emotions and develop optimal emotional states in training and competition. The aim of this research was to investigate the relationship between performance strategies and mood states in a British University and College Sport (BUCS) first and second division basketball teams in training and competition situations. Methods Fourteen male university students (mean age=22.9 years) volunteered for the study. They were from a BUCS league's first (n=7) and second (n=7) division teams in the North East of England. Players completed the Test of Performance Strategies scale and the Brunel Mood Scale prior to training and match conditions. Data were analysed by performing descriptive statistics, Pearson's correlation, and independent and paired-samples T-tests using IBM SPSS (v22) software package. Results All players reported higher vigor ($p=.02$) and used more self-talk ($p=.03$) in training than in competition. Players in the first team exhibited higher levels of automaticity than players in the second team ($p=.004$). In training, a positive correlation was found between attentional control and emotional control ($r=.57$, $p<.05$) as well as between goal setting and tension ($r=.56$, $p<.05$). During the matches automaticity was positively associated with relaxation ($r=.61$, $p<.05$) and negatively with tension ($r=-.79$, $p<.01$), while activation was inversely related to both negative thinking ($r=-.58$, $p<.05$) and depression ($r=-.54$, $p<.05$). Discussion and Conclusions The findings show that higher level performers in the first team use more automated technical and tactical skills than lower level players in the second team, which is in accord with current knowledge (Taylor et al., 2008). Further, the here investigated teams (placed at the bottom in their own league) appeared to be intimidated to use self-talk during matches, when vigor also dropped. The correlations are based on a low sample size and, therefore, with larger samples they would be even more powerful. Nevertheless, they show that activation and automaticity are linked to positive mood states during matches. Another positive link between emotional and attentional control suggests that stable emotions may be paired with better concentration. The positive link between goal setting and tension could reflect an inner struggle to achieve the set goals. References Dachen, I. (2012). Int. J. Beh. Soc. Mov. Sci., 1 (14), 139-147. VISUAL SEARCH BEHAVIOUR IN SOCCER: WHICH PREDICTOR COULD EXPLAIN COMPETITIVE LEVEL?

BAGATIN, R.T., PADILHA, M.B., RIBEIRO, J., AQUINO, R., RAGO, V., OLIVEIRA, J., GARGANTA, J. CASANOVA, F.

University of Porto

Introduction As one of the perceptual-cognitive skill, the visual search behaviour allows soccer players to seek relevant information that helps them in deciding the accurate actions to execute during a match. In this sense, the aim of this study was to identify which predictors of visual search behaviour during a prolonged intermittent exercise protocol could explain competitive level. Methods Sixteen soccer players were separated in two groups of eight players each, according to Elite (mean age = 24.6 yr, SD=3.9 yr; Semi and professional level 5.1 yr, SD =2.4 yr) and Non-elite (mean age = 26.3 yr, SD=2.9 yr; amateur level = 2.1 yr, SD=2.4 yr). The Applied Science Laboratories (ASL) 3000 eye-movement registration system was used by participants during the whole protocol test. To simulate the physiological demands of a soccer game, an intermittent exercise protocol was used (Drust, Reilly, & Cable, 2000). The protocol was consisted in 119 minutes divided in first half (52 minutes), recovery phase (15 minutes) and second half (52 minutes). Data were collected in four moments of test sessions (1^o and 2^o in first half time, 3^o and 4^o in second half). The measures from visual search behaviour comprised the Number of fixation per locations (NFL) (ball, teammate, opposition, player in possession of the ball, and undefined), and mean fixation duration per trial. The undefined category was excluded (less than 1%). The inter-observer agreement value was 99% (were reanalysed 25% of the data). In order to explain the variance of the dependent variable logistical regression were performed, as well as the correlation coefficient of determination and Beta value (β). The alpha significant value was set at .05. Results The logistic regression model was statistically significant, χ^2 (1)=7.31 ($p=0.007$). The model effect size was 0.36 and correctly classified 50.0% of cases. The increasing tendency of

fixation durations values on the player in possession of the ball could explain the expertise level (i.e. elite or not-elite) of soccer players ($OR=0.99$; $p=0.04$). Discussion The results showed that the fixation durations on the player in possession of the ball could explain the competitive level when verified this variable in the 2^o half time (3^o moment). Thus, elite players demonstrated superior fixation duration on the player in possession of the ball. In this way, our results suggested that the superior performance of elite players was associated with the selectivity of the perceptual resources, also suggested by others researchers (Martins et al., 2014). SUPPORTING ATHLETE CAREERS AND DEVELOPMENT – CHANGING APPROACHES FOR A CHANGING WORLD

SAUNDERS, J., PINK, M.

Australian Catholic University

Introduction Athlete career support has developed over a quarter of a century in Australia and has followed a similar pattern to European models. The Life Skills for Elite Athletes Program (LEAP) was launched in 1991 motivated by the lack of opportunity for athletes seeking a career at the conclusion of their sporting careers. This was followed by an expanded Athlete Career and Education Program. It was possible to identify two discrete threads in these programs. A basic thrust on facilitating a healthy transition from athletic retirement, influenced by findings from literature on athlete development that many athletes over-invested in their identity as athletes, thus foreclosing on other aspects of personal development and identity. Review Our review shows that in Australia as in Europe much attention was focused on facilitating athletes' ability to continue in academic study and prepare for an alternative career to move into on completion of their sporting careers. However data from our own research (Saunders & Pink, 2004) are used to support our belief that the nature of Athletes' work has changed and a different response is now needed by those who work in athlete development to provide more effective support. Findings We argue that recent changes in the demands of the professional sport have led to increased time and commitment required for the development and maintenance of the sports career (Pink, Saunders, & Stynes, 2015). This has led to diminished relevance of the concepts of dual and/or alternative careers. Paradoxically we provide evidence that there has been increasing length in the careers experienced in many sports alongside increasing opportunities for 'switching' into jobs within the sport and related industrial sectors. Conclusion Current approaches such as the AIS Personal Excellence program have focused on the notion of holistic personal development or, as expressed by the Max360 initiative of the AFLPA, "changing the 'preparing for life after football' narrative, to 'assisting players to maximise the opportunities that an AFL career provides'." This is consistent with strategies adopted to avoid burnout in early careers outside of sport (Schaufeli, Leiter & Maslach, 2009). Future research should seek to identify means for such approaches to be fully supported by athletes' sporting organisations and how their cultures can more accurately meet the needs of the athletes heavily immersed in their athletic career References Pink, M., Saunders, J. & Stynes, J. WHEN GIRLS ARE MORE EMPATHIC AND NORM-ENFORCING THAN BOYS ON THE FOOTBALL FIELD?

VAN LANGE, P.A.M.

Vrije Universiteit Amsterdam

Introduction A key revolution in the past three decades is the enormous growth in women's football. This raises intriguing questions that include and go beyond the evolution of sex differences. How are women and men different, when they are playing soccer? Being more empathic in general, might we, for example, see young female football players exhibit greater empathy on the field? If so, how? And when do girls and boys differ corrective behaviors by showing disapproval of one another's fouls? Such knowledge should ultimately help us generate new solutions to enduring problems in soccer, such as violence in and around the field. Methods In total, 107 children (55 boys, 52 girls, age 10-18) participated in a web-based experiment. They were asked to imagine themselves at the soccer field being in control of the ball when another player falls on the ground. Using a within-participants design, we manipulated location (distant or close to the other team's goal) and team of fallen player (own or other team). We assessed the extent to which participants thought they would quickly stop to look how the fallen player was doing, which served as our measure of empathy. Also, we examined the likelihood of girls and boys "openly disapproving" of a foul enacted by a player of their own versus the other team. Results All participants exhibited greater empathy when the other player fell on a location farther away from the other team's goal, and when the player was from the own team. Most interestingly, boys and girls differed in one key aspect: At midfield, boys and girls were about equally empathic, but closer to the goal of the other team (when scoring is a clear possibility) boys were far less empathic than girls. Disapproval of fouls also uncovered intriguing differences. Reportedly, while girls were about equally likely to show disapproval when against player of their own versus the other team, boys were far more likely to do so when the foul was conducted by a player from the other (versus own) team. Discussion When do sex differences in football become manifest? We find that when scoring becomes a real possibility (when the distance to the goal is small), girls still enact empathy while boys move on to continue playing. This finding is consistent with the notion that men more than women are oriented on pursuing a single goal rather than multiple goals. We also find differences in showing fault disapproval. While boys are clearly biased in favor of their own team, girls are about equally "corrective" towards players of their own and the other team. The latter finding is important, because it is possible that showing disapproval of especially unnecessary fouls (e.g., at the midfield) by own team players may often help the team to win – and to win by proper means. EVALUATION OF PSYCHOLOGICAL SKILLS IN FEMALE SOCCER PLAYERS OF DIFFERENT CATEGORY LEVELS. A LONGITUDINAL STUDY DURING ONE-YEAR LEAGUE COMPETITION

GIL-NOGUÉS, J.1, FERNÁNDEZ-CAMPOS, F.J.2, DE BERNARDO, N.2,3, BARRIOS, C.2

1: School of Doctorate, UCV (Valencia, Spain), 2: Institute for Research on Musculoskeletal Disorders, UCV (Valencia, Spain), 3: School of Physiotherapy, UCV (Valencia, Spain)

Introduction Several studies have already dealt with the physiologic demands of soccer; however, little attention has been paid to the influence of psychological aspects, particularly in female participants. The purposes of this study were: 1) to describe the profile of psycho-

logical skills in different Spanish players of female soccer; 2) to examine the influence of age and the level of practice on these skills. Methods A sample of 101 female soccer players completed a validated Spanish version of the Athletic Coping Skills Inventory (ACSI-28) (Graupera et al., 2011) in the National League from 2013 to 2014. The stratification of the sample included 20 players belonging to the first national division, 33 competing in the second national division, and 48 from inferior categories. The ACSI-28 questionnaire (Smith et al., 1995) examines perceptions in the practice and competition of the athletes: coping with adversity, peaking under pressure, goal setting/mental preparation, concentration, freedom from worry, confidence and coachability. The test was administrated in three stages: at the beginning, at middle stage, and at the end of the tournament. Psychological profile were compared in relation to the division (Wilcoxon test). Correlations between factors from ACSI-28 (Spearman Rho) at the beginning and at the end of the season were also analyzed. Results The analysis of the questionnaires showed differences between the national and the other categories of players. At the end of the season the players of lower categories had better scores than the first and second national divisions in two factors: coping with adversity ($p<0.05$) and coachability ($p<0.01$). Likewise, these players improve their ability in coping with adversity ($p<0.05$). The players of first division significantly decreased their coachability ($p<0.05$). The results of the factors analyzed were independent of the level of education of the players. There were significant differences between playing positions and results of capacity concentration (lower in goalkeepers, $p<0.05$) and general coping resources (lower in forwards, $p<0.05$). Discussion The first division players were better prepared to deal with psychological distress involving soccer competition and reported better emotional self-control. The use of the ACSI-28 allows a friendly approach to the specific psychological skills required in soccer. A better understanding of the psychological factors underlying female soccer at different categories might allow for the development of interventions to improve psychological skills of participants.

THE ROLE OF SIDE ENTRÉES IN GERMAN AGE-GROUP SWIMMING

STAUB, I., BRIXIUS, K., BIEDER, A.

German Sport University Cologne

INTRODUCTION Every nation aims to send successful athletes to international top events. For this reason national swimming associations provide multi-year training plans to operate long term development for identified young talents. To quantify the role of side-entrees (newcomers at progressed developmental level, ♂ > age 15, ♀ > age 14) into German Age Group Swimming a longitudinal investigation of careers was made. METHODS To examine the rate of lateral entrees into German competitive swimming the 100 best age-group swimming performances (long course) of eight subsequent years (2004-2013) were analyzed. Here the focus was on the age-groups 1993 - 1995 (♂ n = 1.862; ♀ n = 1.993). The athletes were assigned to one of the following groups: Survivors (athletes who remained in the rankings in all previous years), Returnees (athletes who had at least one year without ranking and made it back into the top 100) and Newcomers (athletes who got ranked for the first time). RESULTS The Newcomer rate for male swimmers decreased within the ages of 12-14 years in boys (23,1%; 16,7%; 12,3%), stabilizes over the ages 15-17 (10,97% ± 0,12%) and increases again at the age of 18 (14,5%). For girls the rate decreases as well from 12-14 years (20%; 14,3%; 12,3%), stabilizes at age 15/16 (14,0% ± 0,7%) and increases earlier than the rate of boys at the age of 17 (15,4%) until 18 (21,3%). DISCUSSION We conclude that there are only a few continuous carriers among German age-group-swimmers. The role of side-entrees increases with progression of development. The rates decrease in the same age-groups of male and female swimmers but increase one year earlier for the girls. Future research should analyse the qualitative role of these Newcomers. BALL PLACEMENT IN A TENNIS MATCH OF WORLD-CLASS PLAYERS AS A CASE STUDY

KIM, H., ZELAZNIK, H.N.

Purdue University

Introduction In a tennis match, the basic idea is that the players endeavor to score winning points as well as to prevent their opponent from scoring points. The outcome of their effort is embedded in tennis ball placement. If one player strikes the ball to the opposite side of his opponent, then the receiver has to change his behavior to return the ball on the court. This unique behavior in tennis can be described by analyzing ball placement, and ball placement data also can be a performance indicator in a tennis match. Methods The 1st round match of men's singles in the 2013 Australian Open was selected for analysis. The match was converted to jpg files for every frame. The frames contain the ball placement on the court and a custom-made Matlab program caught the ball placement. The center of the court was the origin point as (0,0). The x-axis and y-axis corresponded to the horizontal and vertical placement of the tennis court, respectively. The Matlab program reconstructed the ball placement by transforming the ball placement from the captured frames to real-world locations. We obtained a time-series of ball placement for each player. The time-series of ball placement for the horizontal data and for the vertical data were classified with respect to each player. Detrended Fluctuation Analysis (DFA) was applied to every set of time-series data to determine the statistical self-affinity. Results There were overall 634 frames of ball placement for each player. After the serves and outs were excluded, the valid ball placements for player 1 was 170 and for player 2 was 152. It was found that the horizontal ball placement showed a u-shape frequency histogram, which meant both players tended to send the ball mostly to the left and right. This shape corresponded to the basic idea of tennis strategy to force the opponent to cover more area on the court. There was a 36.6 cm difference in the average radial distance of ball placement from the center of the court. However, DFA results for both players were almost the same with the alpha value of 0.53 and 0.54. In horizontal ball placement, an 18.65 cm difference was shown and the alpha value was 0.53 for player 1 and 0.65 for player 2. The alpha value was 0.51 and 0.56 respectively, which showed a 38.36 cm difference in vertical ball placement. Discussion This study showed that professional tennis players seem to produce uncorrelated shots. DFA results were approximately 0.5, a criterion known as white noise. It is likely that the results are due to the high ability of each player. An exception was found for player 2 in horizontal ball placement possibly due to ranking differences. Future comparative research is necessary to analyze less skilled players. References Lames M. (2006). J Sports Med, 5, 556-560. Palut Y., Zanone P-G. (2005). J Sports Sci, 23(10), 1021-1032. BEING TOP LEVEL YOUTH IS NEITHER SUFFICIENT NOR NECESSARY TO BECOME A TOP LEVEL ATHLETE.

BOCCIA, G.1,2, MOISÈ, P.3, FRANCESCHI, A.3, TROVA, F.3, PANERO, D.3, LA TORRE, A.4, RAINOLDI, A.2, SCHENA, F.1,5, CARDINALE, M.6

1 CeRISM (Rovereto, Italy); 2 Motor Science Research Center (Torino, Italy); 3 SUISM (Torino, Italy); 4 Department of Biomedical Sciences for Health; 5 Department of Neurological, Neuropsychological,

Introduction. The idea that early sport success, because of early sport specialization or early physical maturation, can be detrimental for long-term sport performance is still under debate (Moesch et al. 2011, Tønnessen et al. 2015). Limited information is available on many sports on the pathway to elite performance. The aims of this study were to investigate if the age of starting competition, the youth annual rate of change in performance, and the age of reaching personal best performance influenced reaching international level performances of high and long jumpers. We also wanted to investigate how many top level youth athletes became top level athletes and how many top level athletes were considered top level when performing in youth categories. Methods. The long and high jump rankings of the Italian Track and Field Federation were collected for each age category, i.e. from the age of 12 to career termination, and both genders from the year 1994 to 2014. The individuals of each discipline were ranked on the base of the z-score of their personal best performance. The annual rate of change in jumping performance, the age of beginning competitions, and the age when they reached their best performance were identified for each individual. Top athletes were identified as those with a z-score between 97 and 100. Results. The initial age of entering competitions of top level athlete was not different with respect to the rest of sample. Whereas the age at which the personal best performance was obtained was higher in top level athletes than in the rest of the sample. Top level athletes showed an overall higher rate of change in performance from the age of 14 to the age of 18 years when compared to all other individuals. Less than 45%, of young male and female top athletes were top level when young. Less than 40% of top level athletes at the age of 16 became top level adults. Discussion. These findings show that the duration of the athlete career influences the personal best performance. Moreover, most of the top level adult athlete were not top level at youth level and most of the top level youth did not maintained the same level of performance in adulthood. We suggest that young age performance do not predict the performance in adulthood because the length of the career is a key factor in the career athlete, however rapid improvements in elite performers are observed from 14 to 18 years of age suggesting that technical learning during puberty is fundamental to develop elite performers. THE VIENNA CPX-TOOL – A NEW ANALYSIS SOFTWARE FOR PERFORMANCE DIAGNOSTICS

ALLEMANN, H., SEILER, P., HAUSHARTER, M., WEBER, C., HEBER, S., POKAN, R.

Institute of Sport Science Vienna

Introduction Vienna CPX-tool is a new software intended for evaluation of cardiopulmonary exercise tests by estimating transitions (T) between 3 phases of energy supply, i.e. T1 and T2. We integrated 3 distinct calculation methods. Each allows estimation of threshold indicators (IND), i.e. lactate turn point 1 (LTP1), ventilatory threshold 1 (VT1) and respiratory equivalent for oxygen (VE/VO₂) for T1 and LTP2, VT2, VE/VCO₂, and heart rate turn point (HRTP) for T2. Since each T is based on a common physiological mechanism, we assume that an accurate calculation method results in a small range of power output estimates for each IND within each T. The aim of the present study was to compare the 3 methods regarding ranges. Methods 10 women and 19 men, mean age 25.3y, performed a bicycle step test until exhaustion with increments of 15 or 20 watt/min, respectively. HR, ventilation (VE), VO₂, VCO₂ were measured continuously, blood lactate concentration (LA) after each stage. Curves for HR, LA, VE, VE/VO₂ and VE/VCO₂ were analyzed by defining sections of each curve, to which each calculation method (Angle, A; Regression, R; Error variance, E) was applied. Sections were set between the start of the work and 75% of maximal power output (Pmax) for LTP1, VE/VO₂, and VT1, between the respective first turn point (TP) and the maximal value of each parameter for LTP2, VT2, and VE/VCO₂, and between 50% of Pmax and HRmax for HRTP. All TPs were computed by 3 methods: A: A point that can move within a predefined section is determined near the center of the calculation section. Two lines, originating in the start and end of the section with a common intersection at the movable point are created. The intersection of lines combination of lines with the highest angle at the intersection is selected, their intersection defines the TP. R: Starting near the center of the dataset, the calculation area is divided into two sections. Applying the least squares method two regression-lines are fitted to the divided areas and the error variance is calculated. This procedure is repeated until the combination of lines with the smallest error variance is identified. The intersection between the two lines marks the TP. E: Two lines are created as in method A. The calculated global error variance is used to identify the two lines with the best fit. The TP equals their common intersection point. Statistics: For each individual, % power output of Pmax was calculated for each IND, the range was calculated for T1 and T2. Range differences between 3 methods were tested by ANO-VAs. Results No differences between methods were found. Conclusion Based on the present findings it is not possible to determine a qualitative difference between the 3 calculation methods. COACHING PRACTICE IN SPORT <5-11 YEARS>: A SYSTEMATIC REVIEW

HOOPER, D.1, HAYMAN, R.1, HALL, E.1

Northumbria University

Introduction: Sport coaching research displays a diverse range of findings, but as interest in the area builds momentum, a call for a logical, organised examination of the literature was required to provide a structured outline of research previously undertaken and any potential lines of enquiry necessary in order to provide a complete overview of sport coaching practice(5-11 years). Therefore, the aim of this paper was to systematically review, evaluate, appraise and synthesise all existing coaching practice literature within sport (5-11 years). The review was undertaken to inform policy and professional practice in sport coaching along with identifying further research opportunities in unexamined areas of coaching. Methods: Initial electronic database searches were directed by the use of specific key words extracted from the research question, which allowed for the main concepts of the review to be investigated. An inclusion and exclusion criteria was developed to aid the efficiency of the acceptance and rejection process. Six major electronic databases and 20 electronic journals were searched in order to identify relevant research. A three stage removal process was undertaken as part of the review and sifting process (Nicholls and Polman, 2007). During the initial phase of sifting, references were removed after reading their title. Abstracts of articles which had not yet been excluded were then read, with further rejections made at this secondary stage of sifting. A full paper review was then completed at this final tertiary stage of sifting and removal process, with the remaining papers being in-

cluded in the final systematic review. Results: After systematically reviewing the extant literature within coaching practice in sport (5-11 years), results indicate that the majority of research undertaken in the area is focused towards an elite setting, with the aim of said research to improve high performance. Furthermore, the research methodology routinely implemented is of a quantitative nature with researchers tending to be from a positivist standpoint on the research paradigm. Discussion: For sport coaching understanding to advance, researchers need to address some of the methodological and contextual inadequacies currently residing within the literature. Giving consideration from a participatory, grassroots environment would provide the profession of sport coaching with a more complete and holistic body of academic work to guide progress. Therefore, findings from the systematic review will be discussed with a focus on their implications for coaches and coach education in grassroots sport. Future studies may wish to examine the underpinning philosophy, values and beliefs of grassroots coaches, with additional consideration given to the practical delivery methods of grassroots coaches supported through systematic observations of grassroots coach delivery. References: Nicholls, A. R., and Polman, R. C. J. (2007) Coping in sport: A systematic review. *Journal of Sports Sciences*. 25(1), p.11-31. Contact: David Hooper: david.hooper@northumbria.ac.uk

MO-SH06 Sport Management

SPORT RELATED ORGANIZATIONS : IMPROVING THE COMPETITIVENESS OF CAREER AND TALENT MANAGEMENT STRATEGIES

CHAUDHURI, S.

University of Physical Education

In the 21st century the issue of career of a sport related organization is becoming an utmost priority due to several reasons. First of all in our rapidly changing dynamic environment it is increasingly difficult for our young generation members to create and develop properly their precise career strategy concept and Hungary is no exception in this context. Secondly the methodology of analysing and utilizing life cycle lessons using a sport mindset philosophy is also a great challenge for HR specialists. Thirdly war for talent in sport related organizations has specific processes and features that deserve more attention from relevant research individuals especially in a globalizing environment. It is understood by the author of this paper that national competitiveness consists of competitiveness of all kind of sectors and industries including sport related industries organizations as follows : • Sport Manufacturing and Sport Retailing Organizations • Sport Professionals Supplement and Sport Complementary Products Organizations • Organizations who either strongly support and/or sponsor sport or have very attractive employee sport benefits • Sport organizations and associations An industry in return has its members striving to obtain and maintain a competitive advantage for as long as possible. Identification and efficient and effective utilization of unique resources and core competencies, transformation of them for a young person using individual talent coaching and Personal Branding methodology has to be ensured for aligning with organizational image and long term job satisfaction. The paper is tending to provide a comparative assessment of efforts made in Hungary in this area to comply with the challenge of in-depth analysis of four above listed area development trends and major key challenges for making sport related organizations an even more substantial contributor to national competitiveness. Evidence will be provided to demonstrate the key challenges and trends to be taken into consideration by any employer sport related organizations willing successfully identify how to reach appropriate job expectations formulated by its stakeholders.

INTEGRATING PEOPLE WITH DISABILITIES IN MAINSTREAM SPORT: A COMPARATIVE ANALYSIS OF ATHLETICS AND SWIMMING

CHRISTIAENS, M.

Coventry University

Introduction In the UK there is an estimate of 10 million people with disabilities. Only around 17.2% of them are active in sport compared to 39.6% of people without disabilities, showing a huge disparity between the two groups. In fact this gap is bigger than the gap related to gender, social class, ethnicity or sexuality. Yet, 65% of people with disabilities is interested in becoming more active and 20% is interested in becoming active (Sport England, 2015). With these positive attitudes towards sport and the huge interest in becoming active, it leaves to wonder what is going wrong. Disability sport has been an under-researched area in both sport and disability studies (Huang, 2005) which is only being addressed in the last couple of years. Therefore, this study is aimed at addressing the existing research gap focusing on disability sport participation, more specific in relation to the recent change in policy with a new focus on integrating people with disabilities in mainstream sport clubs. This study uses a comparative design to look at how grassroots sport clubs are incorporating disability policy within their club strategy. **Methods** This study will compare grassroots sport clubs in Athletics and Swimming. These sports are chosen for their relative big participation rate in the total population, while differing a lot on the amount of people with disabilities participating in them. Swimming has a high participation rate amongst people with disabilities while athletics has a very small participation rate (Sport England, 2015). This study uses a mixed method approach. Quantitative data is collected through an online survey, in order to map the grassroots sport clubs in the West-Midlands (County of the UK) and collect preliminary data. This data will be used to make a selection for a qualitative study. The qualitative study is aimed at gaining an understanding in how grassroots sport clubs implement disability sport policy and if these strategies are efficient. Interviews will take place with multiple stakeholders in the sport clubs. Involving Sport England, board members, coaches and both participants and non-participants. **Discussion** While the data collection is going to take place in the next months, the expectations are that different sport clubs approach the new policy requirements in different ways. It will be interesting to see how strategies of a sport with high participation rates, swimming clubs, compare to a sport with low participation rates, athletic clubs. Secondly it will be very interesting to see how different clubs within the same sport approach the policy in different ways and how this effects participation rates. References Huang, C. (2005). Discourses of Disability Sport?: Experiences of Elite Male and Female Athletes in Britain and Taiwan. Sport England. (2015). Active People Survey 9. London. EFFECTIVE FACTORS ON WOMEN'S PROMOTIONAL IN SPORT MANAGEMENT IN IRAN

EHSANI, M.

Tarbiat Modares University

Introduction: This paper examines women's position in Iran based sports organizations throughout the country. It is argued that the so-called-neutral promotion process is biased against female candidates and in the end, serves the purpose of reinforcing a male-dominated top management (Aitchison, 2003; McKay, 1996; Shew & Arnold, 1998). Methods: The data were collected through self administered questionnaire ($\alpha=.86$) in 2009. The findings of the study reveal several key items in evaluating candidates for promotion. Results: The variables of higher education, organizational commitment, political skills, family support, ICT skills, psychological factors and sport management skills ranked the upper intermediate level for the female managers, but organizational environment stood at the lower level. Discussion: In spite of these factors, women are absent from senior leadership positions and their powerlessness in hierarchy of Iranian sport organization is evidently shown. It is suggested that sport organizations bring about some changes aimed at supporting the women managers in fulfilling their needs.

THE EFFECT OF PHYSICAL ENVIRONMENT AND EMOTIONAL INTELLIGENCE ON PARTICIPATION LEISURE TIME PHYSICAL ACTIVITY

KHANGHOLI, S.

lecturer, Department of Physical Education, Roudehen branch, Islamic Azad University, Tehran, Iran

Introduction Physical environment refers to characteristics of both natural environment (weather, climate, geography) and built environment (community resources, access, information) which may influence people's engagement in PA (Baranowski, 2002). Emotional intelligence has also been defined as: "The ability to perceive and express emotion, assimilate emotion in thought, understand and reason with emotion, and regulate emotion in the self and others" (Mayer, 2000). Leisure-time physical activity (LTPA) refers to "Leisure-time physical activity is exercise, sports, recreation, or hobbies (Centers for Disease Control and Prevention [CDC], n.d.a). Methods The research is regarded as an application one and the methods of data collection is descriptive and correlation, the population on this study included athletic participation in leisure time in Tehran city municipalities regions. Sample size is based on formula for calculating the morgan and kerisi table sample size 152 females and men completed the questionnaire physical environment physical activity leisure time (CDC, 2006) and emotional intelligence bar-on, 2000). the data was analyzed based on multiple regression with the significance level set at 0.05. Results Results indicated that remarkable relationship between the total volume of physical environment and emotional intelligence for athletic participation in LTPA. Physical environment and Emotional intelligence were the independent variables while LTPA was the dependent one. The analysis indicated that only emotional intelligence was correlated ($R=0.74$). liner regression analysis was used to calculate and to examine the effects of the covariates on the associations between physical environment and emotional intelligence to LTPA. those who increased their physical environment from inactive to vigorously active had a significantly compared with the persistently inactive ($RR=0.80$). Discussion Physical environmental correlates of Emotional Intelligence in Tehran city municipalities and investigate environmental moderators of LTPA associations. several researchers have suggested the linear relationship between physical environment and emotional intelligence tend to be mediated by perceived value, which has been empirically supported as an important mediator in the various domains. The current study was designed to fill this void by examining the structural relationships of physical environment and Emotional Intelligence factors in relation to LTPA attendance, while examining the mediating influence of perceived value. References Bar-On, R. (2000), "Emotional and social intelligence: insights from the emotional quotient inventory", Jossey-Bass, San Francisco, CA, pp. 363-88. Retrieved November 16, 2006 from <http://www.cdc.gov/nccdphp/dnpa/physical/terms/index.htm>.

USE TECHNOLOGY ACCEPTANCE MODEL TO EXPLORE THE TRAINING EFFECTIVENESS OF GPS SPORTS WATCH

WU, S.Y., CHOW, H.W.

National Cheng Kung University

In recent years, there has been an increase in the popularity of outdoor exercise. More and more people have begun to enjoy sports like running, triathlons, and trail running. As a result of the boom in wearable technology in the health and fitness area, both recreational and professional athletes have started wearing GPS sport watches, looking to continually monitor their physical activity training and adjust intensities to improve the efficiency of their training. In spite of this trend, the factors of adopting GPS sport watches remain largely unexplored. Hence, this study employed the Technology Acceptance Model (TAM), and added social influence factor as an antecedent variable to examine the factors in influencing the intention behaviors of using GPS sport watches, and ultimately, achieving better training effectiveness. 341 users who had used GPS sport watches in Taiwan responded to a web-based questionnaire. Descriptive statistics, multiple choice analysis, independent t-test, one-way ANOVA, and Structural Equation Modeling (SEM) were used for data analysis. The results were as follows: 1. The majority of users were college-educated men between the ages of 21-40, with regular exercise habits; 2. Users preferred features including accuracy of distance measuring, battery lifetime, watch durability, and heart rate measurement. Additionally, users had an almost universal expectation to be able to track their performance via the GPS sports watch to improve the effectiveness of training; 3. On average, respondents rated higher than the midpoint of 5-points Likert scale in all of the following constructs: "Social Influence (SI)", "Perceived Usefulness (PU)", "Perceived Ease of Use (PEOU)", "Attitude toward Using (AU)", "Behavior Intention (BI)", and "Training Effectiveness (TE)"; 4. There are significant differences between participants who are in training groups or not, in terms of their responses in SI, PU, PEOU, and BI. There are also differences among the times of use per week in terms of SI, PEOU, and BI. 5. The data supports the proposed TAM model with good goodness of fit. The result shows that nearly all of the variables have significant positive effect, except SI to AU and PU to BI. According to the results above, it can promote the recommendations for GPS sports watch manufacturers and future research directions.

ANALYSIS OF CHAOS THEORY MANAGEMENT AT ISLAMIC REPUBLIC OF IRAN YOUTH AND SPORT MINISTRY

ZARGAR, T., HEDAYATI, M.

south Tehran branch, Islamic azad university

The main purpose of this study was to analysis and measurement of chaos theory management at Islamic republic of Iran youth and sport ministry. The method of this study was descriptive-analytic that was conducted survey research. The population of this study con-

sisted of all different sections officials of youth and sport ministry ($N=105$) and sample was selected by Cochran table and the method of sampling was simple random sampling ($n=83$). Measurement scale was self-construct 40 item ($\alpha=0.86$) with 5 point likert. The validity of this questionnaire was confirmed by 15 physical education professors and the reliability of chaos management questionnaire ($\alpha=0.86$). In order to data analysis kolomogrove-smirnove, pearson correlation coefficient, one sample t test, one way ANOVA and Test-Tukey was used in $P \leq 0.05$. The results indicate that there is significant difference between expected mean with experimental mean of chaos management of officials of youth and sport ministry and its subscales. Also, there is significant difference between butterfly effects according to educational certification. Moreover, there was significant difference between Bachelor of Science degrees with master of art. At least, given to low level of chaos management and its subscales among youth and sport ministry officials it suggests that with holding special meetings on ministry emphasized on significant of chaos management on youth and sport ministry.

THE EVALUATION OF SERVICE QUALITY OF RECREATIONAL ANIMATION ACTIVITIES

ÇEVİK, H., SIMSEK, K.Y.

Anadolu University, Faculty of Sport Science

Introduction The well-organized recreational animation activities play such a significant role in clients' repeating their buying behaviors and also they lead the clients to prefer the same enterprise again for their prospective travels to enjoy recreational activities. Therefore, it is of great importance to be aware of the quality of the service rendered .The purpose of this research is to assess the service quality of the recreational animations held in five-star hotels. **Methods** The population of the research is composed of the tourists that stay in the five-star hotels which are located in Antalya. The sample population is selected using the convenience sampling method and includes in total 603 participants. "Scale of Service Quality in Recreational Sport" (SSQRS), developed by Ko and Pastore (2005), has been used as the data collection tool of the research. Descriptive statistics, T-test analysis and One Way ANOVA analysis have been benefited so as to analyze the data. **Results** The sample population of study consisted of 324 (53.7%) female and 279 (46.3%) male. 177 (29,4%) Turkish citizen, 159 (26,4%) German citizen, 136 (22,6%) Russian citizen and 131 (21,7%) other countries citizen were included in study It was detected that the participants attended study ranged mostly between 28-34 (%25,7) age. The most of participants (%57) had undergraduate level. The widest participation in terms of occupation was by self-employed (17,2%). Individuals with an income between 1001 \$ -2000 \$ (17,9%) ensured the widest participation in terms of income levels. Additionally, it was seen that there were significant differences according to demographic characteristics of sample group in all dimensions that affected the service quality. **Discussion** It has been observed that the participants with high income have a high average from the aspects of program quality, physical environment, satisfaction and access to information. Moreover, it has been found out that the participants of the group of younger age have a high average from the aspects of result, satisfaction and access to information. Also it has been determined that the graduates have a high average about the results obtained from the recreational animation activities as do the participants of the profession group of administrators from the aspects of program and as also do the students from the aspects of physical environment, satisfaction and access to information. Finally the assessment of recreational animation activities according to nationalities shows that the Turkish nationals have a low average in all dimensions. **Keywords:** Service Quality, Recreation, Animation **References:** Ko Y. J. and Pastore D. L. (2005). A Hierarchical Model of Service Quality for the Recreational Sport Industry, Sport Marketing Quarterly, 14, 84-97.

THE RELATIONSHIP BETWEEN PERCEIVED SERVICE QUALITY AND LOYALTY: RECREATIONAL SPORTS FACILITIES ORIENTED RESEARCH

BAYRAM, A., MERCANOGLU, A.O., TURGUTKAYA, K., KOSE, H.

Anadolu University, Faculty of Sport Sciences

Introduction Service quality and customer loyalty is regarded as an important factor in terms of recreational sports facilities. The aim of this study is to uncover the relationship between the service quality and loyalty of recreational sports facility users. This study can be a guide to companies in terms of recreational consumer behaviours. **Methods** Survey used in this study was performed on 205 customers in five different sports facilities in Eskisehir. The scale, which was developed by Zeithaml et al. (1996) used in this study. **Results** It can be said that there is a direct correlation between quality of service and customer loyalty. Exploratory factor analysis has revealed two sub-dimensions. The scale consists of 13 items and its reliability coefficient value (cronbach's Alpha) is 0.855. The values over 0.70, can be applicable (Nunnally, 1978). An item that had less than 0.50 factor value was removed from the scale. **Discussion** The original study consists of a total of 4 sub-dimensions. Those sub dimensions are "word of mouth communication", "purchase intentions", "price sensitivity" and "complaining behavior". However, in our study, 2 sub-dimensions have emerged. The cultural diversity and the properties of the universe are thought to be the cause of this situation. While the items of "Word of mouth communication" and "purchase intentions" sub-dimensions are concentrated in one sub dimension; the items of "price sensitivity" and "complaint behaviour" sub-dimensions are concentrated in another sub-dimension. **References** Nunnally, J. (1978). Psychometric Theory (Second edition). New York: McGraw Hill. Zeithaml, V. A., Berry, L. L. & Parasuraman, A. (1996). The behavioral consequences of service quality. REFORM OF GOVERNANCE STRUCTURE OF SMALL SIZE FA REACTING TO GOVERNANCE CHALLENGES OF XXI CENTURY

EIMONTAS, E., VALENTINE, I., STASKEVICIU-BUTIENE, I.

Lithuanian Sports University

Shifting political-social-economical-cultural poles within Europe and beyond require sporting bodies to consider whether existing inclusive policies, diversity strategies and levels of representation across all groups remain appropriate and reflective of their participants and society in general. Stakeholders of sport have a greater interest to participate in the future direction and policy making activities of sports governing bodies and to have their views heard and appropriately reflected in the decisions of those bodies. The purpose of this survey was to propose governance framework for the sport organization, whereas at the heart of compiling the proactive model is stakeholders' management improving governance and effectiveness of the organization through representation of stakeholders and their involvement in decision making. **Findings:** governance has direct relationship with performance since it is very important how efficiently the decisions in the sport organization are taken, there is a governance problem in the Lithuanian Football Federation (LFF) since the organization doesn't have a proper governance structure to tackle with contemporary challenges achieving organizational objectives through co-opting with all stakeholders. Though the LFF main goal is to preserve eco-system whereas its members and stakeholders could perform

their activities, usually the LFF acts as the main actor instead of coordinator; in sport expected outcomes are defined by much more multi-faceted objectives and performance indicators, sometimes having nothing to do with financial performance of the organization – higher levels of participation, sporting results of the national team, success for clubs, grassroots development, etc.; though there are practices of informal stakeholders' cooperation through external mechanisms among the sport organization, when reforming the governance structures of small size sport organization inclusion of the stakeholders in the governance structures shall be evolutionary step by step because of uncertainty and opposition; the proposal for external mechanisms was mentioned by majority of the respondents when instead of speaking about stakeholders' involvement into the official structures of the sport organization, there should be adverse involvement pursued; the governance in the sport organization is shifting from the classic unilateral vertical channels of authority of the pyramidal network towards new lateral forms of networked governance; international sport organizations should be important players in the development of practices and the governance structures and implementation of governance networks in their member associations; the governments will play more and more important role in the sports, therefore the inclusion of it into the governance structures are beneficial for the sport organizations.

DETERMINING AND EVALUATING DIMENSIONS OF CUSTOMER RELATIONSHIP MANAGEMENT IN SPORTS FACILITIES: SAMPLE OF ESKİSEHIR

MERCANOGLU, A., BAYRAM, A., TURGUTKAYA, K., KOSE, H.

Anadolu University Faculty of Sport Sciences

Introduction It can be said that Customer Relationship Management (CRM), which has emerged through the efforts of organizations that want to gain their potential customers, has an important role for sports facilities. Therefore, the aim of this study was to determine and evaluate dimensions of CRM in sports facilities. Methods In order to determine dimensions of CRM approach that perceived by sports facility customers in our country, the scale which was developed by De Wulf et al. (2001) applied to the sports facility customers. The research group consists of 198 sport facility customers in total who were chosen with convenience sampling method. Exploratory factor analysis was used to determine factor loads. Results As a result of exploratory factor analysis six dimensions were revealed. These dimensions are named as relationship quality, customer orientation, communication by mail/sms, activities, preferential treatment, continuity. Three items was removed because of their factor load values ($< 0,50$). Discussion It can be said that due to cultural and industry differences, there are two important differences between original scale's dimensions and our study results. The first one, most of items which belongs to "trust", "relationship commitment", "relationship quality and relationship satisfaction" dimensions are grouped under "relationship quality" dimension. The second one, items which belongs to "interpersonal communication" and "perceived relationship investment" dimensions are grouped under "customer orientation" dimension. IS-PM01 Taking care of the respiratory health of elite athletes

MECHANISTIC BASIS OF 'ASTHMA' IN ATHLETES

KIPPELEN, P.

Brunel University London

Asthma is the most common chronic medical condition in elite athletes, with a prevalence of 8% (Fitch, 2012). Exercise is a potent trigger of asthma attacks, and the transient airway narrowing brought about by (strenuous) exercise is commonly referred to as exercise-induced bronchoconstriction (EIB). The aim of this presentation is to discuss the various mechanisms potentially implicated in the short- and long-term development of asthma / EIB in elite athletes. While local, airway osmotic and thermal stress associated with exercise-hyperpnoea are key determinants to EIB (Anderson & Daviskas, 2000), the role of whole-body dehydration in precipitating airway narrowing post-exercise is unknown. Novel data suggest a detrimental effect of mild-to-moderate exercise-induced dehydration on resting lung function (with possible gas trapping and small airway collapse) in athletes, but no significant effect of mild fluid losses (~2% of body weight) on bronchial responsiveness. Further, while repeated-injury repair of the airway epithelium induced by acute osmotic and / or mechanical stress during exercise-hyperpnoea is thought to contribute to the pathogenesis of asthma / EIB in elite athletes (Anderson & Kippelen, 2005), our understanding of the role of other contributing factors – such as (over-)use of nutritional supplements – is limited. Our preliminary data highlight the potential for the widely used ergogenic supplement, creatine monohydrate, to increase lung inflammation and airway responsiveness in youth, elite, football players (particularly, in those with atopy). Further work is now warranted to confirm these preliminary findings and to explore the mechanisms through which creatine, when associated with intensive physical training, might up-regulate airway inflammation in the human lung. In summary, it is important to recognise that asthma / EIB is a widespread, serious, but manageable condition in elite athletes. Based on our current understanding of the pathophysiology of asthma / EIB in athletes, appropriate pharmacological and non-pharmacological prevention strategies should routinely be implemented to minimise the impact of these respiratory disorders on athletes' health and performance. THE PROS AND THE CONS OF ENGAGING IN COMPETITIVE SWIMMING: A LUNG HEALTH PERSPECTIVE

BOUGAULT, V.

Université Droit et Santé Lille 2

Swimming is a sport usually considered as non asthmogenic. The warm and humid atmosphere of indoor swimming pools limits the airway dehydration associated with the high ventilatory demand of this endurance-based activity, therefore reducing the risk for exercise-induced bronchoconstriction (EIB)^{1,2}. When asthma is well managed, asthmatic athletes perform as well as their non-asthmatic peers, and famous Olympians (including swimmers) are well-known asthmatics. However, amongst non-asthmatic endurance athletes, swimmers are the ones who develop more frequently asthma-related disorders during their career. Repeated airway inflammation and epithelial damage during strenuous and repeated training sessions are thought to be mainly responsible for airway hyper-responsiveness in elite swimmers^{1,2}. Many recent studies also highlight an increased incidence of asthma in lifeguards and in children regularly exposed to the atmosphere of chlorinated swimming pools^{1,2}. Thus, regular exposure to chlorine by-products could be a contributing factor to the high prevalence of asthma-related disorders in elite swimmers. The current dilemma is to establish whether swimming is a 'safe' activity for those who compete at top level, and to devise appropriate prevention strategies to protect the respiratory health for all those who swim^{1,2}. 1. Is there a potential link between indoor chlorinated pool environment and airway remodeling/inflammation in swimmers? Expert Rev Respir Med 2012;6(5):469-71

INHALERS FOR AIRWAY HEALTH OR ERGOGENIC AID?

DICKINSON, J.

University of Kent

Athletes are more susceptible to asthma and exercise induced bronchospasm (EIB) than non-athletes (Dickinson et al., 2011). However, the treatment of athletes with asthma/EIB is not always consistent or optimal. Athletes with asthma/EIB who train and compete using sub-optimal inhaler therapy are susceptible to airway remodeling, worsening of symptoms, increased reliance of rescue medication and increased severity of their condition (Karjalainen et al., 2000). Secure diagnosis and appropriate management will ensure airway health is optimised in athletes with asthma/EIB (Parsons et al., 2013). Since 2010, the World Anti-Doping Agency (WADA) has removed the requirement for an athlete with asthma/AHR to obtain a Therapeutic Use Exemption Certificate in order to use some inhaled β 2-Agonists (IBAs). There is a danger that unscrupulous athletes may use IBAs to seek a competitive advantage. IBAs does not appear to enhance endurance performance (Pluim et al., 2011). However, emerging evidence suggests sprint and power performance may be enhanced from using IBAs (Kalsen et al., 2016). This session is relevant for sports medicine professionals and sport and exercise scientists. Delegates will gain an understanding of the best practice in the treatment athletes with asthma/EIB. Delegates will learn how IBAs may impacts on the performance of athletes. References: Dickinson J, McConnell A, Whyte G. Br J Sports Med. 45, 1126-31. Introduction: Dietary nitrate supplementation has previously been shown to enhance exercise performance in moderately-trained endurance athletes. Recent work also suggests increases in repeated sprint and/or intermittent high-intensity exercise performance following nitrate supplementation, relevant for team-sports. We assessed the effects of 6 days of nitrate supplementation on high-intensity intermittent type exercise performance in trained soccer players. **Methods:** Thirty-two trained soccer players (23±1 y; 2nd and 3rd Dutch amateur league) participated in a double-blind, randomized, placebo-controlled cross-over experiment. Following a familiarization trial, all subjects participated in 2 separate test-days in which intermittent exercise performance was assessed using the Yo-Yo intermittent recovery level 1 test (Yo-Yo IR1). Test days were preceded by 6-days of concentrated nitrate-rich beetroot juice ingestion (140 mL; providing ~800mg nitrate/day; BRJ), or a nitrate-depleted beetroot juice (PLA), with the last supplemental bolus being ingested 3 h prior to performing the Yo-Yo IR1 test. A single blood sample was collected ~2.5 h after ingestion of the last supplemental bolus to determine pre-exercise nitrate and nitrite concentrations. Supplementation periods were separated by 1 week washout. The primary outcome was distance covered in the Yo-Yo IR1 test. Additionally, heart rate (HR) was measured continuously throughout the test, and ratings of perceived exertion (RPE) were assessed using the Borg-20 scale. All data were analyzed using paired samples t-tests. Plasma and saliva nitrate and nitrite concentrations represent preliminary data from n=24. Data are presented as mean ± SEM. **Results:** Plasma nitrate and nitrite concentrations were significantly increased following 6 days of BRJ supplementation (836±44 µM and 581±45 nM) when compared to the PLA trial (72±5 µM and 165±14 nM; both P<0.001). Distance covered in the Yo-Yo IR1 test was 3.4±1.3% greater with BRJ (1623±48 m) when compared to PLA (1574±47 m; P=0.027). Mean HR was significantly lower with BRJ vs PLA (172±2 vs 175±2; P=0.014). Peak HR (190±1 vs 191±1), and RPE (17.3±0.4 vs 17.6±0.3) did not differ between BRJ and PLA. **Conclusion:** Six days of beetroot juice supplementation increases plasma nitrate and nitrite concentrations and improves performance during an intermittent type exercise task in soccer players. "FIFA 11+ KIDS" A WARM-UP PROGRAM TO PREVENT INJURIES IN CHILDREN'S FOOTBALL: CLUSTER RANDOMISED CONTROLLED TRIAL

RÖSSLER, R.1, BIZZINI, M.2, DVORAK, J.2,3, CHOMIAK, J.4, AUS DER FÜNEN, K.5, VERHAGEN, E.6, LICHTENSTEIN, E.1, BEAUDOUIN, F.5, JUNGE, A.2,7, FAUDE, O.1

University of Basel

1: University of Basel (Switzerland), 2: F-MARC and Schulthess Clinic (Zürich, Switzerland), 3: FIFA (Zürich, Switzerland), 4: Charles University (Prague, Czech Republic), 5: Saarland University (Saarbrücken, Germany), 6: University of Amsterdam (The Netherlands), 7: Medical School Hamburg (Germany) Introduction The prevention of football injuries should start at a young age (Rössler et al., 2014). Based on epidemiological data (Rössler et al., 2016b), the injury prevention program FIFA 11+ Kids was developed (Rössler et al., 2016a). The objective of the present study was to assess the effectiveness of FIFA 11+ Kids with regard to injury prevention. Methods Children's football teams (under-11 and under-13 age groups) from Switzerland, Czech Republic, The Netherlands, and Germany were recruited. Clubs were randomised to an intervention (INT) and a control group (CON), and followed for one season. INT performed FIFA 11+ Kids during their warm-up, while CON warmed-up as usually. Data was collected using an internet-based registration platform. Time-to-injury data were analysed, and hazard ratios (HR) calculated using extended Cox models to account for correlations on team- and intra-person-level. Results In total, 3,895 player seasons and 292,749 hours of football exposure were recorded. Mean age of players was 10.8 (SD 1.4) years. During the study period 374 (INT=139; CON=235) injuries occurred. Overall injury rate in INT was reduced by 48% compared to CON (HR 0.52; 95%-CI 0.32–0.86, P=0.01). Further reductions of injury rates were found with regard to match (49%, (HR 0.51; 0.27–0.94), P=0.03), to training (42%, (HR 0.58; 0.38–0.89), P=0.01), to severe (74%, (HR 0.26; 0.10–0.64), P=0.003) and to lower extremity injuries (55%, (HR 0.45; 0.24–0.84), (P=0.01). Discussion FIFA 11+ Kids is effective in reducing injuries in children's football. Considerable effects were found for overall, match, training, lower extremity, and specifically severe injuries. The present overall injury reduction is comparable to studies in older youth football players (Rössler et al., 2014). The reduction of injury incidence might be due to improved motor performance (Rössler et al., 2016a). A broad implementation may help to reduce injuries and to support the health benefits of playing football in the long term. The authors gratefully acknowledge the financial support of FIFA. REFLECTIONS FROM A FEMALE SPORT PSYCHOLOGIST WORKING IN ELITE LEVEL PROFESSIONAL FOOTBALL

FRANCESCA, C., NESTI, M.S., TOD, D., LITTLEWOOD, M.A.

Liverpool John Moores University

Introduction The introduction of the Elite Player Performance Plan (EPPP) by the English Premier League in 2011 has resulted in more opportunities for sport psychology practitioners within Academy football. It is anticipated that more female sport psychology practitioners will join the sport and deliver psychological support at youth levels. However, few practitioners are currently writing about their experiences, and the challenges they have faced within this culture. The aim of the study was to outline a range of experiences that shaped the identity of a female sport psychology practitioner working in elite level professional football. Methods An ethnographic study was conducted over a 24-month period (3-4 days per week) within an elite level professional football club. The first author's role within the club was a practitioner-researcher, delivering sport psychology support to Academy footballers and support staff. Data was collected via participant observation, and field interviews (Hammersley & Atkinson, 1995). Data is presented in a series of progressive vignettes based upon critical moments that shaped the researcher's development as a neophyte sport psychology practitioner. Results and Discussion The findings from this study fall within the following themes; "Where it all began", "11 months on; The same old story", and finally "Learning to cope". The first two themes outline challenges that the practitioner faced in developing a relationship with a senior member of staff in a culture where power, dominance, and control are paramount. A number of encounters left the practitioner questioning her belonging at the club, and more importantly her identity and future as a sport psychology practitioner. The final theme "Learning to cope" outlines how after 12 months the practitioner started to navigate her way through these challenges. An existential perspective is used to frame the experiences. The practitioner's feelings of isolation were related to a lack of understanding, and an estrangement of meaning from the situations encountered. However, existentialists take a positive stance on this, and believe that recognition of the feelings associated with isolation are a pre-requisite for inner growth, and attaining greater self-knowledge (Kierkegaard, 1983). It was through reflection, frequent supervisory meetings and professional training that the practitioner began to feel more comfortable with her experiences, and began to understand the individual's behaviour. MENTAL FATIGUE IMPAIRS SOCCER-SPECIFIC PERFORMANCE

SMITH, M.1,2, MARCORA, S.3, LENOIR, M.2, BADIN, O.1, MERLINI, M.3, DEPREZ, D.2, ZEUWTS, L.2, COUTTS, A.1

1: UTS (Australia), 2: UGent (Belgium), 3: University of Kent (UK)

Introduction: Anecdotal reports from soccer players and coaches suggest that mental fatigue impairs soccer performance. However experimental investigations of this claim are limited. Therefore, two randomised, crossover investigations were conducted to assess the impact of mental fatigue on soccer-specific physical, technical, and decision-making performance. Methods: Players completed a 30-min Stroop task (mental fatigue treatment), or 30 min of an emotionally neutral control, prior to tests of soccer-specific performance. Study 1 assessed the impact of mental fatigue on physical and technical performance of 20 well-trained soccer players during 15-min, 5 vs. 5 small-sided games (SSGs). Physical performance was assessed using 15-Hz GPS units, and technical performance was assessed using video-based notational analysis. Heart rate (HR) and ratings of perceived exertion (RPE; CR10) were also recorded during the SSGs. Study 2 utilised videos of simulated play to assess the impact of mental fatigue on soccer-specific decision-making, and visual search behaviour in 12 well-trained soccer players. Decision-making skill was assessed using response time and accuracy, while visual search behaviour was assessed via search rate, fixation location, and fixation order. A progressive magnitude-based approach was used to assess chances of differences between conditions being trivial or true (greater than the smallest worthwhile change; $0.2 \times \text{the between-subjects SD}$). Results: Players reported higher levels of mental fatigue following the Stroop task than the control treatment in both studies, while no clear differences in motivation existed. Mental fatigue had unclear effects on most physical performance variables in Study 1, despite a possibly lower HR (mental fatigue = $85 \pm 5\%$ HRmax; control = $86 \pm 4\%$ HRmax; ES = -0.28), and likely higher RPE in the mental fatigue

condition (mental fatigue = 6.8 ± 1.4 ; control = 6.2 ± 1.6 ; ES = 0.39). In contrast, mental fatigue impaired both offensive and defensive technical performance during the SSGs (positive involvements: mental fatigue = $70 \pm 10\%$; control = $63 \pm 9\%$; ES = -0.73). In Study 2, mental fatigue very likely reduced soccer-specific decision-making accuracy (mental fatigue = $81 \pm 6\%$; control = $86 \pm 4\%$; ES = -0.89) and likely increased response time (mental fatigue = 768 ± 134 ms; control = 685 ± 156 ms; ES = 0.49), despite minimal differences in visual search behaviour. Discussion: These findings support anecdotal reports that mental fatigue impairs soccer-specific performance. Soccer clubs may benefit from assessing pre-match routines, to ensure players are not mentally fatigued prior to competition, and are advised to identify and implement strategies that may attenuate the negative impact of mental fatigue on performance. In this respect, coaches could utilise short SSGs to train technical performance under mentally fatigued conditions, without compromising physical training loads. Contact Mitchell.Smith@uts.edu.au

THE DETERMINATION OF ENERGY COSTS DURING SOCCER MATCHES: COMPARATIVE ANALYSIS BETWEEN MEASURED AND CALCULATED ENERGY EXPENDITURE

VENZKE, J., NARDIELLO, D., PLATEN, P.

Ruhr-University Bochum

Introduction: The metabolic demands of soccer and other team sport players have been a subject of research for many years. However, there is no method for estimating the energy costs (EC) during official matches. A new mathematical approach can be used to calculate metabolic loads during a match. Using this method it might be possible to determine EC from velocity and acceleration data measured by global positioning system (GPS) or comparable technology. The aim of the study was to validate the new mathematical approach for the determination of metabolic demands by comparing the results of the mathematical analysis against the direct measurement with spiroometry (SM) during a soccer match. Methods: 22 healthy soccer players from the 5th German League agreed to participate in a simulated soccer match with a playing time of 90 min and a regular halftime break (15 min). 8 of the subjects (24.4 ± 2.1 y, 183.3 ± 6.9 cm, 82.6 ± 8.0 kg) wore a portable GPS system (GPI-Sports, 5 Hz) for the determination of accelerations and decelerations and velocities, and additionally a portable SM system. GPS and SM data were recorded simultaneously to compare direct vs. indirect determination of EC. The match was separated into four quarters to acquire an accurate analysis. Data was analyzed by means of a paired t-test and Pearson's chi-squared test. Results: EC determined by the mathematical approach underestimated directly determined EC by approximately 25% and was significantly lower compared to the directly determined EC (1030 ± 287 vs. 779 ± 171 kcal, $2p < 0.05$ for directly measured and calculated EC, respectively). The correlation between the calculated and directly measured EC was highly significant for the total game ($R = 0.88$), the two halves ($R_{1st} = 0.85$, $R_{2nd} = 0.96$), and the last two quarters ($R_{3rd} = 0.97$, $R_{4th} = 0.91$) ($2p < 0.01$). Discussion: Data showed that the determination of EC of a soccer match based on acceleration and velocity data using a new mathematical approach seems to be possible and valid however the results still underestimate the real energy costs. Correction factors are required for an even better approximation to the real EC, including corrections for movements with the ball, passing the ball, shots, jumps, and taking into account different ground conditions. Further studies will result in nearly exact estimation of EC of soccer matches and will help to optimize training loads. References: 1. di Prampero, P. E., Fusi, S., Sepulcri, L., Morin, J. Invited symposia**IS-PM02 Nutritional supplements to improve health and performance****FUNDAMENTAL AND EMERGING CONCEPTS IN THE REDOX REGULATION OF EXERCISE RESPONSES AND ADAPTATIONS**

NIKOLAIDIS, M.

Aristotle University of Thessaloniki

Although substantial progress on the understanding of the molecular functions of reactive oxygen, nitrogen and sulfur species ("reactive species") has been attained *in vitro*, this has rarely been translated *in vivo*. The equivocal role of reactive species in exercise adaptations is an example showing the inadequacy of current redox biology research to shed light on fundamental biological processes *in vivo*. In fact, despite intense research efforts, it is still uncertain whether and how reactive species regulate exercise-induced responses and adaptations. This is mainly due to the extreme complexity of *in vivo* biology. Contrary to the complexity and specificity of the redox network, the most common approach to establish the role of reactive species in exercise responses and adaptations is the measurement of oxidative stress biomarkers in blood or muscle. However, the use of such generic biomarkers does not provide mechanistic information (Margaritelis et al. 2016). Another frequent methodological choice is to exogenously administer pleiotropic compounds with purported generic antioxidant properties (principally vitamin C and E), aiming to decrease global reactive species levels and, thus, to attenuate exercise-induced oxidative stress. However, there is a paucity of evidence supporting the notion that antioxidant supplementation interferes with exercise-induced redox signaling via a redox-dependent "scavenging" mechanism. To describe as accurately as possible the biological role of reactive species, our group has proposed six fundamental principles that should be considered to mechanistically link reactive species production to exercise responses or adaptations: 1) identify and quantify the reactive species, 2) determine the potential signaling properties of the reactive species, 3) detect the sources of reactive species, 4) locate the domain modified and verify the (ir)reversibility of post-translational modifications, 5) establish causality between redox and physiological measurements, 6) use selective and targeted antioxidants (Margaritelis et al. 2015). Fulfilling these principles in their entirety requires an idealized human experimental setting, which is certainly a utopia. However, I believe that an account of the complexity of redox reactions in future research will reveal that redox processes are behind most (if not all) exercise responses and adaptations. I foresee that exercise redox biology will be one of the true frontiers in the exercise physiology research for the 21st century. A FISHY STORY THAT KEEPS REPEATING : OMEGA-3 DERIVED LIPID MEDIATORS, DO THEY HAVE A BENEFICIAL ROLE FOR THE PATIENT AND THE PERFORMER ?

LINDLEY, M.R.

Loughborough University

A variety of fatty acids exists in the bloodstream and in the cells and tissues of humans with some being endogenous (non-essential) alongside some important exogenous fatty acids (essential – dietary). Fatty acids can be energy sources or membrane constituents and have biological activities that influence cell and tissue metabolism, function, and responsiveness to hormonal and other signals. Biological activities can be grouped as regulation of ; membrane structure and function, intracellular signalling pathways, transcription factor activity, and gene expression; alongside the production of bioactive lipid mediators. Through these effects, fatty acids influence health, well-being, and disease risk and possibly response to exercise and training. Although traditionally most interest in the health impact of fatty acids related to cardiovascular disease, it is now clear that fatty acids influence a range of other diseases, including metabolic diseases such as type 2 diabetes, inflammatory diseases in general and cancer specifically. Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are omega-3 (n-3) fatty acids found in oily fish and fish oil supplements. EPA gives rise to eicosanoids that often have lower biological potency than those produced from arachidonic acid (AA) while both EPA and DHA give rise to new families of anti-inflammatory and inflammation resolving mediators called resolvins, protectins and maresins. Identification and structural elucidation of these new families of bioactive mediators in resolution has opened the possibility of diverse patho-physiologic actions in several processes including infection, inflammatory pain, tissue regeneration, neuroprotection-neurodegenerative disorders, wound healing, and others. This presentation will take us on a journey from dietary supplementation through tissue incorporation and into biological action as linked to both disease and sporting performance.

POLYPHENOLS: PANACEA OR PARIAH FOR HUMAN HEALTH AND PERFORMANCE

BOWTELL, J.

Exeter University

Epidemiological evidence demonstrates the many health benefits associated with fruit and vegetable consumption including reduced risk of and mortality from cardiovascular disease, and this is attributable at least in part to their phytochemical content. Polyphenols containing at least one phenolic ring and 2 or more hydroxyl groups can be classified into 5 main families. The most plentiful and widely expressed in plants are the flavonoids which include sub-families such as anthocyanins (cherries and berries), and flavanols (cocoa). These substances have been shown to: (i) inhibit key reactive oxygen species producing enzymes such as NADPH oxidase, (ii) improve endogenous anti-oxidant capacity perhaps via signalling through nuclear factor erythroid 2-related factor (Nrf2), (iii) inhibit cyclo-oxygenase 1 and 2, also the target of non-steroidal anti-inflammatory drugs, (iv) enhance endothelial dependent vasodilatation and (v) stimulate mitochondrial biogenesis in skeletal muscle. It is plausible therefore that polyphenol consumption may protect against age-related decline in cardiovascular, musculoskeletal and cognitive function, as well as interacting with exercise training adaptation, but data from polyphenol supplementation studies with human participants are relatively sparse. Muscle damage subsequent to intense exercise is caused partly by the mechanical forces to which the muscle is exposed, but reactive species and inflammatory processes are also suggested to be important contributors to the damage. We and others have shown that fruit-derived polyphenol supplementation enhances recovery from muscle damage, but very few studies have investigated the consequences for training adaptation. For older adults, resistance to the anabolic effects of protein and exercise is a key factor in sarcopenia. As well as physical inactivity, low grade inflammation and oxidative stress may contribute to this important problem that leads to loss of function and capacity for independent living. We will present our data examining whether fruit-derived polyphenols can influence the anabolic response in the elderly. Exposure of the vasculature to ROS and RNS is suggested to contribute to endothelial dysfunction, and acute and chronic consumption of fruit-derived polyphenols have been shown to improve peripheral vascular function possibly via improved nitric oxide bioavailability. We have recently shown that chronic blueberry consumption is able to increase resting state brain perfusion as well as improving task related brain activation in healthy older adults, offering the potential to support improved cognitive function. Cherries and berries may truly provide a tasty panacea for healthy aging.

Invited symposia

IS-PM03 Oxygen Uptake Kinetics in Performance, Health and Disease

VO₂ KINETICS: CONTROL AND RELATIONSHIP TO PERFORMANCE

JONES, A.M.

Exeter University

The kinetics of pulmonary O₂ uptake following the onset of exercise provides important insights into the integrated adjustment of the pulmonary-cardiovascular-muscle metabolic systems to meet an increased energy demand. While the control of VO₂ kinetics is complex and continues to be investigated, the rate of adjustment of mitochondrial oxidative phosphorylation is functionally linked to the rate of cytosolic high-energy phosphate hydrolysis, such that the principal limitation appears to be an intrinsic inertia of intracellular processes. In other situations, such as when type II fibres are recruited during high-intensity exercise or there are cardiovascular impediments, substrate supply (in the form of O₂) may further limit the VO₂ on-kinetics. During moderate-intensity exercise, VO₂ typically attains a steady state within 2-4 minutes; however, during heavy- or severe-intensity exercise, VO₂ continues to rise with time despite a constant external power output. This greater O₂ cost of exercise, reflected in the 'VO₂ slow component' phenomenon, signifies a loss of skeletal muscle efficiency. The VO₂ profile during exercise has important implications for the development of fatigue and exercise intolerance. For example, the magnitude of the O₂ deficit that is incurred during the first 1-2 minutes of exercise, and which is a function both of the VO₂ time constant and amplitude, will determine the extent to which substrate-level phosphorylation is activated with implications for high-energy phosphate depletion and hydrogen ion accumulation. Also, the trajectory of the VO₂ slow component during higher-intensity constant-work-rate exercise will dictate the time to exercise intolerance because exhaustion becomes imminent after the maximum VO₂ has been attained. Understanding VO₂ kinetics and its relationship to fatigue development enables sport scientists to consider

interventions which might enhance the VO₂ kinetic profile (i.e., speed the initial response or attenuate the subsequent slow component) and thus improve sports or exercise performance. This presentation will consider several such interventions including training, prior exercise, pacing and nutritional supplementation. Contact a.m.jones@exeter.ac.uk

VO₂ KINETICS IN HEALTH VERSUS HEALTHY AGING AND DISEASE

POOLE, D.C., JONES, A.M., MUSCH, T.I.

Kansas State University

Slow VO₂ kinetics, emblematic of loose metabolic control, "sows the seeds" for exercise intolerance by accelerating depletion of finite high energy phosphates and intramuscular glycogen reserves. There is compelling support for VO₂ kinetics in young healthy individuals being limited by mitochondrial inertia rather than VO₂ delivery per se. However, exercise that recruits more fast twitch muscle fibres and/or cardiovascular dysfunction consequent to aging and also diseases such as heart failure, diabetes or emphysema can predilect O₂ delivery-limited VO₂ kinetics (Poole and Jones, 2012; Hirai et al. 2015). For muscles that are O₂ delivery-limited the local O₂ delivery (QO₂)-to- VO₂ ratio assumes a key point of metabolic control as this sets the microvascular O₂ partial pressure (PmvO₂) and thus the potential for blood-myocyte O₂ flux. At least in animal muscles during contractions PmvO₂ is far lower in fast twitch muscles than in their slow twitch counterparts and is lowered in mixed fibre-type muscles by aging, heart failure and diabetes (rev. Poole et al. 2012). Exercise training and other therapeutic interventions such as sildenafil/tadalafil (Viagra/Cialis) that act to promote vasodilation (via nitric oxide dependent or independent means) elevate muscle PmvO₂, speed O₂ kinetics and increase exercise tolerance (Sperandio et al. 2011; Hirai et al. 2015). Accordingly, therapeutic interventions that effectively increase QO₂ in exercising muscles would at first glance seem to be overwhelmingly beneficial. Unfortunately, the reality is more complex. Within and among exercising muscles there is a considerable heterogeneity of QO₂s, O₂ s and QO₂: O₂ (PmvO₂) ratios (Koga et al. 2014). Whereas elevating QO₂ and thus PmvO₂ in one region may have beneficial metabolic effects in that region, if the "extra" QO₂ creates a QO₂ deficit elsewhere or, alternatively, demands an overall greater cardiac output that jeopardizes cardiac integrity the end result would be counterproductive to exercise tolerance. The frontier and substantial potential of this rapidly-moving field will be explored especially as it relates to improving exercise tolerance and quality of life in aging and patient populations. VO₂ KINETICS IN DIFFERENT MODES OF EXERCISE

SOUZA, A.1,2, VILAS-BOAS, J.P.1,2, FERNANDES, R.J.1,2

CIF2D, Faculty of Sport (University of Porto, Portugal); LABIOMEP (University of Porto, Portugal)

Introduction The rate at which a subject can "switch on" their aerobic energy system to fulfil the requirements for exercise performance can determine if the subject will fatigue less rapidly and be better able to sustain the demands of that particular task. Thus, oxygen uptake (VO₂) kinetics can be considered to involve the study of the physiological mechanisms responsible for the dynamic VO₂ response to exercise, determining the instantaneous aerobic and anaerobic energy transfer, the mixture and amount of substrate utilized, and the tolerable duration of exercise (Jones & Burnley, 2009). One of the key considerations when measuring VO₂ kinetics is that the VO₂ response to exercise can be altered considerably when different ergometers or modes of exercise are used. The first study that compared the VO₂ kinetics in different exercise modes demonstrated that the half time (time necessary to achieve 50% of the total VO₂ response) for the on-transient phase was longer at the same absolute metabolic requirement for arm cranking compared to cycling, although it was similar at the same relative exercise intensity (Cerretelli et al., 1977). Since this first study, the majority of research has been conducted using cycle ergometry and treadmill running and within the heavy and severe exercise intensity domains, the time constant is shorter and the VO₂ slow component less pronounced in running compared with cycling (Hill et al., 2003). This different profile suggests that VO₂ kinetics may be influenced not only by the central and peripheral structural/ metabolic attributes, but also by the muscle contraction regimen and the ensuing muscle fibre recruitment profile. Notwithstanding the above, two other modes of exercise that have been achieving prominent places within VO₂ kinetics research are swimming and rowing. In fact, recent research has shown that swimming is characterized by a slower VO₂ response compared with other cyclic sports (Sousa et al., 2015), suggesting that the horizontal body position adopted could also be responsible for important differences found in the VO₂ kinetics. Therefore, the characterization of each mode of exercise modality's physiological profile may convey valuable information relating to its specific performance enhancement. The purpose of this presentation is to provide an analysis of the principal VO₂ kinetics differences between exercise modes both during exercise and subsequent recovery. Invited symposia**IS-BN01 TECHNOLOGY AND MODELLING IN GAME SPORTS****THE FUTURE OF WEARABLE TECHNOLOGY FOR GAME ANALYSIS**

ABT, G.

The University of Hull

Although 'wearable' technology has been around for decades (Polar Innovations, n.d.), only recently has the combination of adequate battery power, pervasive wireless networks, and miniaturisation of electronic components, allowed wearable technology to reach mainstream use. The current poster-child of wearable technology for game analysis is the Global Positioning System (GPS). GPS provides coaches and sport scientists with information on player location and its derivatives - speed and direction. Current GPS systems also include heart rate monitoring, together with triaxial accelerometers and gyroscopes, which are increasingly being used to measure rapid

changes in direction and speed (Aughey, 2011). Despite wide adoption of GPS, we have only just begun to explore the potential of wearable technology for game analysis. For example, we now have the capability to measure a wider range of physiological data, including temperature, hydration status, heart rate variability, and even blood lactate. These measures can be obtained through new methods of data acquisition such as flexible skin-mounted sensors (MC10, n.d.), electronic circuits sewn into fabric (OMsignal, n.d.), electromyography (Leo, n.d.), or near-infrared spectroscopy (BSX Insight, n.d.). All of this data is available in real-time and connected to the cloud for storage and sharing via wireless networks. Vast amounts of data collected from this array of wearable technology will increasingly allow the use of multivariate approaches to analysis as used in machine learning and data mining. However, it will be the fusion of these data (Weaving et al., 2014; Liu et al., 2012) that will provide unique insights into not only the stress placed on players during training and competition, but also the interactions between the physical, technical, and tactical aspects of a game. PRACTICAL IMPACT OF MODERN PERFORMANCE ANALYSIS IN FOOTBALL

LAMES, M.

Faculty of Sports and Health Science

The advent of new technologies and the interest of media in enhanced reports have advanced football to the most analysed sports in Europe. This development was accompanied by the hope for improvements in football practice as well as competition analysis. Meanwhile, some critical opinions gave rise to a 'practical impact debate' with controversial positions. A basic reason for the failure of performance analysis research to provide hints for practical improvement is the applied research strategy. There are fundamental differences between the applied basic research and applied research, that would in fact be needed to generate practical impact. Some basic requirements for a practice oriented research program in performance analysis are:

- Adaptation of qualitative methods to arrive at sound interpretations of player behaviour.
- Integration of background information (tactics, preparation, opponent, situation) for assessing the quality of actions.
- Interpretation of results from basic research only as background information for practical analyses.
- Development of a new generation of game analyses that make use of the new data available and aim at assessing constructs on a higher tactical or physiological level oriented at the information needs of practice.
- Investigation of football from the aspect of emergency and contingency for a better understanding of its nature.

GAME ANALYSIS IN THE ERA OF BIG DATA: A SYNTHESIS APPROACH

DUARTE, R.

Faculdade de Motricidade Humana, Universidade de Lisboa

In the last 15 years, we entered in a period of accelerated access to large amount of data (Barris & Button, 2008). Today, tracked positional data and multiple-event notation systems are undoubtedly available at professional club setting. Performance analysis, like most scientific disciplines, lives in the era of 'big data' (Howe et al., 2008). As such, one important consequence is that performance analysts are struggling with large amount of data. This implies a re-definition of the more appropriate methods and tools to use and, consequently, the way analysts are educated to deal with them (Donovan, 2008). Thus, despite the need to have sophisticated technologies compiling all the statistical information from match performance, there is also a need to develop 'synthetic' methods and tools to enhance the usability of such 'big data' (e.g., Lames & McGarry, 2007). According to the 2011 McKinsey Global Institute report (Manyika et al., 2011), this need is particularly important when practitioners are interested to extract meaningful information from large amount of data sets and not only on how to store it in long-term. Here, we review and propose some modelling and visualization tools allowing to objectively quantifying the individual, group and team performance in game sports. The modelling tools that will be under our scope are social networks analysis, cluster phase analysis and dominant region diagrams. Also, we will introduce the multiplexity concept once team players forge-and-broke different kind of networked relationships (e.g., passing relations, switching positioning relations, positioning stability relations, etc., Hanneman & Riddle, 2005). Invited symposia

IS-BN02 BIOMECHANICAL FUNDAMENTALS, ADAPTATIONS AND IMPAIRMENTS OF LOWER LIMB FUNCTION

MUSCLE AND TENDON MECHANICS FOR EFFICIENT MOVEMENT AND CONTROL

LICHTWARK, G.

The University of Queensland

Muscles are responsible for generating the mechanical work that is required for humans and other animals to move. However, one of the key factors that influences muscle performance is not actually associated with the contractile tissue itself, but instead in the elastic connective tissues that transmit force from the muscle to the skeleton and act to absorb and generate mechanical power for efficient locomotion. I will discuss the factors that contribute to energy consumption in muscle and describe how tendon compliance is tuned to

enhance efficiency in walking and running in a range of different muscles in the lower limb, even in muscles that do not support body weight (e.g. tibialis anterior, tibialis posterior). I will also provide evidence of the protective effect that tendons can have in limiting muscle strain during eccentric muscle actions. Innovative methods for measuring and understanding muscle-tendon interaction during dynamic movements, including musculoskeletal modelling and ultrasound image processing, will be described with insight into how they might be used to assess muscle and tendon function. Finally, I will discuss the implications for changing tendon compliance and how this influences muscle force development, energetic cost of performing contractions and the subsequent control of movement.

MUSCLE AND TENDON ADAPTATIONS TO TRAINING: A FUNCTIONAL PERSPECTIVE

SEYNNES, O.

Norwegian School of Sport Sciences

The effectiveness and efficiency of ambulatory activities depends on the interaction between the architecture of lower limb muscles and the viscoelastic properties of connective tissue/ tendons to which they are connected. Training studies indicate that both parameters are altered following a period of exercise (1, 2), although the mechanisms underpinning some of these adaptations remain elusive. An increase in pennation angle is often associated with muscle hypertrophy following resistance training, and is assimilated to the necessary accommodation of additional parallel sarcomeres. However, direct evidence of this assumption is currently missing. Furthermore, animal studies have shown that muscle fibre plasticity can occur lengthwise, via the addition of serial sarcomeres. Yet, reports of exercise-induced changes in fascicle length are conflicting, with some studies showing fascicular lengthening under certain training modalities (e.g. eccentric contractions), while others did not. Tendons display metabolic and structural adaptations following resistive training. In most cases, these changes are accompanied by an increase in stiffness and/or Young's modulus. Scarce data also indicate a decrease in hysteresis. However, the time course and relative contribution of material and structural changes to mechanical behaviour differ considerably between studies, and information is lacking regarding adaptive patterns of tendinous tissue. In this presentation, I will review some aspects of training-induced changes in muscle and tendon and discuss their functional significance. References: 1. IMPAIRED LOWER LIMB FUNCTION: WHAT'S WRONG IN ATHLETES WITH CHRONIC ANKLE INSTABILITY?

GEHRING, D.

University of Freiburg

A main feature of human locomotion is to protect the musculoskeletal system against harmful overloading. If those neuromuscular and structural/anatomical protective mechanisms fail, injuries are very likely. One of the most frequent examples of sports injuries is an ankle sprain, which leads very often to the development of chronic ankle instability (CAI). It is thought that the concept of CAI encompasses both, mechanical ankle instability, i.e., an impaired structural protection, as well as an impaired function of the neuromuscular system to control the ankle during daily and sportive activities. I will discuss that CAI and especially its neuromuscular impairments are not completely understood yet. Results are diverse, for instance indicating an impaired postural stability and invertor strength without differences in ankle range of motion or muscle reflex latencies compared to healthy controls. Hence, this talk will focus on most recent research approaches, which aim to evaluate ankle joint control in functional dynamic situations trying to assess both feedforward and feedback control mechanisms. Therefore, complex game-like situations are biomechanically analysed. In addition, ankle sprain mechanisms are imitated to assess features of neuromuscular joint control in individuals with CAI and its sub-entities. This talk will indicate how these approaches may help us to better understand the problem of CAI.

Invited symposia**IS-SH01 THE FAN CAN: THE MEDIA AND FOOTBALL SUPPORTER COMMUNITIES AS ENABLERS OF MULTICULTURAL ENVIRONMENTS****FEMALE FANS OF MEN'S FOOTBALL - SOCIALISATION, MOTIVATION AND CIRCUMSTANCES OF LIFE**

PFISTER, G.

University of Copenhagen

Football is an invention by men for men, and today, the majority of players and fans are men. There is an abundance of literature on football and fandom; however, gender is mostly not an issue in these publications. Research about female football supporters and fans is very limited. Based on gender concepts, socialization theories as well as on approaches to circumstances of life, this contribution addresses women and their (lack of) interest in men's football. The main questions refer to the numbers of female supporters and their patterns of football consumption. The sources of information are user data of mass media, results of a survey about football fans in a number of European countries (conducted by members of the FREE project) and the results of an interview study with female fans. A specific focus of this article is on the minority of female supporters who attend football games. How do they become fans, adapt to a 'man's world' and integrate football in their everyday lives? What are their roles in the 'male environment' of the game and its fans? The results of a survey and the statements of interviewees revealed that female fans have to cope with a measure of sexism, and that they often adopt the men's perspectives in order to be accepted as 'authentic fans'. Other women reacted on men's domination in the football stadium by founding women only fan groups that seem to allow them to find their own way to be women and fans.

SOCIAL RESILIENCE: SPORT AS A PLACE FOR AUTONOMOUS ORGANIZING AND SELF-LEARNING

KROVEL, R.

Oslo and Akershus University College, Norway

Much recent social research has tried to understand social and community resilience. Community resilience will here be broadly defined as the ability of a community to respond to crisis by drawing on local resources of all types to help themselves. Autonomous organizing and self-learning seem to be crucial aspects of resilient communities. This paper will reflect on the role of sport in producing resilient communities in a time of mass migration, mass tourism, hyper consumption and global flows of information and images. It summarizes four investigations into fan activism and fan re-construction of imagined communities in Norway and what it means to belong to these communities. It will also try to interpret new forms of organizing and self-leaning in comparison with earlier forms described in the literature on Norwegian sports and social organization. The four cases highlight important aspects of the collective social agency these fans have in times of mass migration, mass tourism, global flows of images and information and hyper consumption. The cases demonstrate that communities of fans can become collective agents for social change and social resilience through autonomous organization and self-learning. Nonetheless, a few paradoxes need to be explored further. First, Norwegian membership of fan organizations for clubs such as Liverpool and Manchester by far exceeds membership of local supporter organizations at home. The meanings of this will be explored by drawing on theories and concepts such as "De-territorialization" (Deleuze and Guattari), "Cloakroom identities" (Bauman) and the fan as "Flâneur" (Giulianotti). Another concern is related to the interplay between online communication and social interaction with other members of the local community. Based on these cases, it seems as face to face interaction and communication plays a key role when social identities and imagined communities are being transformed to include for example immigrants, Muslims and gay men as valued members. When online communication is detached from other forms of social interaction and communication, identity politics have been observed to spiral into extreme forms of identity based politics, such as racism and homophobia. A third paradox is related to the imbalance between membership in fan clubs and the clubs themselves. Norwegian historians focus on clubs and organizations not only as sites that produce identities, feelings of belonging, imagined communities etc., but also as spaces of learning. An organization is a place where the members teach themselves how to organize, cooperate and to participate as potentially equal members with shared rights and responsibilities. Seen from the perspective of community resilience, these new forms of global fandom faces local communities with a number of challenges regarding certain aspects of autonomous organizing and self-learning. These challenges will be discussed further in the paper.

SUPPORTER CULTURE – FOR WHOM? WOMEN'S PERCEPTION OF FOOTBALL ARENA CULTURE IN SWEDEN

RADMANN, A.

Malmö University

Football supporter culture has been studied and analysed since the 1960s from historical, economic, sociological, cultural and psychological perspectives. Important questions within the field have been who the football supporters are, what influences them, how they can be understood, whether they are violent or well behaved, and what kind of identities are developed within the football supporter culture on a local, regional, national or international level. Most studies on football supporters have focused on men and on men's supporter culture and research on female fandom is lacking. This study has a different focus, as female supporters in a Swedish context will be studied. The aim is to map out and analyse female supporters' views of their situation in Swedish football supporter culture. Of special interest is the question of whether female supporters express the same ideas on gender specific codes within the supporter culture as the male supporters. Method: Interviews with 18 female supporters from Swedish clubs are analysed. The interviews last between one to two hours and are recorded and transcribed. Life stories from four females presented in two different books on supporter culture are used too. The theoretical framework is based on Erving Goffman's dramaturgical perspective, and Judith Butler's notion of performative gender. Results: In the interviews and the life stories of the female supporters, three themes emerge in women's description of their football fandom: restrictions, respect and freedom.

Invited symposia**IS-SH02 INTERCULTURALITY IN SPORTS – DIFFERENT APPROACHES, EFFECTS AND DILEMMAS****EVALUATING AN INTERCULTURAL EDUCATION PROGRAM FOR PHYSICAL EDUCATION**

GIESS-STUEBER, P., GRIMMINGER, E., MÖHWALD, A.

University of Freiburg, TU Dortmund University

Experiences of strangeness become inevitable in socially and ethnically differentiated societies. Based on a sociological, social constructivist and socio-psychological theoretical framework didactical guidelines for physical education were developed with the aim to promote the handling of strangeness in a constructive way (Gieß-Stüber, 2008). This didactical concept was implemented in two different settings to evaluate on the one hand the impact of the concept on relevant socio-cognitive structures for the handling of strangeness, and on the other hand to evaluate how the concept is accepted by target groups, i.e. students. The first evaluation aim was pursued by a quasi-experimental eight weeks intervention study in physical education classes with N=121 students (mean age 11.70 years; SD=.59). Questionnaires evaluated the development of the socio-cognitive structures; video records focused the intervention process. The second evaluation aim was realized in a local sport for development project: a mixed-method study in football groups for girls in residential areas with a dominant rate of families at social risk and with migration background. The integration of all empirical findings elucidate that the didactical concept of intercultural education in PE must be reformulated and focused on specific target groups. Gieß-Stüber, P. (2008). Reflexive interculturality and interaction with strangeness in sport and through play. P. Gieß-Stüber & D. Blecking (eds.), Sport – Integration – Europe. Widening Horizons of Intercultural Education (pp. 228-242). Baltmannsweiler: Schneider.

ASSESSING INTERCULTURAL PROCESSES AND OUTCOMES IN THE SPORT FOR DEVELOPMENT AND PEACE FIELD

RATO BARRIO, M.

Universidad Politécnica de Madrid

The promotion of intercultural relations has become a frequent objective in the field of Sport for Development and Peace (SDP); however, we lack coherent theoretical fundaments and specific indicators for measuring intercultural processes and outcomes in the Global South, and as a consequence there is little evidence about the effects of sport in this context. Therefore, a theoretical framework will be presented, which was operationalized and tested in a sport programme (PIDE) in the post-war context of Guatemala with data from 100 participants in four intervention groups and a control group with 557 youths. The results of the PIDE show positive effects in the 4 mentioned intervention groups regarding the affective, cognitive and behavioural elements of tolerance towards diversity and the categories defined for the three phases of the intercultural process (decentring, comprehension and negotiation). Methodological issues and challenges of this programme as well as of other similar SDP initiatives are critically discussed. Finally theoretical and practical recommendations are drawn for further SDP initiatives and the assessment of intercultural processes and outcomes.

THE INTERCULTURAL PERSPECTIVE OF PHYSICAL EDUCATION: GOALS, DIDACTIC STRATEGIES, AND SOCIAL OUTCOMES IN THE ELEMENTARY SCHOOL

DERRI, V., KELLIS, I.

Democritus University of Thrace

The rapid and diverse changes that our world is experiencing challenge the traditional societal and educational policies. Education should be directed to promote understanding, tolerance and positive relations for all students, through certain policies, if it is to make a significant contribution to a peaceful and fruitful society. To this end, Intercultural Education (IE) is considered a key premise. The core values of IE, such as respect and responsibility not only are prerequisites for the implementation of Physical Education (PE) but also form its emotional/social goals which are expected to be achieved through movement activities. Therefore, the current presentation attempts to show a) the relation between IE and PE goals and didactic strategies; b) the intercultural PE initiatives in Greece; c) the impact of an Intercultural PE program on elementary school students' social and emotional skill learning. Results are discussed in terms of the existence of similarities between IE and PE, and the positive effects of the IPE intervention on student social and emotional development.

Invited symposia

IS-EX01 ECSS - ACSM EXCHANGE SYMPOSIUM: Preparing for the Olympics - an European and American viewpoint

SPORT SCIENCE AND INNOVATION AT THE NETHERLANDS OLYMPIC COMMITTEE

MAASE, K.

*NOC*NSF/Netherlands Olympic Committee*

Former elite distance runner Kamiel Maase is performance manager sport science & innovation at the Netherlands Olympic Committee (NOC*NSF). In this role, he contributes to bridging the well-known gap between science and sports on a daily basis. A solid foundation has been built over the past seven years. His work involves, of course, interaction with both coaches and academics. But he interacts with businesses as well. His network has expanded and numerous projects – some highly academic, others very practical – have been carried out. With the 2016 Rio Olympics approaching, coaches and athletes demand evidence-based, practical advice as well as concrete innovations supporting performance. Kamiel explains how NOC*NSF approaches applied sport science and innovation, and will present specific examples of projects, both long-term and short-term, on the Road to Rio. The presentation is part of the ACSM-ECSS exchange symposium. Randy Wilber (US Olympic Committee) will represent the United States. The presentations will allow comparisons between the US and European approach to be made. The audience is invited to actively contribute to the discussion and ask questions.

USE OF SPORT SCIENCE BY OLYMPIC ATHLETES FOR MEDAL PERFORMANCE IN RIO 2016

WILBER, R.

United States Olympic Committee

Team USA has produced relatively strong performance results in the Olympic Games since the inception of the modern Olympics in 1896. Team USA is comprised of several national governing bodies (NGBs), which provide both the administrative structure and performance-support structure for elite athletes and coaches within that particular NGB, or sport. USA Swimming and USA Track & Field are historically the two most successful NGBs in Olympic sport for Team USA. These two NGBs alone have consistently won approximately 60 percent of the total medals won by Team USA at any given Olympic Games, and this trend is expected to continue at the RIO 2016 Olympics. The overall strategy of USA Swimming and USA Track & Field in preparation for RIO 2016 is to "defend" medals in traditionally successful events, and to "go on offense" in events where returning Team USA athletes placed 4th through 8th in LONDON 2012, or in events that are relatively new (e.g., 10km swimming). This presentation will focus on select Olympic athletes from USA Swimming and USA Track & Field, and their implementation of various components of sport science in preparation for RIO 2016. Highlighted within this presentation will be examples of specific "Olympic performance initiatives" utilized over the past four years with medal-potential athletes from USA Swimming and USA Track & Field.

OP-PM13 Muscle Strength

BLOOD FLOW RESTRICTION RESISTANCE EXERCISE PERFORMED SUB-MAXIMALLY OR UNTIL VOLUNTARY FAILURE INDUCES SIMILAR INCREASES IN MUSCLE SIZE AND STRENGTH

SUNDNES, J., BJØRNSEN, T., BRANKOVIC, R., STÅLESEN, H., BERNTSEN, S., PAULSEN, G., WERNBOM, M., RAASTAD, T.

University of Agder

Introduction Blood flow restriction resistance exercise (BFRRE) using loads as low as 20% of 1 repetition maximum (1RM) can induce rapid increases in muscle size and strength (Nielsen et al., 2012). No study has investigated the importance of conducting BFRRE to voluntary failure; therefore the present study aimed to compare the effect of a failure protocol (FA) vs. a submaximal protocol (SU) on changes in muscle size and strength during BFRRE. Methods Seventeen untrained men (18-45yrs, participating in < 2 leg-strength-sessions per week the last six months), had their legs randomized to one of two BFRRE protocols: one leg performed four sets to voluntary failure, whereas the submaximal leg aimed for four sets with 30-, 15-, 15- and 15 repetitions. The intervention consisted of two periods including seven BFRRE sessions within five days (separated with 10 days rest) using unilateral knee extension at 20% of 1RM (30 s rest between sets). The pressure cuff stayed on during all four sets and was inflated to 100 mmHg (13.5 cm pressure zone). Muscle size was measured as muscle-thickness (m. rectus femoris, m. vastus lateralis and m. vastus intermedius) and cross-sectional area (CSA) (m. rectus femoris) with ultrasound imaging. Ultrasound and 1RM (knee extension machine), measurements were conducted before, during and after the intervention; seventeen days after last BFRRE session for ultrasound and twenty-four days after for 1RM. Results Muscle thickness of m. rectus femoris increased significantly in both FA ($10.5 \pm 5.8\%$; $p < 0.001$) and SU ($10.0 \pm 5.7\%$; $p < 0.001$) compared to baseline. FA increased the muscle thickness of m. vastus lateralis ($5.9 \pm 4.5\%$; $p < 0.001$), while only a tendency was observed in the SU group ($6.6 \pm 4.8\%$; $p = 0.07$). No significant increases in m.vastus intermedius were found in FA and SU. CSA of m. rectus femoris increased significantly in both groups compared to baseline (FA: $7.9 \pm 7.6\%$; $p < 0.001$ and SU: $9.1 \pm 10.8\%$; $p = 0.003$). We did not observe any group differences in the changes of muscle thickness or CSA. Maximal strength (1 RM) increased significantly in both groups (FA: $9 \pm 8\%$; $p < 0.001$ and SU: $11 \pm 7\%$; $p < 0.001$) compared to baseline. We found no group differences, except a tendency (FA: $-5 \pm 8\%$ and SU: $-1 \pm 8\%$, $P = 0.07$) within the 10 days of rest. Participants described SU as less demanding and more feasible compared to FA. Discussion We did not observe any difference between the two BFRRE protocols, considering improvements in muscle size or maximal strength; both groups had a similar improvement in muscle size and strength compared to baseline. Importantly, the participants described SU as less demanding relative to FA. Therefore, it may not be necessary to conduct BFRRE to voluntary failure in order to achieve optimal gains in muscle size and muscle strength. THE EFFECT OF HEAVY AND LIGHT RESISTANCE TRAINING ON SKELETAL MUSCLE STRENGTH AND FUNCTION IN ELDERLY INDIVIDUALS

BECHSHØFT, R.L., HØJFELDT, G.W., REITELSEDER, S., KJÆR, M., HOLM, L.

Bispebjerg Hospital

Background: Skeletal muscle mass decreases with up to 1-2% per year from around the age of 50 and the muscle strength even more. This bodily deterioration often leads to functional impairment and dependency or home care. The aim of this study was to investigate the impact of intensity and settings of resistance exercise training on the efficacy to counteract this age-related decline in elderly subjects. Methods: A total of 45 subjects was randomized to 12 weeks of center-based progressive heavy resistance training (RT) (HRTW), home based light rubber band RT (LITW) or no training (WHEY) of the legs with n=15 in each group. All subjects consumed 20g of whey protein twice daily: one at morning and one at lunch. Before and after intervention knee extension peak torque and power, 30s chair-stand, 400m gait speed, MRI-based quadriceps muscle cross sectional area (CSA) and body-composition (DXA) were assessed. Current data are on 32 subjects. Final tests are scheduled for March 2016. Results: Two-way RM ANOVAs were applied with Holm-Sidak post-hoc test when interaction was detected. Mean age of completed subjects was 70 ± 4 (SD) years. Intention-to-treat analysis revealed that HRTW (n=11) increased peak isokinetic and isometric strength 12.7 ± 13.6 (SEM) Nm (8%) and 19.7 ± 15.6 Nm (11%), respectively ($P < 0.05$). LITW (n=12) and WHEY (n=9) did not change. There was a time-effect on leg fat free mass ($P < 0.05$) with an increase of 369 ± 120 (SEM) g. Thigh power, gait speed and 30s chair-stand was unchanged. Quadriceps CSA and compliance have not been analyzed at time of submission of this abstract. Conclusion: Twelve weeks of RT with heavy but not light loads increased strength but not function in elderly individuals above 65 years. Heavy-loading RT is superior to light-loading RT and can be implemented if feasible.

THE EFFECT OF NATIVE WHEY- VERSUS MILK-PROTEIN SUPPLEMENTATION ON MUSCLE SIGNALLING AND HYPER-TROPHY DURING STRENGTH TRAINING IN ELDERLY

HAMARSLAND, H., SEEBERG, F., JOHANSEN, M., RAASTAD, T.

Norwegian School of Sport Sciences

Introduction Reduced muscle mass and strength with increasing age is a challenge to daily function in many elderly. Resistance exercise and intake of high quality protein has the potential to stimulate muscle protein synthesis (MPS) and thereby counteract the muscle loss. The increased MPS is driven by an increased activity in anabolic signalling proteins (I). In addition to strength training, the amino acid leucine is suggested as a trigger of the signalling networks driving MPS (2). AIM: to investigate if a native whey supplement, known to rapidly increase blood leucine concentrations, enhances anabolic signalling more than milk, and whether this translates into increased hypertrophy and strength during an 11-week strength-training program in elderly men and women. Methods Thirty elderly participants ($\sigma=18$, $\varphi=12$) with a mean age of 74 years were randomized into two groups, receiving 20 g of protein twice per day either as native whey or 1% milk. Both groups performed heavy load strength training three times per week for 11 weeks. Changes in lean mass, m. vastus lateralis thickness and strength, were measured by DXA, ultrasound and 1RM leg press, respectively. Biopsies were collected from m. vastus lateralis in a subgroup of 21 participants, before and 2 h after the first and last workout, to look at acute responses (p70S6K, 4E-BP1 and eEF-2) and training adaptations (muscle fibre area). Results Lean mass (milk: $5.0 \pm 2.6\%$, native whey: $3.8 \pm 2.5\%$), m. vastus lateralis thickness (milk: $7.2 \pm 5.7\%$, native whey: $6.1 \pm 4.7\%$), muscle fibre area (milk: $15 \pm 26\%$, native whey: $13 \pm 21\%$) and 1RM in leg press (milk:

29±14%, native whey: 36±16%) increased significantly in both groups with no differences between groups. The ratio of phosphorylated to total p70S6K increased significantly in both groups at all time points and was greater in the Native Whey group compared to the milk group after the training intervention (21-fold vs. 9-fold). There were no significant changes in 4E-BP1 or eEF-2 phosphorylation. Discussion The strength training intervention was effective in increasing muscle mass and strength in the elderly participants, but there were no differences between groups. In the untrained state supplementing with native whey and milk produced the same activation of p70S6K. However, in the trained state native whey produced a greater activation of p70S6K than milk, indicating an adaptive response. Activation of p70S6K was not correlated with gains in muscle mass or strength during the training intervention. References 1. D. L. Mayhew et al., *J. Appl. Physiol.* 107, 1655–1662 (2009). 2. J. E. THE EFFECT OF GYMNASTIC TRAINING ON MUSCLE STRENGTH AND ACTIVATION DURING ISOMETRIC ELBOW AND SHOULDER FLEXION/EXTENSION

MIESZKOWSKI, J.1, KOCHANOWICZ, A.2, NIESPODZIŃSKI, B.1, MISHCHENKO, V.2, MOSKA, W.2

1: Kazimierz Wielki University (Bydgoszcz, Poland), 2: Gdańsk University of Physical Education and Sport (Gdańsk, Poland)

Introduction The aim of the study was to demonstrate the differences between non-athletes and gymnasts at the pre- and post-pubertal age in the development of the peak torque and ensuing flexion/extension ratios at the elbow and the glenohumeral joints well as an to assess the relevance for the above activities of the co-existing co-activation of selected muscles. Methods The study involved 18 gymnasts and non-athletes aged 8-9 years as well as 12 gymnasts and 16 non-athletes aged 18-25 years. Measurements of the isometric peak torque (PKTQ) have been taken with a use of a dynamometer Biomed System 4 for flexion and extension at the elbow and the glenohumeral joints. To determine the neurophysiological characteristics of the strength capabilities the method of surface electromyography was applied with a use of the Noraxon's TeleMyo DTS in order to calculate the co-activation index. Results In the group of older gymnasts the PKTQ ratio of the arm flexors to extensors was the lowest (0.72) and significantly differed from the other tested groups. This result was influenced by 30% higher PKTQ values ($p < 0.01$) of the arm extensors and their activity in flexion lower by 18% ($p < 0.05$). Discussion Apart from proving the effects of long-term gymnastic training, the results give information about the imbalance between the agonist and the antagonist of the arm, which can predispose to more frequent injuries, as emphasized by Ruivo et al. (2012), Cools et al. (2005), who studied professional athletes from other sports disciplines. Interesting are also results on the elbow joint among gymnasts in whom closer proportions the extensors strength to flexors was primarily associated with an increase in the extensors strength. Non-training persons, in turn, at the background of ontogenetic development, headed towards the advantage of the strength of elbow flexors. This problem is undoubtedly worth greater attention in future research. Conclusion A disproportionately greater development of strength capabilities of extensor muscles in relation to arm flexors among experienced gymnasts can provide valuable information for physiotherapists and coaches on individuation of athletes' special preparation – essential in teaching many complex gymnastic exercises, as well as in the prevention of injuries. THE EFFECT OF SPINAL MOBILIZATION ON LOWER LIMB STRENGTH

LO, C.N., LAM, P.Y., LAU, M.Y., SIU, W.L., YU, K.M., YUEN, T.S., NG, K.F.

The Hong Kong Polytechnic University

Background: There is limited evidence regarding the effects of spinal mobilization on the reduction of extremity muscle inhibition in asymptomatic subjects. In addition, the potential of the possible strength gain by spinal mobilization to be reflected in functional performance has yet to be investigated. Purpose: The purpose of our study was to investigate whether passive lumbar spine mobilization on L2/3 can improve hip flexion strength and performance in single-leg triple hop (SLTH) test in asymptomatic young adults. Methods: Our study adopted a pretest-posttest sham group design. Twenty-four participants (M=12; F=12), aged from 19 to 26, being positive in hip flexor 'break' test, which indicated hip muscle weakness could be caused by neuromuscular inhibition, were recruited. They were randomly allocated into treatment group (passive lumbar rotation at L2/3) or sham group (passive hip joint mobilization). Isometric hip flexor torque (Nm) and SLTH distance (cm) were measured before and after intervention. Results: After intervention, the treatment group illustrated a significantly higher (+3.41% ± 5.44%) ($p=0.02$) positive percentage change in torque than the sham group (-2.36% ± 5.81%). Both the treatment and the sham groups showed significant increase in SLTH distance ($p=0.040$ and 0.044 respectively). Conclusions: The study results showed a potential effect of passive lumbar rotational mobilization on decreasing hip flexor inhibition. However, improvement in SLTH performance could neither be differentiated as the effect from treatment, nor placebo or learning effects. Implications: Our study provided an insight that lumbar rotational mobilization could be a possible way to manage hip flexor inhibition, thus to regain/ increase hip muscle strength. Hip flexor inhibition can be presented without back pain. Therapists are therefore advised to include the screening of hip flexor inhibition during assessment when patients encountering lower limb conditions even without back pain. Funding acknowledgements: The authors reported no funding or conflicts of interest in this study.

EFFECTS OF FOUR WEEKS OF UNILATERAL ISOMETRIC LOW INTENSITY STRENGTH TRAINING, WITH AND WITHOUT BLOOD FLOW RESTRICTION, ON MVC, CROSS SECTIONAL AREA, THE V-WAVE AND H-REFLEX OF THE SOLEUS MUSCLE

MÁRQUEZ, G., COLOMER-POVEDA, D., VERA-IBÁÑEZ, A., VIÑUELA-GARCÍA, M., ROMERO-ARENAS, S.

Catholic University of Murcia

Introduction. Low Intensity Blood Flow Restriction Training has been proven to be an effective method to increase strength together with muscle mass (Lonneke et al., 2011; Takarada et al., 2000). However, it remains unknown if this type of training promotes similar neural adaptations to those find after traditional strength training, such as increased volitional wave (V-wave) and Hoffman reflex (H-reflex) (Aaggard et al., 2001). Therefore, the aim of the present study was to test the effects of four weeks of unilateral isometric low intensity strength training, with and without blood flow restriction, on maximal voluntary contraction (MVC), cross sectional area, the volitional wave and the Hoffman reflex of the soleus muscle. Methods. Twenty two healthy males were voluntary involved in this study. Subjects were randomly distributed in three different groups, a control group (CON; n=8), a low intensity blood flow restriction resistance training (LI_BFRT; n=7) and a low intensity training resistance training (LI_RT; n=7) groups. Both experimental groups completed four sets of unilateral isometric low intensity (25% of MVC) resistance training three times a week during four weeks. The load, repetitions and sets were

exactly the same in both groups. However, an inflatable cuff was applied to occlude blood flow on the dominant leg of the LI_BFRT subjects during each training session. Results. The results showed that MVC increased 33% ($p<0.001$) and 22% ($p<0.01$) in the training leg of both LI_BFRT and LI_RT groups, respectively. The soleus thickness increased 9.5% ($p<0.001$) and 6.5% ($p<0.01$) in the training leg of both LI_BFRT and LI_RT groups, respectively. However, neither MVC nor thickness changed in any of the legs tested in the CON group. Moreover, V-wave and H-reflex remained unchanged in all the groups studied when tested in both trained or control leg. Discussion and conclusion. Our data are in accordance with previous studies showing that EMG or voluntary activation does not change when a LI_RT, with or without blood flow restriction, is applied (Kubo et al., 2006; Moore et al., 2004). It seems that strength gains are related with changes occurred in the cross sectional area, at least, when the training period is no longer than four weeks. It is interesting to note that to the best of our knowledge this is the first study confirming that these types of trainings protocols do not elicit adaptations in the neural drive or motoneuronal function. OP-PM12 Sports Medicine: Injury - Tendons

THE CHALLENGE OF DIAGNOSING PLANTARIS TENDON INVOLVEMENT IN MIDPORTION ACHILLES TENDINOPATHY – A STUDY USING US+CD, UTC AND CLINICAL ASSESSMENT

SPANG, C.1, MASCI, L.2, VAN SCHIE, H.3,4, ALFREDSON, H.2,4,5

1: Anatomy Section, Umeå University (Sweden); 2: Pure Sports Medicine Clinic (London, UK); 3: UTC imaging (Stein, Netherlands); 4: UCLH (London, UK); 5: Sports Medicine Unit, Umeå University

Introduction Chronic painful midportion Achilles tendinopathy is a troublesome condition that frequently affects professional and recreational athletes in running and jumping disciplines. Recently, it has been shown that in patients who did not respond to common treatments such as eccentric training, a thickened plantaris tendon being positioned close to and seemingly compressing onto the medial side of the Achilles tendon ("plantaris tendon involvement") was often found (Alfredson, 2011). Surgical removal of the plantaris tendon has resulted in promising outcome. However, little is known about how to diagnose this condition. The aim of this study was therefore to evaluate whether imaging tools and clinical assessment can predict plantaris tendon involvement. Methods Twenty-three tendons in 18 patients (14 men, mean age: 37 years and 4 women: 44 years) with midportion Achilles tendinopathy were surgically treated with plantaris tendon removal and additional scraping procedure (Alfredson, 2011). Clinical assessment, Ultrasound + Colour Doppler (US+CD) examination and Ultrasound Tissue Characterisation (UTC) were performed and compared with the macroscopic findings during surgery. Results At surgery, all 23 cases had a plantaris tendon positioned close to the medial side of the Achilles tendon. Clinical assessment revealed localised medial activity-related pain in 20/23 tendons and focal medial tendon tenderness in 20/23 tendons. For US+CD, 20/23 tendons had a tendon-like structure interpreted to be the plantaris tendon and 23/23 had localised high blood flow in close relation to the medial side of the Achilles. For UTC, 23/23 tendons had disorganized (type 3 and 4) echopixels located in the medial area of the Achilles tendon indicating possible plantaris tendon involvement. Discussion In conclusion, in patients with midportion Achilles tendinopathy, medial tenderness and activity related medial pain might indicate plantaris tendon involvement. US+CD can directly visualise the plantaris tendon in a high proportion of the patients, and UTC seems to have potential to indirectly detect a plantaris tendon located close to the medial Achilles tendon. The results of this study provide important information on how to diagnose a plantaris-associated Achilles tendinopathy and can thus help clinicians and therapists to adapt the rehabilitation program. THE IMPORTANCE OF THE TNF SYSTEM IN OVERUSED/DAMAGED MUSCLE AND TENDON

RENSTROEM, L., SPANG, C., ALFREDSON, H., FORSGREN, S.

Anatomy

Introduction: TNF alpha is known to be involved in various aspects of damage and inflammation, as well as restitution, in different tissues. There is, however, little knowledge of the importance of TNF alpha in overused/damaged muscle and tendon. This is a drawback as TNF alpha may have many important functions in conditions with reorganization and damage and as pain in response to damage and overuse for muscle and tendon are troublesome situations. Materials & Methods: Muscle tissue from overused rabbit muscle was examined. The rabbits had been exposed to overuse concerning their soleus muscle via the use of an experimental procedure that has been developed in the laboratory and which has been used for evaluation of the importance of other signal substances than TNF alpha. Material from human tissue was also examined; material obtained from operations for Achilles tendinopathy (tendinosis). The material corresponded to tissues from the plantaris tendon, which has been found to be highly influenced when being located very close to the Achilles tendon in this situation. The material also corresponded to tissue from the peritendinous region, a region known to have an importance in the tendinosis situation. Immunofluorescence and antibodies towards TNF alpha and the TNF receptors I and II (TNFRI and TNFRII) were applied. Results: The TNF-alpha is expressed in white blood cells in the connective tissue, as in some extent in the fibroblasts in overused/damaged rabbit muscle tissue. The TNF receptors are present in white blood cells, fibroblasts, muscle fibres and muscle cell nuclei, blood vessels, neuromuscular junctions and nerve fascicles. In some cell types, TNF receptor expression were present in both healthy and damaged muscle tissue in compare with other cell types where expression extended the more damaged/overused the muscles were. The muscle fibres expressing TNF receptors were either of a degenerating or regenerating stadium. Concerning the human situation it was found that tenocytes in the plantaris tendons exhibited TNF alpha as well as TNF receptor immunoreactivities. Furthermore, the numerous cells occurring in the loose peritendinous tissue frequently exhibited immunoreactions for TNF alpha and TNF receptor. In addition, TNF receptor immunoreactivity was markedly seen for the walls of the blood vessels that were frequently present in tendon tissue and in the loose peritendinous tissue. Discussion: The findings show that the TNF system is likely to play an important role in the processes that occur in a muscle that is markedly overused and in tendon tissue as well as peritendinous tissue in the Achilles tendinosis situation. TNF alpha may via effects on its receptors cause tissue damage by inflammatory and cell death mechanisms as well as regeneration by myogenesis mechanisms.

FUNCTIONAL PERFORMANCE DEFICITS SIX MONTH AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

KRAFFT, F.C.1, STETTER, B.1, STEIN, T.1, ELLERMANN, A.2, FLECHTENMACHER, J.3, EBERLE, C.2, SELL, S.1, POTTHAST, W.2,4

1: *KIT 2: Arcus Clinics, Pforzheim 3: Ortho-Zentrum, Karlsruhe 4: GSU*

Introduction Consequences of an ACL rupture are a loss of function and stability in the knee (Rudolph et al., 2000). Reconstruction and subsequent rehabilitation are common approaches to regain function and stability. However, the rehabilitation process does not assure full knee stability and return to sports on pre-injury sports-level (Lentz et al., 2009). The aim of this study was to evaluate the function of the knee after ACL injury in a multifaceted test battery throughout the rehabilitation process with focus on the leg symmetry index (LSI). This should help to find criteria for a safe return in pre-injury sports and sports-level. Methods 20 patients with unilateral tear of the ACL were tested at T1 six weeks after injury; T2 six weeks, T3 three and T4 six month after reconstruction. A control group was matched in respect to age, body height, mass and the activity level and was tested once. Subjects had to self-evaluate themselves with the Tegner-Activity-Score (TAS) and the Knee Injury and Osteoarthritis Outcome Score (KOOS) at all test sessions. The subjects performed bilateral counter movement jumps, one-leg jumps for distance and isometric force tests in 90° and 110° knee flexion and extension. In the jumps, heights and distances along with take-off and landing impulses were calculated. In the isometric force tests, peak forces, peak rate of force development (RFD) and peak RFD in the first 200 ms of contraction were calculated. Thereof the LSIs were calculated by dividing the results of the injured leg by the result of the uninjured leg in the ACL group and non-dominant divided by the dominant leg in the control group. To determinate differences over the four test sessions one-way ANOVAs with repeated measures were conducted. The results of T4 of the ACL group were compared to the results of the control group with a t-test for independent samples. Results In all analyzed parameters decreases of the LSIs from T1 to T2 ($p < .05$) were found. From T2 to T4 the LSIs increased towards a balanced level. However, the ACL patients, showed in comparison to healthy controls, lower LSIs six month after reconstruction ($p < .05$). Additional, ACL patients do self-evaluate their activity level six month after reconstruction lower than the pre-injury level was ($p < .05$). Discussion The lower LSIs six months after ACL reconstruction and the low self-evaluation leads to the conclusion that a general return to pre-injury sports level six month after reconstruction seems often too early. Therefore the functional status should be evaluated throughout the rehabilitation process to monitor the development of the leg symmetry over time after ACL injury. TIME COURSE OF COSTAMERE PROTEIN CONCENTRATIONS AFTER ROTATOR CUFF TENDON RELEASE IN SHEEP

RUOSS, S.1, MÖHL, C.B.1, WIESER, K.1, BENN, M.C.2, VON RECHENBERG, B.2, MEYER, D.C.1, GERBER, C.1, FLÜCK, M.1

1: *Balgrist University Hospital, University of Zurich (Zurich, Switzerland)*, 2: *VetSuisse Faculty, University of Zurich (Zurich, Switzerland)*

INTRODUCTION Tears of rotator cuff tendons are a frequent cause of shoulder complaints in athletes (Lazarides et al., 2015). If not repaired early, they lead to atrophy and fatty infiltration of the affected muscle. Early treatment with nandrolone mitigates this process in sheep (Gerber et al., 2015). Costamere components were investigated previously in the events of unloading through tendon release (TR) (Klossner et al., 2013) and adipocyte differentiation (Li and Xie, 2007). The aim of the present study was to assess the effects of simulated rotator cuff tendon tear and nandrolone treatment on costamere components in sheep. METHODS The tendon of the m. infraspinatus was surgically released in 18 female Swiss Alpine sheep. The animals were assigned to two groups defining a time course (TR2, age: 16.6 (0.0) months, N = 6; TR16, age: 23.2 (1.2) months, N = 6) and to a third group receiving weekly injections of nandrolone decanoate (TR16+NAN, age: 23.8 (1.2) months, N = 6). Muscle biopsies were collected prior to TR (all groups), and two weeks (TR2) or 16 weeks (TR16, TR16+NAN) after TR. Costamere protein concentrations/total protein were assessed through Western blotting with the contralateral muscle as control. Experiments were performed according to the Swiss law of animal welfare (TSch455) and approved by local authorities. All data are presented as mean (SD). Differences between and within groups were detected with a general linear model with repeated measures and LSD post-hoc test (SPSS, IBM). Statistical significance was defined as $P < 0.05$. RESULTS The concentration of the C-terminal 190kDa proteolytic fragment of talin significantly increased with 16 weeks of TR (2.2 fold, $P < 0.001$), but not with 2 weeks ($P = 0.44$). Full length talin protein concentration did not change. Nandrolone administration prevented the cleavage of talin and the increase of intramuscular fat content. Focal adhesion kinase, gamma- and meta-vinculin protein concentrations remained unaffected. DISCUSSION The differences in talin fragment abundance indicate alterations in costamere turnover, which seem to be part of the nandrolone-mediated pathway that reduces the degeneration of the rotator cuff muscle. Oral presentations**OP-SH10 Psychology: Motivation 1****PREDICTORS OF ANTISOCIAL ATTITUDES AND DOPING INTENTIONS IN SPORT: THE ROLE OF COACH INTERPERSONAL STYLE AND ATHLETES' PSYCHOLOGICAL NEEDS**

NTOUMANIS, N.1, BARKOUKIS, V.2, GUCCIARDI, D.1

1. *Curtin University* 2. *Aristotle University, Greece*

Introduction Our statistical review of the literature (Ntoumanis et al., 2014) showed that relatively little research on doping in sport has examined the contributing role of social environments. Recent research (e.g., Bartholomew et al., 2011) has utilized the self-determination theory framework (Deci & Ryan, 2002) to show how adaptive and maladaptive coach motivational strategies predict a number of indices of athlete psychological and physical functioning (e.g., disordered eating, burnout, depression). However, it is unknown how coach adaptive and maladaptive motivational strategies relate to athletes' intention and engagement in doping behavior. Hence, our study draws from self-determination theory to address this gap in the literature. Methods Data collection took place in Australia and Greece at the beginning of the sport season. In Australia 211 athletes (140 males) from a variety of sports completed the survey ($M_{age} = 22.69$ years; $SD_{age} = 5.72$). In Greece 237 athletes (146 males) provided responses ($M_{age} = 21.99$ years; $SD = 3.9$). The majority of athletes

were competing at a state or national level. Athletes completed a questionnaire pack containing a number of validated questionnaires. All procedures were carried out in accordance with APA ethics guidelines. Results Structural equation modeling analysis provided support for a model in which perceptions of autonomy supportive coaching environment positively predicted athletes' perceptions of psychological need satisfaction. Controlling coach environments were predictors of experiences of thwarted/frustrated needs. Thwarted needs were positive predictors of moral disengagement, antisocial attitudes and intention to dope. The opposite pattern of results was observed for need satisfaction and these outcomes. A number of country differences in these findings emerged. Discussion Results from this study can inform interventions that aim to provide coach anti-doping education from a self-determination perspective, in terms of creating optimal coaching environments that support athletes' psychological needs. THE IMPORTANCE OF ACHIEVEMENT GOAL ORIENTATION WHEN LEARNING A NOVEL, AND INCREASINGLY COMPLEX, SKILL

MEHUS, I., SÆTHER, S.A.

Norwegian University of Science and Technology

Purpose of the study Previous studies have shown that high ego orientation might lead to maladaptive strategies in achievement situations like organized sport (Roberts, 2012). There are, however, few studies investigating the relationship between goal orientation and learning new skills. The purpose of this study was to investigate if the degree of ego- and task orientation is connected to the ability of learning a novel skill. Another purpose was to investigate if there would be different outcomes when manipulating the complexity of the skill. Methods University students (N=40, 37.5% female) took part in a training study as part of an introductory course in Sport Science. Participants were introduced to Sport Stacking, and taught the increasingly complexed tasks of stacking the 3-3-3, the 3-6-3, and the Cycle-stack. None of the participants had tried Sport Stacking before. Skills in each task were tested at baseline by allowing each participant ten tries at each stack, and logging the last three times as a measure of outcome. Participants then took part in a five-week supervised training program, before conducting a final test of their skills. The outcome measure of learning is the difference between baseline and final test. To measure ego- and task orientation of the participants, the Perception of Success Questionnaire (POSQ; Roberts, Treasure & Balague, 1989), was administered. Results A series of independent t-tests were conducted in order to check for differences between male and female participants on central study variables. There were no differences on achievement goals or Sport Stacking skills. Correlation analysis was used to check for a connection between ego- and task orientation and Sport Stacking skills, showing no significant relationship between task orientation and Sport Stacking skills. There was however, a significant negative relationship between ego-orientation and the most complexed skill (the Cycle-stack) ($r=-.50$, $p<.05$). Discussion Results in the present study indicate that, when learning a novel skill, there needs to be a certain complexity involved before goal orientation matters. When the skill becomes relatively complexed, having a strong ego orientation appears to have a negative relationship with the learning outcome. Thus, results in the present study indicate that having a strong ego orientation leads to maladaptive strategies for learning novel skills. References Roberts, G.C. (2012). AUTONOMOUS MOTIVATION AND SELF REGULATED LEARNING: DETERMINING FACTORS OF PERFORMANCE IN SNOWBOARD AND FREESKIING

SOMMER, M.

Umeå University

Snowboard and freeskiing seem to represent a somewhat different training-culture compared to 'traditional' winter sports. Due to the absence of a typical coach utilizing customary coaching-strategies including provision of structure, instructions and feedback as tools for performance enhancement, these riders are required to take greater responsibility and control of their own learning processes. The aim of the present study was to investigate the existence of self-regulated learning (SRL - e.g. Toering, et al., 2009) and autonomous motivation (AM) (Self-determination Theory; Ryan & Deci, 2002) within this culture, and how these variables relate to development and skill level. Methods Forty-three snowboarders and freeskiers aged 15-23 years ($M = 17.5$, $SD = 1.8$), completed two questionnaires related to motivation (Behavioural Regulation in Sport Questionnaire – BRSQ; Lonsdale, et al., 2008) and SRL (Self-regulated learning questionnaire – SRLQ; Toering et al., 2013) during the on-snow season. BRSQ was distributed at the beginning (T1), mid (T2) and at the end of the season (T3). SRLQ was distributed at T2 and T3. The riders' current skill level, and seasonal development, which is a cumulative score of technical-(skill), tactical- (deliberateness), mental- (involvement) and physical (strength, agility) abilities, was rated by their coaches at T3. Results AM at T1, T2 and T3 was found to positively correlate with SRL at T3. Both SRL at T2 and T3 correlated positively with skill level. Regression analyzes indicate that AM at T1 may predict coach-rated development ($B = 0.65$, $p = 0.03$, $R^2 = 0.12$), but not skill level. In turn, SRL at T2 was found to have a positive effect on skill level ($B = 1.15$, $p = 0.05$, $R^2 = 0.14$), but not coach-rated development. Discussion Snowboarders and freeskiers display a high degree of AM, and in large part self-regulate their learning and development. Although not explicitly identified in the present study, the positive relation between AM and SRL, in combination with the separate effects of AM and SRL on development and skill level, indicate that SRL function as a mediating variable between motivation and skill level. The present results signify the importance of a training environment that facilitates autonomy and self-regulation in these sports. References Lonsdale C, Hodge K, & Rose EA. (2008). OVERTAKING BEHAVIOUR IN ELITE AND SUB-ELITE 1500M SHORT TRACK SPEED SKATERS

AL, M.1,2, KONINGS, M.J.1, DE JONG, R.1,2, HETTINGA, F.J.1

1.University of Essex, 2.The Hague University of applied sciences

Introduction Pacing can be seen as a continuous decision-making process related to how and when to invest your energy (Smits et al, 2014). Previous studies explored pacing behaviour as well as tactical positioning in short track speed skating competitions, and indicated

that tactical positioning in the final stages of the race was highly related to finishing position in 1500m races (Konings et al., 2016). As a next step in understanding pacing and tactics in head to head competition in short-track speed skating, the present study explored overtaking behaviour of elite and sub-elite short track speed skaters in 1500m races. Methods Intermediate positional rankings of 1500m races (13,5 laps) were collected per lap from short track speed skating World Cups, European and World Championships over the seasons 11/12 until 14/15 (N=7157 individual races). Short track speed skaters with a top 10 World Cup ranking were classified as elite speed skaters (ELITE; N=35 athletes, 716 individual races), while short track speed skaters with a World Cup ranking between 20-30th place were classified as sub-elite short track speed skaters (SUB; N=34 athletes, 392 individual races). The mean number of overtakings, being overtaken and total changing of positions (sum of overtaking and being overtaken) were calculated using the intermediate positions. Differences between elite and sub-elite short track speed skaters in overtaking frequency per lap were determined using independent T-tests ($P<0.05$). Results ELITE overtook their opponents less frequently in lap 1 compared to SUB (ELITE= 0.2±0.2; SUB= 0.4±0.2, $P=0.001$). In contrast, ELITE showed a higher number of overtakings in lap 10 (ELITE= 0.2±0.1; SUB=0.1±0.1, $P<0.001$) and lap 12 (ELITE= 0.2±0.1; SUB=0.1±0.1, $P=0.002$) compared to SUB. ELITE were overtaken more frequently than SUB in lap 1 (ELITE= 0.5±0.2; SUB= 0.4±0.2, $P=0.004$), but less frequently in lap 11 (ELITE= 0.1±0.1; SUB= 0.1±0.1, $P<0.001$), lap 12 (ELITE= 0.1±0.1; SUB= 0.1±0.1, $P=0.046$) and lap 13 (ELITE= 0.1±0.1; SUB= 0.1±0.1, $P=0.022$). Finally, no differences were found in the total changing of positions between ELITE and SUB. Conclusion The present study showed that elite short track speed skaters distinguished themselves from sub-elite short track speed skaters by demonstrating on average both a higher number of overtakings as well as being overtaken less frequently by their opponents in the final, decisive part of the race. THE POSITIONING BEHIND ONE'S FORERUNNER IN THE FINAL STAGES OF THE RACE DISTINGUISHES ELITE AND SUB-ELITE SHORT TRACK SPEED SKATERS

DE JONG, R.1,2, KONINGS, M.J.1, AL, M.1,2, HETTINGA, F.J.1

1.University of Essex, 2.The Hague University of Applied Sciences

Introduction Pacing can be seen as a continuous decision-making process related to how and when to invest your energy (Smits et al., 2014). Previous research explored the pacing strategies of short track speed skaters and emphasized the importance of tactical positioning (Konings et al., 2016). In addition, the positioning behind one's forerunner might be crucial in order to provide oneself the opportunity to overtake the forerunner. The present study explored how elite and sub-elite short track speed skaters positioned themselves behind their forerunner. Methods Lap times and intermediate positions of 1500m races were collected from short track speed skating World Cups, European and World Championships over the seasons 11/12 until 14/15 (N=7157 individual races). Short track skaters were classified by proficiency: skaters with a top 10 World Cup ranking were classified as elite (ELITE; N=35 athletes, 716 individual races), while skaters with a World Cup ranking between 20-30th place were classified as sub-elite (SUB; N=34 athletes, 392 individual races). The positioning behind one's forerunner was determined by calculating the time the forerunner preceded the participant in every lap. Differences between elite and sub-elite riders in the positioning behind one's forerunner were determined using independent t-tests ($p<0.05$). Results SUB positioned themselves closer behind their forerunner in the first three laps compared to ELITE (Lap 1: SUB=0.13±0.07 sec vs. ELITE=0.15±0.08 sec, $P=0.001$; Lap 2: SUB=0.13±0.06 sec vs. ELITE=0.14±0.08 sec, $P=0.021$; LAP 3: SUB=0.12±0.05 sec vs. ELITE=0.13±0.08 sec, $P=0.006$). In contrast, ELITE positioned themselves closer behind their forerunner in the last four laps (Lap 11: ELITE=0.10±0.07 sec vs. SUB=0.14±0.12 sec, $P<0.001$; Lap 12: ELITE=0.11±0.09 sec vs. SUB=0.18±0.20 sec, $P<0.001$; Lap 13: ELITE=0.15±0.15 sec vs. SUB=0.27±0.31 sec, $P<0.001$; Lap 14: ELITE=0.21±0.31 sec vs. SUB=0.47±0.66 sec, $P<0.001$). Discussion Elite short track skaters appeared to be able to position themselves closer behind their forerunner compared to sub-elite skaters during the final, decisive stages of the race. Our findings emphasize the importance of tactical positioning in short track speed skating competitions, and propose the positioning behind one's forerunner in the final, decisive stages of the race as a distinguishing factor between elite and sub-elite short track speed skaters. OP-PM05 Brain & Cognitive Function

EFFECTS OF EXERCISE-INDUCED HYPOHYDRATION ON BRAIN STRUCTURE AND FUNCTION IN ENDURANCE-TRAINED ATHLETES USING MRI

TAN, X.R.1, LOW, C.C.1, STEPHENSON, M.C.2, KOK, T.2, SOONG, T.W.1, LEE, J.K.W.1,3

National University of Singapore

Affiliations 1National University of Singapore 2Agency for Science, Technology Research, Singapore. 3DSO National Laboratories, Singapore Introduction Hypohydration exceeding 2% body mass is known to impair endurance performance (Sawka et al., 2001; Cheuvront et al., 2010). It is hypothesized that the central nervous system, specifically the brain, is negatively affected by hypohydration, leading to an impairment in endurance capacity. To date, few brain imaging studies have investigated the functional impact of exercise-induced hypohydration and this precipitates the main objective of this study. Methods Ten endurance-trained sportsmen (mean \pm sd: age 23.3 \pm 1.1 years; body fat 10.5 \pm 2.4%; VO₂peak 65.6 \pm 5.0 ml kg⁻¹ min⁻¹) were dehydrated to -3% body mass by running on a treadmill at 65% VO₂peak in a 25°C environment, before drinking to replace 100% or 0% of fluid losses in two separate randomized, counterbalanced trials. Participants underwent MRI scans at baseline and post-fluid replacement for assessment of brain volume and fMRI imaging during a plantar flexion task. Endurance capacity was assessed by running to exhaustion at 75% VO₂peak. Core temperature, heart rate and endurance timings were assessed using paired sample T-test with $p<0.05$ considered significant. Results Results from the endurance run showed similar heart rates between the euhydrated (EU) and hypohydrated (HH) trials at time of exhaustion (EU: 171 \pm 10 bpm, HH: 172 \pm 9 bpm; $p=0.184$). Core temperature before the start of endurance run were similar between conditions (EU: 36.7 \pm 0.2°C, HH: 36.7 \pm 0.3°C; $p=0.836$). The absolute change in core temperature in the endurance run were similar between trials (EU: 2.7 \pm 0.2°C, HH: 2.7 \pm 0.3°C; $p=0.939$). However, the rate of increase in core temperature was higher in hypohydrated subjects (EU: 0.06°C min⁻¹, HH: 0.07°C min⁻¹; $p=0.006$). Endurance capacity was reduced with hypohydration (EU: 45.2 \pm 9.3 min, HH: 38.4 \pm 10.7 min; $p=0.033$). Fold changes in total

brain volume were lower in HH trials than EU trials (EU: 1.007, HH: 0.993; p=0.003). BOLD (blood-oxygen-level dependent) activation in the precentral gyrus (motor), postcentral gyrus (somatosensory) and supplementary motor area (SMA) during the plantar flexion task were similar between conditions (PreCG: p= 0.314, PostCG: p=0.332, SMA: p=0.677). Conclusion Our findings demonstrate that the cardiovascular system is remarkably defended in endurance-trained athletes despite loss of body fluids. Total brain volume is reduced with hydration but notably the functional activity of the brain is well-preserved in these endurance athletes. The decline in endurance capacity could possibly be due to other factors such as the greater heat strain accumulated in hypohydrated individuals. References: Sawka et al. (2001). Comp. Biochem. CEREBRAL OXYGENATION DURING CORTICAL ACTIVATION: THE EFFECT OF THREE EXERCISE TRAINING MODALITIES

TERBLANCHE, E., COETSEE, C.

Stellenbosch University

Introduction Research on the influence of exercise training on cerebral oxygenation patterns is inconsistent and not well understood. Physical training induces structural brain changes as well as functional changes in neural networks essential for cognitive processing. It is, however, uncertain how the changes relate to cognitive performance and it remains to be established if these patterns are training mode dependent. The primary aim of this study was to determine if the exercise training mode has a differential effect on older individuals' cerebral oxygenation during cortical activation. Methods Sixty seven inactive individuals (55 to 75 years) volunteered for this intervention study. Participants were allocated to a resistance training (RT) group (n=22), high-intensity interval training (HIIT) group (n=13), moderate continuous training (MCT) group (n=13) and a control (CON) group (n=19). Each training group performed three supervised exercise sessions per week for a period of 16 weeks. Near-infrared spectroscopy (NIRS) was used to measure cerebral oxygenation during a simple and complex cognitive task. Data were analysed using mixed model repeated measures ANOVA and P < 0.05 was considered statistically significant. Cohen's effect sizes were calculated to compare the magnitude of differences in outcome variables between the groups. Results CON showed higher relative O₂Hb values during the simple and complex Stroop tasks during post-test (ES = 0.76 and 0.62, respectively; P < 0.05). MCT showed a decrease in O₂Hb on the simple (ES = 0.48; P > 0.05) and complex (ES = 0.50; P > 0.05) tasks. The HIIT groups' O₂Hb on the simple task decreased from pre-test (ES = 0.45; P > 0.05). MCT showed an increase in HHb on the simple (ES = 0.89; P < 0.05) and complex (ES = 1.14; P < 0.05) cognitive tasks. HIIT exhibited a smaller decrease in the concentration of HHb compared to pre-test measurements on the simple (ES = 0.67; P > 0.05) and complex tasks (ES = 0.49; P > 0.05). The RT group did not show any significant changes in their activation patterns during the simple or complex task when comparing pre- and post-test values (ES < 0.3; P > 0.05). Discussion Sixteen weeks of high-intensity interval training and moderate continuous aerobic training improved task-efficient cerebral oxygenation and oxygen utilization during cortical activation in older individuals more than resistance training. These findings may reflect the different neural-cognitive mechanisms involved with different modes of exercise training. It has been suggested that aerobic training is linked to elevated levels of BDNF, while resistance training produces increased levels of IGF-1. However, it is unclear whether these differences account for the varying responses in cerebral oxygenation observed in this study. et2@sun.ac.za

A QUALITATIVE COMPARISON OF ELITE TAEKWONDO PLAYERS: DOES FIGHTING IN TRAINING ADEQUATELY SIMULATE THE COGNITIVE-EMOTIONAL CONSTRAINTS OF COMPETITION?

MALONEY, M., FARROW, D., RENSHAW, I.

Australian Institute of Sport

Introduction The importance of designing training tasks that simulate the cognitive-emotional constraints and demands of competition has recently been highlighted (Headrick et al., 2014). Fighting is a key training task of combat sports, however no research has examined whether the constraints of this task adequately simulate the cognitive-emotional demands of competition. The aim of this study was to use the qualitative course-of-action methodology to explore how the cognitive-emotional responses of elite taekwondo athletes differ between fighting in competition and fighting in training. Methods Five international (world ranking 11.2 ± 2.2; age 26.8 ± 4 years) and three national level taekwondo players (world ranking 165 ± 97.9; age 18.3 ± 1 year) were video-taped completing a typical fight in competition and a typical fight in training. Following each fight, players participated in a video-facilitated self-confrontational interview where they were asked to comment on the perceptions, thoughts and feelings that influenced each action. Data were analysed using a course of action approach (Theureau, 2002). Each condition was analysed separately and then compared for differences. Firstly, comments relevant to an action were organised into discrete units, termed elementary units of meaning (EUM). Consecutive relatable EUMs were joined together into sequences, with common sequences then grouped together as themes. Themes unique to either the training or competition environment were identified. Results Results revealed the emergence of several themes unique to either competition or training fights. Unique competition themes: Ego goal orientation, aggression, mental effort, physiological arousal and anxiety. Unique training themes: Mastery focus, low stimulation and opponent familiarity. Discussion Findings highlight the contextualised nature of cognitive and emotive responses, which emerged from the interaction between the actor and environment. Our interpretation suggests that simply fighting in training does not produce cognitive-emotive responses representative of competition, perhaps due to players being familiar with their team mates and having different goals. Further work needs to empirically test the identified themes and consider how fighting in training can better simulate the constraints and demands of competition. THE EFFECTS OF A SINGLE BOUT OF EXERCISE ON MOTOR MEMORY INTERFERENCE IN THE TRAINED AND UNTRAINED HEMISPHERE

LAUBER, B.1,2, TAUBE, W.2, GOLLHOFER, A.1

1 University of Freiburg, Department of Sport and Sport Science, Germany, 2 University of Fribourg, Department of Medicine, Movement and Sport Science, Switzerland

Aim Increasing evidence suggests that cardiovascular exercise has positive effects on motor memory consolidation. In this study, we investigated whether a single session of high-intensity interval training mitigates the effects of practising an interfering motor task. Furthermore, learning and interference effects were assessed in the actively trained and untrained limb, as it is known that unilateral motor

learning can cause bilateral adaptations. Methods A total of 30 subjects were divided into three groups and equally distributed based on their fitness level determined during a graded VO_{2max} test 1 week prior to the experiment. Subsequently, subjects performed a ballistic training comprised of 45 contractions aiming to increased their rate of force development. This was followed by a single session of high-intensity interval training (4x4min at 75% of the max workload obtained during the VO_{2max} test) either before (Group 1) or after (Group 2) practising an interfering accuracy task (visuomotor tracking). The control group (Group 3) did not participate in the HIIT, but rested instead. Performance in the ballistic task was tested before and after the ballistic training, after the exercise and practise of the accuracy task, and 24 hours later. Results After ballistic training, all groups showed comparable increases in performance in the trained ($98.1 \pm 30.5\%$) and untrained limb ($71.5 \pm 25.7\%$). Despite the practise of the accuracy task, Group 1 ($-4.9 \pm 6.1\%$, $p = 0.39$) maintained their ballistic task performance after the high-intensity interval training, whereas Groups 2 ($-21.57 \pm 5.80\%$, $pK=0.01$) and 3 ($-13.69 \pm 5.28\%$, $p = 0.01$) showed significant interference effects. After 24 hours, Group 1 still did not show any interference effects. Group 2 counteracted the interference, resulting in increased in ballistic task performance ($+43.94 \pm 12.80\%$, $p < 0.01$) so Group 1 ($142.23 \pm 46.21\%$) and Group 2 ($142.07 \pm 29.45\%$) had significantly higher overall ballistic learning rates compared to Group 3 ($47.38 \pm 21.24\%$). The results were similar in the trained and untrained limb. Conclusion A single session of cardiovascular exercise can prevent motor interference in the trained and untrained hemisphere, irrespective of whether it is performed before or after the interfering motor task.

RESTING EEG MICROSTATES CHANGES AFTER ACUTE EXERCISE

SPRING, J., TOMESCU, M.I., BARRAL, J.

University of Lausanne; University of Geneva

Introduction Multichannel electroencephalography (EEG) recording during relaxed wakefulness is a promising neuroimaging technique to investigate spontaneous brain activity changes after exercise. EEG microstates analyses showed that the majority of signal can be explained by only four stable microstates (Lehmann et al., 2009). The temporal characteristics of the microstates have a neurophysiological relevance in humans. Thus, this study aims to identify the effect of physical exercises on microstates temporal features. Methods Twenty triathletes performed two successive exercises on a cycle ergometer: a 30 minutes moderate exercise at 60% of the maximal aerobic power, and a 10 kilometres time trial. Before (PRE), between (POST1) and after (POST2) the two sessions, spontaneous resting EEG was recorded by using 64 surface electrodes during 3 minutes. Muscular artefacts were manually excluded from the signal, and Independent Component Analysis was applied to remove eye-blinks and cardiac artefacts. The data were down-sampled to 128 Hz and bad electrodes were interpolated. The three initial datasets were concatenated into one file and submitted to a k-means clustering to identify the 4 dominant microstates by using Cartool software (Brunet et al., 2011). Those maps were back fitted to the initial datasets to compare microstates between conditions in term of mean duration (ms), relative time coverage (%), and frequency of occurrence (nb/s). Results The analyses revealed that the four cluster map solutions (named A, B, C, D) explain above 84% of the global topographic variance. ANOVAs indicated significant Time by Map interactions for the mean duration ($F(6,114)=7.5$, $p<0.001$) and the relative time coverage ($F(6,114)=7.4$, $p<0.001$) of map C only. Bonferroni post-hoc tests revealed that both variables increase at POST1 and POST2 compared to PRE. No significant effects were obtained for the frequency of occurrence. Discussion This is the first study that assesses the effect of an acute endurance exercise on EEG microstates features. Microstates C was previously shown to correspond to a specific network with main generators in the anterior cingulate and the insula cortices (Britz et al., 2010). These results are in line with the literature as these regions are involved in the integration of sensory feedback and emotional information. Thus, the increase duration and relative time coverage of microstate C could reflect the exercise-related afferent activity. References Britz, J., Van de Ville, D., & Michel, C. M. (2010). EXERCISE AND VIGILANCE: INFLUENCE OF CARDIOVASCULAR FITNESS AND SPORT PARTICIPATION.

BALLESTER, R.1, PABLOS, C.1, LLORENS, F.2, HUERTAS, F.1

1: Catholic University of Valencia

Introduction Vigilance or sustained attention is the capacity to maintain attention over time and react efficiently to relevant stimuli (Gunzelmann et al., 2010). The study of vigilance is highly important since optimal levels of this capacity are necessary in many day life activities such as attending to academic lessons (Trautmann & Zepf, 2012) or performing efficiently in certain sport settings (Voss et al., 2010, for a review). Indeed, the regular practice of exercise has been related to vigilance across the life span (e.g., Ballester et al., 2013; Luque-Casado et al., 2013). Methods Two studies have been carried out with different groups of children and adolescents differentiated in terms of their regular sports participation (athletes, football players and sedentary controls). Participants completed the Psychomotor Vigilance Task (PVT) to evaluate their vigilance performance. In a different session, participants performed the Léger Multi-stage fitness test to estimate their aerobic fitness level. Results Both children and adolescent football players showed better cardiovascular fitness than sedentary controls in the Léger test (all $p < .001$). In the first study, adolescent football players exhibited faster responses in the PVT than sedentary controls $F(1,71) = 17.27$, $p < .001$, $\eta^2_{partial} = .19$. In the second study, athletes showed faster RTs in the PVT than sedentary controls ($p < .001$), and football players outperformed both athletes and sedentary controls (both $p < .001$). Discussion The major novel finding of our investigation points to a positive relationship between sport participation and vigilance performance during childhood and adolescence. We discuss our results in terms of the two different hypotheses ("cardiovascular fitness" and "cognitive component skills") put forward in the literature to explore the relationship between regular exercise and cognitive functioning. OP-BN04 Exercise in Elderly: Balance & Running

BALANCE TRAINING INDUCES HIGHLY TASK-SPECIFIC NEURAL PLASTICITY

GIBOIN, L.S.1, KRAMER, A.1, HASSA, T.2, SCHÖNFELD, A.3, DETTMERS, C.2, GRUBER, M.1

Universität Konstanz, 2. Department of Neurorehabilitation, Kliniken Schmieder, Allensbach; 3. Leibniz-Institut für Neurobiologie, Magdeburg

Introduction There is growing evidence that improvements in performance after short-term balance training occur only in the trained task (Giboin, Gruber, & Kramer, 2015), and it has been suggested that this task-specificity has a neuronal origin. However, task-specific neural plasticity after balance training has not been demonstrated yet. In the present study we tested the hypothesis that learning to walk and balance on a slack-line induces specific neural adaptations only for this task. **Methods** We measured the amplitude of H-reflexes in the soleus muscle (SOL) during a trained (slackline) and an untrained balance task (tilt-board) before and after six weeks of slackline training (3 times 30 min per week) in a training group ($N=15$) as well as in a control group ($N=13$), which did not train. We established comparable conditions between the tasks and for the pre and post measurements by giving the stimulation during the preparatory phase of the balance task, i.e. just before the foot of the subject touched the balance device. Background EMG of the SOL and tibialis anterior muscle (TA) and the angle of the right knee and ankle were measured at stimulation to ensure comparable conditions. To assess the effect of training on a behavioural level, the number of steps on the slackline and the duration of equilibrium on the tilt-board were measured before and after the training. **Results** Three ways ANOVA with mixed design showed: i) a task ($p<0.01$), time ($p<0.01$) and group*time effect ($p<0.001$) on performance. Post hoc tests showed that the increase in performance occurred only for the training group and only for the trained task (slackline, $p<0.001$). ii) No effect of time for the background EMGs nor the knee and ankle angles at the time of stimulation was detected, indicating comparable conditions for the stimulations pre and post training. A two ways ANOVA with mixed design showed an effect of training on the amplitude of the H post expressed in percentage of the amplitude of the H pre training (task effect, $p<0.05$). Post hoc paired T tests showed that the H reflex was reduced only in the training group during the slackline task ($p<0.05$). **Conclusion** In line with previous studies we found an increased performance only in the trained task. Only during the trained task we observed a modulation of the H-reflex without any differences in the ankle and knee angles and the background EMGs for the pre vs. the post training measurements. Thus, we assume that the modulation of the H-reflex most probably reflect training-induced neural plasticity. We suggest that the training of a specific balance task, here walking on a slackline, induces plasticity at spinal level, which might, at least in part, explain the specificity of the improvement observed on the behavioural level. Giboin, L. S., Gruber, M., & Kramer, A. (2015). Task-specificity of balance training. *Hum Mov Sci*, 44, 22-31. doi:10.1016/j.humov.2015.08.012

BEHAVIORAL AND NEUROPHYSIOLOGICAL RESPONSIVENESS OF OLDER ADULTS TO BALANCE TRAINING

RUFFIEUX, J., MOUTHON, A., KELLER, M., WÄLCHLI, M., TAUBE, W.

University of Fribourg

Normal aging involves structural and functional deteriorations in all systems relevant for postural control leading to impairments in postural stability. It has been shown that balance training can counteract these impairments. However, only very few studies have investigated the neural correlates of such behavioral adaptations in older adults. The available literature suggests that older adults show an increase in spinal reflex excitability and a decrease in corticospinal excitability after balance training. The present study aimed to shed more light on neural adaptations in response to balance training in older adults. To this end, we measured spinal and cortical excitability and postural stability in older adults (65-80 years) before and after 5 weeks of balance training (training group, TG) or habitual activity (control group, CG). An H-reflex recruitment curve was recorded from m. soleus during upright standing to evaluate changes in spinal reflex excitability. To investigate changes in the excitability of direct (monosynaptic) corticospinal pathways, we conditioned the H-reflex by TMS during a fast backward translation of the support surface. Behavioral results, showed significant interactions of session and group in the more challenging one-legged tasks which were due to the TG performing better and the CG performing worse in the post-session. The H-reflex was significantly reduced in the post-session. This effect was mainly due to the CG although the interaction of session and group did not reach significance ($p = 0.09$). Conditioning of the H-reflex led to an early facilitation in all subjects. Although the facilitation was slightly decreased in the TG and slightly increased in the CG after training, there was no significant session or group effect. Our results confirm that older adults' postural stability can be improved by training. Although neural adaptations failed to reach significance in this study, the adaptations in the TG relative to the ones in the CG follow the trend of existing studies showing greater spinal and reduced corticospinal excitability after training. This could be interpreted as a reversion of age-related changes in these neural pathways. Interestingly, in this study, the effects were often not primarily due to the TG showing large adaptations but to the CG showing inverse effects. This was true for behavioral as well as for neural adaptations. In this regard, the results are consistent. However, the reasons for the changes in the CG remain unclear. It seems that neural adaptations occur at a slower rate in older adults than in young. It can thus be speculated that the training period of this study was too short to induce significant changes, even more since existing studies had longer intervention periods. SPRINT ACCELERATION MECHANICS IN MASTER ATHLETES: A PILOT STUDY.

MORIN, J.B.1, PANTOJA, P.2, BRISSWALTER, J.3, PEYRÉ-TARTARUGA, L.A.2, SAEZ DE VILLARREAL, E.3

University of Nice Sophia Antipolis

Introduction Even in well-trained individuals, sprint performance decreases with age, the best performances being usually reached between 20 and 30 yrs (Arampatzis et al., 2011; Rittweger et al., 2009). Although this inevitable decrease in performance has been related to decreases in muscular force, velocity and power capabilities, these have not been measured in the specific context of all-out sprinting (Korhonen et al., 2006; Korhonen et al., 2009). The aim of this pilot study was to investigate the sprint acceleration mechanical outputs of Master sprinters to better understand the mechanical underpinnings of the age-related decrease in sprint performance. **Methods** The study took place during an international Masters competition. Horizontal ground reaction force, velocity, mechanical power outputs and mechanical effectiveness of force application were measured during a 30-m sprint acceleration (Samozino et al., 2015) in twenty-eight

male sprinters (39 to 96 yrs). Age-related changes were presented and compared to elite young sprinters data (Rabita et al., 2015). Results Maximal force, velocity and power outputs decreased linearly with age (all $r^2>0.71$; $P<0.001$), at an $\approx 1\%$ per year rate. The maximal effectiveness of horizontal ground force application also decreased with age. However, its decrease with increasing velocity within the sprint acceleration was not age-dependent. The maximal power output of the oldest subject tested was about 9 times lower than that of younger world-class sprinters (3.57 vs. 32.1 W.kg $^{-1}$). Discussion In addition to lower neuromuscular force, velocity and power outputs, Master sprinters had an impaired effectiveness of ground force application (i.e. less horizontal orientation), especially at the beginning of the sprint. These mechanical variables explain the linear decrease in sprint performance with age in trained Master athletes, and these results provide insights into effective training methods for this specific population. MOVEMENT SPECIFIC REINVESTMENT, STEPPING BEHAVIOR AND VISUOMOTOR CONTROL DURING WALKING IN OLDER ADULTS WITHOUT HISTORY OF FALLING

UIGA, L.1,2, RYU, D.1, CAPIO, C.1,2, YOUNG, W.3, WONG, T.1,2, TSE, A.4, WILSON, M.5, MASTERS, R.1,2

1:HKU (Hong Kong), 2:University of Waikato (NZ), 3:Brunel University London (UK) 4:IED (Hong Kong) 5:University of Exeter (UK)

Introduction Reinvestment refers to the use of self-focused attention to consciously monitor and control movements during performance. Ironically, conscious effort often leads to performance breakdown. We have previously shown that older adults who had not fallen but displayed high propensity for movement specific reinvestment were more aware of their limb movements and less aware of the external environment during walking than those who displayed low propensity for reinvestment (Uiga et al., 2015). The aim of this study was to examine whether such inward focus of attention by high reinvestors in comparison to low reinvestors is characterised by differences in visuomotor control. We measured gait and gaze behavior of older adults with high or low propensity for reinvestment during walking. Methods Based on their scores on the Movement Specific Reinvestment Scale (Masters et al., 2005), older adults with no fall history were divided into high ($n=25$) and low ($n=26$) reinvestors. They were required to perform 30 walking trials on a 4.8-m pathway, in which they had to step on the middle of a target as accurately as possible and navigate between two obstacles. Participants' gait kinematics (stepping characteristics and stepping on target accuracy), gaze behavior (number and duration of fixations on the target and obstacles), and the time difference between saccadic offset from the target and the heel contact in the target were measured. Results Results show that high reinvestors displayed lower walking velocity ($p=.05$), decreased stepping on target accuracy ($p=.005$) and longer foot contact with the target ($p=.031$) compared to low reinvestors. There were no significant differences in gaze behavior variables and saccadic offset from the target and heel contact with the target ($p's>.05$). Discussion Our results suggest that older adults with high propensity for reinvestment display impaired gait behavior already before falling compared to older adults with low propensity for reinvestment. These gait differences were not accompanied by disparities in gaze behavior. Future research is recommended to identify other factors that could influence gait behavior of high reinvestors. REVERSAL OF AGE-RELATED "SLOWING" OF EEG POWER THROUGH VIDEOGAME-BASED TRAINING

GENNARO, F., SCHÄTTIN, A., ARNER, R., DE BRUIN, E.D.

Institute of Human Movement Sciences and Sport, ETH Zürich

Introduction Age-related "slowing" of EEG power results in increased slow frequencies power and might reflect impaired cognitive processing and functional brain connectivity [1][2]. Motor skill training with videogame-based training (VGT) is hypothesized to ameliorate motor and cognitive deficits in older adults [3]. Neuro-electrical adaptations following VGT in older adults remain unclear. This study investigated and compared eight weeks VGT with conventional Balance training (BT) on EEG frequencies power, measured during a divided attention task. Methods 27 older adults (79 ± 7 years) were randomly assigned to VGT / BT, both lasting 8 weeks with three 30 min training sessions per week. Subjects performed a divided attention task involving auditory and visual stimuli (TAP, PSYTEST, Herzogenrath) pre and post intervention. EEG was measured with a portable device (Alpha-Active Ltd, Devon, UK) and two electrodes on the prefrontal cortex (channels: Fp1 & Fp2 / 10-20 system). EEG analysis of clustered Fp1-Fp2 was performed event-locking auditory and visual stimuli in 4s epochs (-1500 ms pre- and 2500 ms post-stimulus) analyzed separately. Relative Power (RP) of DELTA (δ : 1 - 3.5 Hz), THETA (θ : 3.5 - 7.5 Hz), LOWER ALPHA (α LOW: 7.5 - 10 Hz), UPPER ALPHA (α UP: 10 - 12.5 Hz) and BETA (β : 12.5 - 30 Hz) were calculated and normalized, along with all the possible Ratio (RP-Ratio) combinations. Statistical analysis was performed with Puri and Sen L ANOVA statistics for ranked data [4]. Results Both RP and RP-Ratio revealed significant interaction effects in favor of VGT, specifically in θ RP ($L = 6.23$, $p = 0.007$) and α LOW / β RP-Ratio ($L = 6.27$, $p = 0.006$). A significant main time effect for VGT was observable in these measures: θ RP ($L = 3.38$, $p = 0.032$); α LOW / β RP-Ratio ($L = 3.01$, $p = 0.049$). Wilcoxon Signed Rank Test showed an intra-group pre-to-post difference with medium-to-large effect size after VGT; θ RP and α LOW / β RP-Ratio ($p = 0.016$, $r = -0.57$ & $p = 0.031$, $r = -0.53$, respectively). Discussion Following VGT, individuals exhibited post-intervention decrease in slow waves (θ RP) as well as reduced slow-to-fast frequencies (α LOW / β RP-Ratio), that was more evident in this group compared to Balance. Results suggest that an 8 weeks VGT intervention may ameliorate age-related "slowing" of EEG power. Further research is warranted that assesses whether the changes underlie improvements in cognitive information processing and functional brain connectivity. References [1] Rossini et al. SOCIALIZATION INTO FORMAL AND INFORMAL SPORTS AND THE ROLE OF SOCIAL BACKGROUND AND MEDIA USE OF ADOLESCENTS

BRAUMÜLLER, B.

German Sports University Cologne

Sporting (in)activity of teenagers and young adults doesn't appear by chance, it is rather developed in socialization processes and influenced by the social background. The social background reflects socio-structural aspects that can determine sports engagement, e.g. gender, age, migrant background, cultural and social capital. According to interactional models of socialization, engagement in sports is also shaped in the productive processing of interior and exterior realities of individuals. The interior reality relates to physical and mental conditions that appear in individual orientations and competencies. Focusing on the socialization into sports the motives for physical activity and the self-concept of athletic skills are interior factors (Baur et al 2004). The exterior reality reflects the social and ecological context, in which individuals are imbedded, e.g. requirements, conditions and social opportunity structures. In terms of sports-socialization physical activities of family and friends, parental support, peers and (media-related) leisure activities can affect the sporting (in)activity of adolescents. Especially in the youth peers and media are important mediators and impact the personality development and leisure behavior (Hurrelmann 2002). This holds even more true for new and social media, because they offer diverse opportunities for interaction and peer-communication that strongly influence socialization processes. Therefore using new and social media seems to be part of the exterior reality. Research questions & Methods While the impact of the three dimensions on general sports engagement as well as the effects of socio-structural factors on sports-clubs-memberships is quite well investigated, a lack of studies about the impact on other sports-settings appears in the current state of research. But this focus seems to be worthwhile, since socialization needs and structural conditions of formal and informal sports activities differ. The aim of this study is to analyze whether the process of socialization into sports, thus the productive processing of interior and exterior realities and the social background, shapes not only the general activity but also the settings in which adolescents and young adults engage in sports. The empiricism is based on a secondary data analysis of a study about cultural-, sport- and media-orientated leisure activities of German adolescents aged from 13-24 years (Grgic & Züchner 2013). Multivariate analyses will be made to identify the influencing factors on formal and informal sports engagement and to determine the role of new and social media activities in this model. MEDIA DISCOURSE OVER FOREIGN COACHES

BORGES, M., ROSADO, A., DE OLIVEIRA, R.

London South Bank University

Theoretical perspectives on migration have highlighted the dichotomy between established and outsiders and this has recently been discussed in regards to sport. Some research has focused attention on the migration of sports players and their interactions abroad, but fewer studies have examined the recruitment and integration of foreign coaches in their host country. This study explores the perspectives of host and donor countries through their media discourse. A qualitative content analysis was used to investigate how foreign coaches were represented in the media. Multiple sources were cross-referenced to capture the media and public opinions prior to, during and after national and international sport events including Premier league 2013/2014, FIFA World Cup 2014, and 2012 Olympic Games. We found 257 media texts published between April 2012 and August 2014, in four different languages. The results showed the polarisation of the media discourse with foreign coaches either portrayed as instrumental for sport development and success, or stigmatised as unsuccessful mercenaries with no attachment to the host country. Another result showed that the host media discourse was at odds with the views by foreign coaches about migration which also appeared in the media. Taken together, these results highlight the importance of cultural awareness and media training especially for coaches dealing with the media of a host country.

MEGA SPORTING EVENTS AND CHILDREN RIGHTS: THE VARIETY OF MEDIA COVERAGE IN 2014 IN 22 COUNTRIES

MOUSTAKAS, L., MÜLLER-SCHOELL, T.

Deutsche Sporthochschule Koeln

This paper examines how written media covered Mega Sporting Events (MSEs) and their impact on children rights, and human rights writ large, in 2014. Though many academic publications and advocacy organisations have examined the human rights implications of MSEs, little work has been done exploring media reporting on these issues. In an initial, exploratory fashion, articles from sources in 22 different countries were counted and scanned, aiming at a quantitative and qualitative summary of print and online reporting in 2014. Based on initial findings, we can tentatively classify media awareness of human rights issues surrounding MSEs in each country as either high, nascent or minimal. The pattern of resulting differences can be explained by enabling and limiting factors of the respective media system. We use a set of indicators for freedom, development and societal engagement with human rights issues to explain media awareness in different countries. This leads to a grouping of countries into types of awareness. Overall, the results – exploratory as they are – can give a baseline for future comparison and evaluation, orientations for further research and potential guidance for advocacy activities.

PS-PL01 Crossing the limits of impairment – lessons from neuromuscular and cardiovascular function after spinal cord injury

LIFE-LONG ACTIVITY-DEPENDENT NEUROMUSCULAR PLASTICITY IN OPTIMIZING PERFORMANCE IN THE PRESENCE OF NEUROMOTOR DISORDERS

EDGERTON, V.R., GERASIMENKO, Y., GAD, P., SAYENKO, D., TACCOLA, G., BURDICK, J., LIU, W.

University of California, Los Angeles

The robustness of the potential plasticity within the neuromuscular system and autonomic systems in human subjects with severe neuromotor deficiencies have been consistently underestimated for decades. Similarly, this underestimation has been particularly extreme in individuals that have endured these deficiencies for relatively long periods. There is increasing evidence that the level of function that can be regained in individuals four years following a traumatic or even progressive dysfunction in the sensorimotor system can be realized to a level that would be considered to be a significant improvement in the general quality of life. The lack of appreciation of this recovery potential can be traced to the absence of recognition of the impact of activity-dependent mechanisms to guide the functional recovery. There is lack of recognition of the degree to which the neural control of routine daily movements is executed largely by neural networks that function largely automatically. Further, this automaticity is now better understood given the degree of control of these networks based on the complex ensembles of sensory information that can be processed without conscious input to spinal networks. The degree to which the sensory input representing the timing and level of loadbearing on the lower limbs is an important source of input to the central nervous system in sustaining postural and locomotor control continues to be underestimated. Experiments will be described which demonstrate that after complete paralysis, the return of the experience of bipedal and quadrupedal loadbearing in response to lumbosacral stimulation can be used to function following spinal cord injury in humans. Full weight-bearing stepping in rats can be recovered in the presence of spinal epidural stimulation and pharmacological modulation largely involving serotonergic agonists. Data will be presented which demonstrates a progressive increase of the level of loadbearing on a daily basis in rats and humans can significantly enhance the level of recovery of standing potential and even voluntary control. The mechanisms of this recovery are gradually being formulated from the perspective of how spinal networks can be fine-tuned to facilitate a wide range of complex motor tasks. This fine tuning can be accomplished using a combination of neuromodulatory interventions, including multiple forms of electrical stimulation, sensory modulation and pharmacological modulation. The basic physiological concepts and proposed mechanisms underlying these results will be presented.

CARDIOVASCULAR FUNCTION DURING EXERCISE - THE SPINAL CORD INJURY MODEL

THEISEN, D.

Luxembourg Institute of Health

A complete lesion to the spinal cord implies loss of sensitive neural traffic from the periphery and of voluntary muscle mass in body regions innervated by nerves caudally to the lesion level. Furthermore, functions relying on the autonomous nervous system are affected in proportion to the spinal lesion level. In particular the cardiovascular function can be strongly impaired, with consequences for the regulation of blood pressure and body temperature. The limited active muscle mass available for exercise and the impaired cardiovascular adaptations result in dramatically reduced exercise capacity. Individuals with spinal cord injury have to rely on their upper body musculature for exercise, which limits their total oxidative capacity, maximal power output and mechanical efficiency. Blood redistribution during exercise is impaired in body regions with no autonomic nervous system control. As a result, venous return to the heart is reduced and cardiac stroke volume is limited. This increases the risk of exercise induced hypotension and induces a higher compensatory heart rate during submaximal exercise conditions. On the other hand, heart rate during maximal effort may be lower in individuals with spinal lesions above the level thoracic 6, due to impaired sympathetic drive to the heart. Individuals with complete cervical spinal lesions solely rely on parasympathetic withdrawal and circulating catecholamines to increase their heart rate, generally not exceeding 130 beats per minute. Limited neural feedback and impaired vasomotor and sudomotor function below the lesion induce greater heat storage during exercise. Strategies to promote venous return and to support body cooling have been suggested in the literature to improve exercise performance and reduce injury risk, especially for athletes with high spinal lesions. However, their applicability depends on the sport context. Recent research indicates that successful elite athletes with spinal cord injury may represent a subgroup with partially intact autonomous nervous system control, in spite of them being classified as individuals with "complete" lesions, based on motor and sensory tests. A partial preservation of autonomic function can significantly improve exercise tolerance in both athletes and non-athletes. Individuals with cervical or high thoracic lesions are at risk for autonomic dysreflexia. These acute episodes of hypertension result from a generalized sympathetic vasoconstriction below the lesion, itself a consequence of nociceptive stimulations in insensate body regions. Autonomic dysreflexia is a clinical emergency, but may be triggered by athletes to enhance their exercise performance. Its deliberate induction is considered a doping offense by the International Paralympic Committee.

OP-PM06 Nitrate & Diet Composition

DIETARY NITRATE AUGMENTS MUSCLE METABOLIC ADAPTATION TO HIGH-INTENSITY INTERVAL TRAINING

THOMPSON, C., BAILEY, S.J., BLACKWELL, J.R., FULFORD, J., WYLIE, L.J., BLACK, M.I., KELLY, J., McDONAGH, S.T.J., CARTER, J., VANHATALO, A., JONES, A.M.

Sport and Health Sciences, NIHR Exeter Clinical Research Facility, University of Exeter, Heavitree Road, Exeter, UK and Gatorade Sports Science Institute, PepsiCo R&D, Barrington IL, USA

Short-term dietary nitrate supplementation may favourably impact the intrinsic properties of skeletal muscle. It is unclear whether longer periods of nitrate supplementation may more favourably alter the physiological response to exercise and improve exercise performance. Furthermore, the possible interaction of a high-nitrate dietary supplement, such as beetroot juice (BR), with the adaptations to exercise training is presently unknown. We therefore tested the hypothesis that chronic BR supplementation would augment skeletal muscle metabolic adaptations to high-intensity interval training (HIIT). Twenty-four men and 24 women completed a series of exercise tests before and following a 4 week period in which they were assigned to: 1) HIIT and no supplementation (HIIT); 2) HIIT and nitrate-depleted beetroot juice as a placebo (HIIT+PL); 3) HIIT and nitrate-rich beetroot juice (~13mmol nitrate/day; HIIT+BR); or 4) no training and nitrate-rich beetroot juice (NT+BR). During sub-maximal exercise, $\dot{V}O_2$ was reduced by HIIT+BR and NT+BR but not HIIT or HIIT+PL. During incremental exercise, $\dot{V}O_2$ peak was increased by HIIT and HIIT+BR but not HIIT+PL or NT+BR. Compared to pre-intervention, maximal citrate synthase activity was elevated in HIIT+BR only (Pre 15.9 ± 3.4 vs Post $18.1 \pm 2.0 \mu\text{mol}\cdot\text{g d.w.}^{-1}\cdot\text{min}^{-1}$; $P<0.05$). Similarly, muscle [glycogen] was higher (Pre 335 ± 119 vs Post $441 \pm 144 \text{ mmol}\cdot\text{kg d.w.}^{-1}$; $P<0.05$), muscle pH was greater (Pre 6.9 ± 0.3 vs Post 7.1 ± 0.2 ; $P<0.05$) and [lactate] was lower in muscle (Pre 53 ± 33 vs Post $33 \pm 26 \text{ mmol}\cdot\text{kg d.w.}^{-1}$; $P<0.05$) and blood (Pre 5.0 ± 0.8 vs Post $3.7 \pm 1.0 \text{ mM}$; $P<0.05$) at 3-min of severe-intensity exercise in HIIT+BR but not HIIT, HIIT+PL or NT+BR. However, the improvement in severe-intensity exercise performance was not different between training interventions. In conclusion, BR ingestion reduced the O₂ cost of moderate-intensity exercise and increased peak WR during incremental exercise whereas HIIT improved $\dot{V}O_2$ peak, peak WR, and severe-intensity exercise performance. Similar effects to HIIT alone and NT+BR were found when HIIT and BR were combined but, in addition, maximal CS activity was increased and muscle metabolic perturbation during severe-intensity exercise was reduced. These data indicate that the independent physiological stimuli provided by HIIT and BR may be additive. Dietary nitrate supplementation in the form of BR may potentiate muscle metabolic adaptations to HIIT.

AFTER EFFECTS OF A 3 WEEKS NO3 SUPPLEMENTATION ON ENDURANCE AND SPRINT PERFORMANCE

MAASSEN, N.1,2, FINKEL, A.1,2, JACOB, C.1, RÖHRICH, M.2, LÜTZOW, M.2, BLAU, L.2, HANFF, E.3, TSIKAS, D.3, MAASSEN, M.1,2

1 Leibniz University Hannover, 2 Medical School Hannover 3 Medical School Hannover

Introduction Most studies investigating the effects of NO₃ supplementation were performed during the supplementation period. The aim of the present study was to look for after effects of such a supplementation and answer the question: are there influences on the development of performance? Methods 17 subjects took part in the placebo-controlled double-blind study (Nitrate: 9; Placebo (NaCl) 8). Maximum power in a preceding incremental test was not significantly different between the groups (N: $4.83 \pm 0.9 \text{ Watt/kg}$, PLA: $4.85 \pm 0.6 \text{ Watt/kg}$). The subjects performed an intermittent training of high intensity (HIIT) on a cycle ergometer (Lode Excalibur) 3 times a week for 3 weeks (45x 30s at 100% - 10W and 30s of 10W, 45). The subjects supplemented either sodium-nitrate [8.5 mg/kg body weight/d] (N, n=9) or sodium-chloride [8.5 mg/kg body weight/d] (PLA n=8) daily. Besides the incremental test (IT) a double Wingate-Test (one minute break between both, (WT)) and an endurance test to exhaustion (ET) with 80% of maximum power reached in the incremental test were performed as pre- and post-tests. [NO₃] and [NO₂] were measured in the cubital venous plasma (GC-MS-Method, Tsikas et al. 2000). The post-tests were performed at least 2 days after the end of supplementation period, when [NO₃] and [NO₂] in plasma are supposed to have returned to normal values (Webb et al. 2008). Results [NO₃] and [NO₂] did not differ between the pre- tests and the tests performed 2 days after supplementation (S). At least 2 days after the supplementation period (S) in the first WT maximal power (+4.5%) and mean power (+4.2%) were increased in PLA ($p<0.05$ for both) whereas there was no significant difference in N. Both groups improved maximal (+9%) and mean power (+7%) in the second WT ($p<0.05$ for all) without any difference between the groups. However, the oxygen cost per Watt was significantly ($p<0.05$) reduced in N (-11.5%). During the ET (4 days after S) the $\dot{V}O_2$ was significantly lower. Even at exhaustion there was a 5% reduction in $\dot{V}O_2$ ($p<0.01$). In spite of that the endurance time was not significantly different. Maximum Power reached in the IT post-test was enhanced in both groups (+3.9% in PLA) and (+5.1% in N) being significant in N, only. Again, the increase in $\dot{V}O_2/\text{Watt}$ was lower in N ($p<0.05$). Conclusion A supplementation of NO₃ for 3 weeks elicits effects on performance lasting at least for 7 days. The persisting effects look similar to those expected when fast muscle fibers change to more oxidative fibers. M. MONTMORENCY CHERRY SUPPLEMENTATION ATTENUATES VASCULAR DYSFUNCTION INDUCED BY PROLONGED OCCLUSION

ABOO BAKKAR, Z., FULFORD, J., GATES, P.E., BOND, B., JONES, A.M., BOWTELL, J.L.

University of Exeter

Introduction Higher flavonoid intake is associated with reduced risk of cardiovascular related diseases, whilst both acute and chronic fruit flavonoid supplementation improve brachial artery flow-mediated dilatation (FMD), a nitric oxide dependent marker of endothelium dependent vasodilatation. Repeated cycles of ischaemia reperfusion injury (IRI) contribute to endothelial dysfunction. Therefore, we investigated whether chronic supplementation with Montmorency cherry (MC) attenuated the suppression of brachial artery FMD induced by prolonged occlusion. **Method** In a double-blind, placebo-controlled, crossover design, 10 physically inactive middle aged men (54.0 ± 4.6 ; 28.6 ± 4.9 kg.m $^{-2}$) consumed MC capsules (235mg.d $^{-1}$ anthocyanins) and placebo (PL) for 4 weeks in pseudo-random order separated by 4 weeks washout. Pre and post supplementation FMD responses were measured at baseline and 15, 30, and 45 min after a 20 min forearm occlusion to induce IR. Blood samples were obtained from the occluded arm at the beginning of the procedure and immediately, 2, 4, 15, 30 and 45 minutes after the 20-minutes occlusion for the measurement of nitric oxides metabolites. Baseline plasma samples before and after each supplementation block were analysed for interleukin 6 (IL-6) and C-reactive protein (CRP). Data were analysed by repeated measures ANOVA and presented as mean \pm SD. Results Prolonged occlusion resulted in significant reduction of FMD, 15 min post occlusion in both conditions (BL vs 15min; MC: $-57.9 \pm 17.1\%$; PL: $-48.1 \pm 23.8\%$, time effect: $P < 0.001$) and remained depressed after 45 min (BL vs 45 min MC: $-4.8 \pm 39.3\%$; PL: $-26.2 \pm 12.6\%$, time effect: $P = 0.035$). There was a tendency for greater recovery of FMD response with MC supplementation (condition x supplementation interaction: $P = 0.080$) after 45 min. Area under the curve for shear also decreased after prolonged occlusion ($P = 0.036$), and tended to recover better after MC supplementation (condition x time interaction: $P = 0.094$). Plasma nitrate concentration decreased significantly in response to the prolonged occlusion (main time effect: $P < 0.001$), with tendency for higher plasma nitrate concentration after MC supplementation (condition x supplement x time interaction: $P = 0.076$) compared to placebo. Neither plasma CRP nor IL-6 concentrations were affected by cherry or placebo supplementation. **Conclusion** In conclusion, prolonged forearm occlusion impaired FMD for at least 45 min, and MC supplementation tended to improve FMD recovery in parallel with higher plasma nitrate concentration. These effects may contribute to the vascular health benefits associated with flavonoid intake. Contact zba201@exeter.ac.uk

SOLUBLE MILK PROTEINS OR WHEY SUPPLEMENTATION COMBINED TO ELECTROSTIMULATION TRAINING: WHAT EFFECTS ON POWER PRODUCTION AND RECOVERY CAPACITIES ?

MARTIN, V.1, GARCIA-VICENCIO, S.1, MASGRAU, A.1, BRASY, J.2, BUCAS, M.2, LECOEUR, A.2, LE RUYET, P.2, RATEL, S.1

(1) Université Blaise Pascal; (2) Lactalis

Introduction Electrostimulation training (ES) has the potential to increase muscle power. However, this training modality exposes the recruited motor units to a large stress. This sometimes translates into recovery and training adaptation issues. However, it has been demonstrated in humans that a supplementation of soluble milk proteins (SMP) could reduce fatigability after a strength training session and during the training period. Therefore, SMP could promote recovery and adaptations to ES training, compared to other milk proteins. The purpose of this study was to verify this hypothesis. **Methods** This pilot, randomized and double-blinded study involved 36 moderately active young men (21.6 ± 3.2 y). They were allocated into 3 groups supplemented 5d/week, either with 15g of SMP or whey proteins (WH), or with a placebo (PLA). All groups underwent a 12-week ES training program of the knee extensor muscles. During the last 6 weeks, ES training was combined with sprint and plyometrics training. Maximal power (Pmax), serum creatine kinase activity (CK) and muscle soreness (DOMS) were evaluated before, immediately after and 30', 60', 24h and 48h after the first (S1), fourth (S4) and last ES training session (S24). Evoked contractile properties (twitch amplitude; Pt) and the maximal voluntary activation level (VA) were measured before training (T0), and after 6 (T1) and 12 weeks of training (T2). Results DOMS and CK did not differ between groups. On average CK was higher at S4 compared to S1 and S24 ($P < 0.001$). Furthermore, DOMS decreased between S1 and S24 ($P < 0.001$). However, Pmax increased in the SMP and WH groups between S1 and S24 (+12.5%, $P < 0.001$ & +13.9%, $P < 0.01$, respectively). No change was observed in PLA. At S4, 30' after the training session the SMP group displayed a faster Pmax recovery compared to WH (569 vs. 474 W; $P < 0.05$). At S24, the SMP had fully recovered 30' after the training session. This was not the case for WH and PLA. During the training program, the evolution of the NA did not differ between groups. However, the modification of Pt differed between groups: Pt increased between T0 et T2 in the SMP group ($+16.4 \pm 8.9\%$; $P < 0.001$), was not significantly modified in WH, and decreased between T1 and T2 in PLA ($-9.3 \pm 4.9\%$; $P < 0.05$). **Conclusion** These results suggest that SMP have the potential to promote the short term recovery of maximal power after an ES training session compared to WH. This improved recovery is associated with a better adaptation to training, which translates into improved contractile properties in SMP, but not in WH. Therefore, as compared to WH, SMP could be more efficient to improve muscle performance after a training program.

DIET QUALITY AND MACRONUTRIENT INTAKE DURING A PRECOMPETITIVE TRAINING CAMP IN MALE AND FEMALE SPANISH WHEELCHAIR BASKETBALL PLAYERS

GRAMS, L.1, FERRO, A.1, VILLACIEROS, J.1, GARRIDO, G.1

1: Faculty of Physical Activity and Sports Science-INEF Technical University of Madrid /Spain

Do not insert authors here **Introduction:** Wheelchair basketball has evolved into a high performance sport over the last several years and small variations in performance can determine the difference between winning and losing (Perret, 2015). In addition to physical fitness, an optimized diet is important to enhance performance and recovery. In fact, there are only a few studies available describing nutrition practice in wheelchair basketball (Goosey-Tolfrey and Crosland, 2010). Therefore, an adequate macro- and micronutrient intake may influence this difference. **Methods:** During a five-day precompetitive training camp the Spanish male and female National Teams of wheelchair basketball have been evaluated regarding their nutritional intake via a nutritional protocol and body composition by anthropometric assessment (ISAK). The Software Dial AlceAE was used for the analysis of diet composition and quality. **Results:** Twelve male (age 29.4 ± 6.8 years; height 180.7 ± 5.1 cm; weight 78.2 ± 16.7 kg) and ten female (age 22.1 ± 6.3 years; height 154.3 ± 18.5 cm; 57.9 ± 16.2 kg) wheelchair basketball players took part in the study. Analysis revealed a total energy intake of 3194 ± 504 kcal/day and 1916 ± 404 kcal/day ($p < 0.001$; $d = 3.03$) or 42.3 ± 10.3 kcal/kg and 36.2 ± 15.3 kcal/kg ($p = 0.277$), for the male and female athletes, respectively. Carbohydrate intake was 3.8 ± 1.2 g/kg for males and 2.9 ± 1.4 g/kg for females ($p = 0.109$) and protein intake was 2.0 ± 0.5 g/kg 1.5 ± 0.6 g/kg ($p = 0.047$; $d = 0.99$) respectively. When taking the quality index -out of 10- into account, the food groups fruits (males 4.7 ± 3 ;

females 3.2 ± 2.8 ; $p=0.274$) and vegetables (males 3.7 ± 1.2 ; females 1.4 ± 0.5 ; $p<0.001$; $d=2.51$) were very low resulting in a high proportion of fat (males $43.6 \pm 4.9\%$; females $50.1 \pm 4.0\%$; $p=0.003$; $d=1.59$). Anthropometrics analysis showed a sum of all eight skinfolds thickness of 135.9 ± 51.3 mm for males and 153.9 ± 62.1 mm for females ($p=0.466$). Discussion: Male wheelchair athletes showed slightly better results than female athletes regarding fruit and vegetable intake, which resulted in a higher overall diet quality. Nevertheless, it has to be highlighted, that except for breakfast, the main meals lunch and dinner were served as plates and not as a buffet. Previous studies showed that diet variety is very important to reach adequate macro- and micronutrient intake (Grams et al., 2016). Further research is needed to improve diet and body composition in these athletes. References: 1. Perret C. (2015). Disabil Rehabil, 27:1-9. 2. Goosey-Tolfrey VL, Crosland J. (2010). METABOREFLEX AND PERFORMANCE IN ELITE FEMALE SOCCER: EFFECTS OF INSPIRATORY MUSCLE TRAINING

ARCHIZA, B., ANDAKU, D.K., CARUSO, F.R., RICCI, P.A., BONJORNO JR, J.C., OLIVEIRA, C.R., PHILLIPS, S.A., ARENA, R., BORGHI-SILVA, A.

Federal University of São Carlos

Introduction Inspiratory muscle training (IMT) is an established way to improve strength (S) and endurance (E) of inspiratory muscles. It has been extensively studied and used as an important tool in sports performance, mainly for those aerobic in nature. The objectives of this study are to test the effects on metaboreflex and exercise performance in a professional athlete cohort. Methods Eighteen professional female soccer players were recruited and underwent a cardiopulmonary exercise test. Subjects were randomized to placebo (PG) and IMT (IMTG) groups. Subsequently, they underwent tests of lung function, S and E of inspiratory muscles, constant high-load exercise testing (CLET) and repeated-shuttle-sprint ability test (RSSA). Near-infrared spectroscopy assessed oxygenation ([oxyHb] and [Hb]) of respiratory (intercostals) and peripheral (vastus lateralis) muscles during CLET and blood samples were taken to analyze lactate concentration ([L]). After 6-weeks of IMT [30 inspiratory efforts, twice/day, 5 days/week, IMTG training at 50% of maximal inspiratory pressure with load adjustments every week], subjects were reevaluated. Results There were significant improvements observed in the IMTG following IMT: 1) gain of inspiratory muscles S ($19.45 \pm 10.91\%$) and E ($53.06 \pm 32.51\%$); 2) greater exercise tolerance ($P<0.05$) and reduced [L] over time ($P<0.05$) in CLET; 3) [oxyHb] of intercostals muscles was higher (from -8.66 ± 4.96 to -1.94 ± 8.50 umol/cm) while [Hb] was also higher in the vastus lateralis (from 2.21 ± 5.60 to 5.56 ± 7.21 umol/cm), and; 4) soccer performance inferred by RSSA was better after IMT ($P<0.05$). Discussion Recent evidence shows that IMT could affect lactate recovery, indicating that respiratory muscles are capable of lactate clearance, reducing [H+] and metabolites (Brown et al., 2009). This could explain the increased exercise tolerance and improved athletic performance (Nicks et al. 2009). Likewise, blunted metaboreflex responses were observed post-IMT only in the IMTG, indicating an increase of [oxyHb] and [Hb] in respiratory and peripheral muscles, respectively, in accordance with previous study (Witt et al., 2007). We conclude that IMT is an important and effective strategy to enhance exercise performance in professional women soccer players. References Brown PI, Sharpe GR, Johnson MA. THE EFFECT OF AGE ON PULMONARY AND MUSCLE OXYGENATION KINETICS FOLLOWING HIGH-INTENSITY INTERVAL EXERCISE

BORGES, N.R., REABURN, P.R., DOERING, T.M., ARGUS, C.K., DRILLER, M.W.

Central Queensland University

Introduction Physiological measures of pulmonary and muscle oxygenation follow an exponential trends following exercise until reaching baseline values. A steeper exponential trend suggests faster post-exercise recovery. To date, no study has investigated the effect of age on off-transient pulmonary and muscle oxygenation kinetics following high-intensity interval exercise (HIE) typical of training undertaken by both competitive endurance and sprint cyclists. Therefore, this study examined the effect of age on the off-transient pulmonary and muscle oxygenation kinetics in well-trained masters and young cyclists following HIE. Methods Pulmonary (VO₂) and muscle oxygenation (Total Oxygenation Index (TOI) and change in deoxyhemoglobin concentration ($\Delta[Hb]$)) were monitored continuously in well-trained masters ($n = 9$, age: 55.6 ± 5.0 yr) and young ($n = 8$, age: 25.9 ± 3.0 yr) cyclists during HIE and recovery. The HIE consisted of 6×30 second intervals at 175% maximal aerobic power with 4.5 minutes rest between intervals. Following the HIE, 20 minutes of passive supine rest was undertaken. The off-transient responses of VO₂, TOI and $\Delta[Hb]$ from the cessation of the HIE were then modelled using a mono-exponential function. Results The time constant (τ) of the VO₂ response (τ_{VO_2}) was significantly longer in the masters (mean \pm SD; 217.49 ± 44.43 s) compared to young (169.69 ± 35.73 s) cyclists ($P = 0.029$). The amplitude of the VO₂ response was also lower in masters ($d = 0.69$, moderate), although not significant ($P = 0.18$). A trend for a slowed τ_{TOI} was found in the masters cyclists, however this was not found to be significant ($P = 0.40$, $d = 0.42$, small). Significant correlations were observed between τ_{TOI} and both τ_{VO_2} ($r = 0.49$, $P = 0.049$) and $\tau_{[Hb]}$ ($r = 0.75$, $P < 0.001$), and a non-significant moderate relationship was found between age and τ_{VO_2} ($r = 0.48$, $P = 0.05$). Discussion: The significantly slowed τ_{VO_2} suggests that masters athletes exhibit longer time for metabolic recovery following HIE. Additionally, although no significant age-related differences for muscle re-oxygenation kinetics where observed a trend for a slower τ_{TOI} during the recovery phase was found. The slowed pulmonary and muscle oxygenation kinetics may have a negative effect on repeat sprint performance in masters athletes and greater recovery periods between exercise bouts may be necessary to maintain power output. PHYSICAL ACTIVITY IS ASSOCIATED WITH ALLERGIC DISEASE, BUT NOT ALLERGIC SYMPTOMS OR SENSITIZATION, IN ADOLESCENTS

SMITH, M.P., BERDEL, D., BAUER, C.P., KOLETZKO, S., NOWAK, D., SCHULZ, H., HEINRICH, J.

Ludwig Maximilians University; Helmholtz Zentrum München; Marien-Hospital Wesel; Comprehensive Pneumology Center Munich; Technical University Munich

Introduction: Allergic sensitization, including asthma and rhinitis, is often associated with decreased physical activity (PA.) However, it is not clear whether allergy discourages PA, PA prevents allergy, or both. We examine the relationships between moderate and vigorous PA (MPA, VPA), participation in sport, and respiratory allergy in adolescents, in order to determine which conditions, if any, are associated with decreased PA in this population. **Methods:** 1168 Germans (45% male, age 15.5 ± 0.5 years) completed 7-day accelerometry, activity diary, standardized questionnaires, physical examination and IgE RAST for aero-allergens. Measurements of PA included daily minutes of MPA and VPA as well as participation in sports (such as football.) In each sex, PA (any sport participation, MPA, or VPA) was modeled as function of asthma, rhinitis, aero-sensitization, or current symptoms of asthma (wheezing) or rhinitis (nose/eye itching), corrected for age, height, location, and parental education. **Results:** Despite high prevalence of symptoms (wheeze, 6% of children; eye/nose symptoms, 11%) over $\frac{3}{4}$ of our subjects had sport during accelerometry. 8% had asthma, 11% had rhinitis, and 45% were aero-allergen sensitized. Asthmatic girls more often wheezed (68 vs. 43%) or were untreated (22% vs. 6%) than asthmatic boys. Nevertheless, allergic diagnoses were associated with low PA only in boys. In corrected models, boys with asthma had 33% less VPA ($p<0.01$) and 14% less MPA ($p=0.03$) per day, and those with rhinitis had 14% less MPA ($p=0.03$.) There was no effect for sensitization, and allergic children were as likely as lung-healthy controls to participate in sport. Results were consistent when analysis was restricted to normal-weight children or those with negative bronchial-challenge tests, and neither PA nor sport participation was associated with respiratory symptoms in either sex. **Conclusion:** Boys with asthma or rhinitis were less physically active than lung-healthy controls. The relationship was not mediated by sport participation or explicable by current high body weight or residual symptoms, and was consistent with known immunomodulatory effects of PA. We suggest that PA may help prevent and mitigate immune dysfunction, adding urgency to the need for greater access to sport.

REFERENCE VALUES OF PHYSICAL FITNESS IN ANDALUSIAN FIBROMYALGIA PATIENTS: THE AL-ÁNDALUS PROJECT.

ÁLVAREZ-GALLARDO, I.C., CARBONELL-BAEZA, A., SEGURA-JIMÉNEZ, V., SORIANO-MALDONADO, A., INTEMANN, T., APARI-CIO, V.A., ESTÉVEZ-LÓPEZ, F., CAMILETTI-MOIRÓN, D., HERRADOR-COLMENERO, M., BORGES-COSIC, M.

University of Granada (Spain)

Delgado-Fernández, M., Ortega, F.B. Introduction Physical fitness is an important indicator of health in fibromyalgia (Aparicio et al., 2015). Therefore, it is essential to have reference values on the different fitness components, which will allow better interpretation of the results of fitness assessment in this population. The aims of this study were (1) to report age-specific physical fitness levels in people with fibromyalgia of a representative sample from Andalusia (southern Spain); and (2) to compare the fitness levels of people with fibromyalgia with non-fibromyalgia controls. **Methods** This cross-sectional study included 489 (21 men) people with fibromyalgia and 416 (55 men) controls. The sample of people with fibromyalgia was geographically representative from Andalusia. Physical fitness was assessed with the Senior Fitness Test battery (chair sit-and-reach, back scratch, 30-s chair stand, arm curl, 8-foot up-and-go and 6-min walk tests) plus the hand-grip strength test. We applied the Generalized Additive Model for Location, Scale and Shape (GAMLSS) to calculate percentile curves for women and fitted mean curves using a linear regression for men. Sex and group (fibromyalgia vs. control) differences in physical fitness were tested through two-way ANOVA. **Results** The present study provided reference values for all the physical fitness components in women and men with fibromyalgia. People with fibromyalgia showed worse performance than controls in all the fitness tests evaluated ($p<0.001$). **Discussion** Physical fitness levels observed in fibromyalgia are very low in comparison with age-matched healthy controls. The reference values provided in the present study are useful to correctly interpret physical fitness assessments and might help health care providers to identify individuals at high risk of losing physical independence, as well as to design personalized intervention programs. EPICARDIAL ADIPOSE TISSUE, EXERCISE AND CARDIOVASCULAR DISEASE IN DIABETES

CHRISTENSEN, R.1, SCHOLTEN, B.2, ROSENMEIER, J.3, HANSEN, C.2, ELLINGSGAARD, H.1, REINHARD, H.2, PARVING, H.4, PEDERSEN, B.1, JØRGENSEN, M.2, JACOBSEN, P.4, ROSSING, P.2

(1,4) Rigshospitalet, DK, (2)Steno Diabetes Center, DK, (3) Bispebjerg Univ. Hospital, DK

Background: Epicardial adipose tissue (EAT) is the visceral fat of the heart. Patients with type 2 diabetes (T2D) have more and inflamed EAT compared to non-diabetic individuals, and EAT excretes substances that may provoke coronary atherosclerosis (1,2). The role of EAT in cardiovascular disease (CVD) and the impact of weekly exercise on EAT and CVD in diabetic patients was investigated in this study. **Methods:** This was a prospective study including 200 T2D patients without known CVD. EAT was measured from baseline echocardiography (3). Physical activity was self-reported as hours of exercise per week. Coronary artery calcium (CAC) and markers of low-grade inflammation (IL-1 β , IL-6, IL-8, TNF α and hsCRP) were measured at baseline. Follow-up was performed after (median) 6.1 years with no lost to follow-up. Primary endpoint was the composite of incident CVD and all-cause mortality. Data were expressed as mean \pm SD. Exercise and EAT were investigated as continuous variables, and EAT was split in quartiles (the highest vs. the three lowest). Time-to-event data were analysed by Kaplan-Meier survival plots and Cox regression. Adjustment was performed for risk factors of CVD (sex, age, LDL-cholesterol, smoking, HbA1C, and systolic blood pressure). **Results:** 152 (76%) were men, age average of 59 ± 9 years, and known diabetes duration of 13 ± 7 years. Median weekly exercise (IQR) was 3.27 (0,3.5) hours. Mean EAT was 3.3 ± 1.7 mm and EAT in the highest quartile was 5.6 ± 1.2 mm vs. 2.4 ± 0.9 mm EAT in the three lower quartile groups. During the follow-up period 66 patients had experienced a CVD event or died. Patients with elevated EAT had an increased risk of the composite endpoint when compared with patients with normal EAT (HR 1.8 (95% CI 1.0-3.2), $p=0.047$). Weekly exercise duration was negatively associated with the composite endpoint, even after adjusting for CVD risk factors (HR 0.84 (95% CI 0.7-0.9)). EAT and exercise tended to be negatively correlated ($p=0.07$) and EAT was positively correlated to CAC ($p=0.032$) and TNF α ($p=0.047$). **Discussion:** In a prospective study with 200 T2D patients without known CVD, we found that elevated EAT and low weekly exercise duration were associated with our composite endpoint of CVD and all-cause mortality. Our novel data suggest further research exploring the role of EAT and physical activity in T2D and cardiovascular complications. References: (1) Eiras et al. FAT OXIDATION CAPACITY AND ITS POSSIBLE COUPLING TO WEIGHT LOSS MAINTENANCE

HUSTED, K., DANDANELL, S., VIGELSØ, A., DELA, F., HELGE, J.W.

Institute of biomedical science

Introduction: Current perception is that the majority of participants after intensive weight loss interventions regain all of their weight within 5 years. Dissent regarding fat oxidation impairment in obese subjects makes it clinically relevant to study the possible adaptations in maximal fat oxidation (MFO) after a persistent long-term weight loss and its impact on weight loss maintenance. The aim of this study was to investigate if MFO differs in relation to size of weight loss, including cellular mechanisms that contribute to MFO in skeletal muscle. The hypothesis was that weight loss maintenance is positively correlated to MFO. **Methods:** 78 former (>4y) participants in a 12 wks. intensive Lifestyle Intervention (LI) were recruited. The LI program consists of hypo caloric diet, structured physical activity and health education. Participants were stratified into 3 groups based on the size of weight loss at follow up; High Maintenance (HM >10%) Moderate Maintenance (MM 0-10%) and No Maintenance (NM <0%). A muscle biopsy from m. vastus lateralis was obtained and a graded cycle ergometer exercise test determines MFO and the intensity at which this occur (Fatmax). Subsequently a VO₂max test was performed. HAD and CS activity were examined fluorometrically and CD36 and FABPpm expression using western blot technique. One-way Anova was used to test for the between group differences and the level of significance was set at 0.05. **Results:** There were no differences in BMI before or BMI and weight loss at the end of LI. The weight loss compared to before LI was (22±1, 5±1 and -9±1%) in HM, MM and NM, respectively. MFO was higher ($P<0.05$) in HM and NM compared to MM (0.5±0.1; 0.5±0.1; 0.4±0.2 g/min), respectively. VO₂max was higher ($P<0.05$) in HM compared to MM and NM (32±1; 25.8±1; 21.3±1 ml/min/kg). HAD (123±5; 105.6±6; 97±4 umol/g/min) and CS activity (155±6; 130±8; 113±5 umol/g/min) were higher ($P<0.05$) in HM compared to MM and NM, respectively. FABPpm expression was higher ($P<0.05$) in HM compared to MM and NO (36 and 40%, respectively. Finally CD36 expression was higher (16%, $P<0.05$) in HM compared to NM. **Discussion:** This study demonstrates that when a clinically significant (>10%) weight loss is maintained over a longer period, MFO is increased in parallel with higher VO₂max, mitochondrial activity and FA transport capacity. Interestingly the high MFO in NM, despite low CS, HAD, FABPpm and CD36, indicates the presence of a 'healthy and unhealthy' MFO, where MFO in NM most likely is driven by high availability of IMTG and/or plasma FA. This may explain the U-shaped relationship between weight loss and MFO and also VO₂max and MFO. Contact: karinalu@sund.ku.dk

Oral presentations**OP-BN01 Biomechanics****COMPARISON OF DIFFERENT MARKER SETS FOR MARKER TRAJECTORY BASED CLASSIFICATION OF SIMULATED GAIT IMPAIRMENTS**

CHRISTIAN, J.1, HEBENSTREIT, F.2, ESKOFIER, B.M.2, SCHWAMEDER, H.1

1: University of Salzburg (Austria), 2: University of Erlangen-Nuernberg (Germany)

Introduction 3D marker trajectories can be used straightforwardly as input for gait classification without prior mechanical modelling (Eskofier et al., 2013). Such an approach is computationally efficient and independent of specific mechanical model assumptions. This study investigated how the choice of the marker set affects the performance of selected algorithms for classifying impaired gait patterns. A full body marker set and three reduced marker sets were tested. To enable full control of the location and extent of the impairment it was simulated by means of artificially induced restriction of motion in the knee joint. The reduced marker sets were particularly chosen to be distributed with different spreads around the restricted joint. Method 3D kinematics of 29 healthy males were recorded for normal and simulated impaired walking. Latter was realized by restricting knee extension of one leg to approximately 170° by means of an orthosis. The data analysis was conducted with four marker sets of different sizes (number of markers): full body (37), lower body (16), restricted leg only (8) and hip, knee and ankle of the restricted leg (3). Principal component analysis was used for dimensionality reduction. Linear Support Vector Machine (SVM), naïve Bayes (NB), AdaBoost (AB) and Random Forest (RF) were trained to classify normal and simulated impaired walking. Cross validation was used to check for accuracy. Mean posterior accuracy and 95% credible intervals were estimated to compare marker sets and classifiers (Brodersen et al., 2010). Results The accuracies of all classifiers were around chance level with the full body marker set and tended to increase with a lower number of markers. RF, AB and SVM classified significantly above chance level with the smallest marker set. Accuracies of the classifiers did not differ significantly within each marker set, whereas SVM tended to perform best with a mean posterior accuracy of 77% on the smallest marker set. **Discussion** Selecting a reduced marker set can be beneficial independent of the type of classifier. This is remarkable as the smaller marker sets are subsets of the larger sets. The simulations were well controlled and thus allowed logical considerations for selecting a small marker set that definitely contains discriminative information. Reducing the number of less informative dimensions might facilitate classification. Future work should address developing a heuristic data driven procedure for choosing a proper marker subset without prior knowledge about the impairment in order to enhance practical applications. LOWER LIMB MUSCLE FORCES DURING SLOPED WALKING AT DIFFERENT INCLINATIONS

ALEXANDER, N., SCHWAMEDER, H.

University of Salzburg

Introduction Lower limb joint forces are increased during sloped walking compared to level walking (Alexander & Schwameder, 2016). Furthermore, muscle forces were previously shown to be major contributors to lower limb joint forces (Correa et al., 2010). Therefore, the aim of this study was to analyse lower limb muscle forces during sloped walking at different inclinations in order to understand the underlying mechanisms of the increased joint forces and to provide evidence based training program recommendations. **Methods** Male participants (n=18, 27±5 y, 1.80±0.05 m, 75±8 kg) walked at a pre-set speed of 1.1 m/s on a ramp at the inclinations of 0°, ±6°, ±12° and ±18°. Kinematic data were captured with a motion analysis system (Vicon, 250 Hz) and kinetic data were recorded with two force plates (AMTI, 1000 Hz) imbedded into the ramp. A musculoskeletal model (AnyBody) previously validated for sloped walking (Alexander &

Schwameder, 2015) was used to compute the forces of 18 lower limb muscles. Changes in mean muscle forces were analysed using the Friedman test. In cases of significance, Wilcoxon tests with Bonferroni correction were used as post-hoc. Results All lower limb muscle forces (except gluteus medius) were significantly altered during sloped compared to level walking. Amongst others, downhill walking increased quadriceps (>140%) and decreased hamstrings (<22%) and gastrocnemii (<22%) muscle forces. Uphill walking increased mean quadriceps (>96%), hamstrings (>36%) and gastrocnemii (>12%) muscle forces. Joint-muscle-force waveforms provided information on possible muscle contributions to joint compression forces. The most important muscles were: gluteus medius for hip forces, quadriceps and gastrocnemii for tibiofemoral forces, quadriceps for patellofemoral forces and triceps surae for ankle forces. Discussion Muscle forces during level walking were consistent with data presented previously (Correa et al., 2010), but did not entirely support results of a predictive simulation of uphill walking (Dorn et al., 2015). In agreement with Correa et al. (2010), gluteus medialis provided the greatest contribution to the compressive hip force. The crouched posture during sloped walking (Dorn et al., 2015) is most likely responsible for the increased quadriceps force (Steele et al., 2012) and therefore the increased tibiofemoral and patellofemoral joint loadings. The study provided important information on muscle forces during sloped walking as a useful basis for the development rehabilitation and training procedures. MUSCLE STIFFNESS IS REDUCED FOLLOWING A SINGLE STATIC STRETCHING EXERCISE BUT NOT FOLLOWING SIX WEEKS OF STATIC STRECHTING TRAINING

KONRAD, A.1, STAFYLIDIS, S.2, TILP, M.1

KFU Graz

1: KFU Graz (Austria) 2: AU Thessaloniki (Greece) Introduction There is evidence that a single static stretching (SS) exercise decreases muscle stiffness (Kay et al. 2015). However, it is not yet well understood if this structural change of a single SS causes a chronic adaptation following several weeks of repeated SS. Therefore, the purpose of this study was to investigate the effects of a single SS exercise (4x30sec) and six-week SS training (5/week for 4x30sec) on the muscle-tendon unit (MTU) of the gastrocnemius medialis (GM). We hypothesized a gain in range of motion (RoM) following the single SS exercise and the SS training for six weeks. Besides a decrease in muscle stiffness following a single SS training, we expected also an adaptation of the muscle tissue following SS for six weeks (Kato 2009). Methods Forty-six healthy male (23.2±2.7years, 179.4±5.7cm, 75.6±6.8kg) and 27 healthy female (23.5±3.7years, 169.8±4.6cm, 61.3±5.3kg) physically active subjects participated in the study. They were randomly assigned to a SS group (n=25) and control groups for the single SS (n=24) and the six week SS (n=24), respectively. Before and after the single SS exercise and the six-week SS intervention, the RoM, passive resistive torque (PRT), maximum voluntary contraction (MVC), and several parameters of the muscle and tendon structure (muscle stiffness, tendon stiffness...) of the GM were determined with a dynamometer and ultrasound. Effects of the stretching interventions were tested with paired t-tests. Results There was an increase in RoM following the single SS exercise (1.2±2.6°; P=0.04) and the six-week SS training (5.4±5.0°; P<0.01). Following the single stretching exercise the yield in RoM was accompanied by a decrease in muscle stiffness (1.1±2.1N/mm; P=0.02), joint stiffness (0.1±0.1Nm²; P<0.01), and PRT (3.0±3.9Nm; P<0.01). Besides RoM, no other significant changes were observed following the six-week SS training. Moreover, no significant changes of the MVC, tendon stiffness, fascicle length, and pennation angle were found in single SS or SS for six weeks. No significant difference in any parameter was detected in the control groups. Discussion The findings of our study indicate that altered muscle tissue properties return to the initial state following a single SS (Mizuno et al. 2013). Despite an increase of RoM no structural adaptation of the MTU due to repeated SS for six weeks was observed. It seems probable that RoM changes are due to an increased stretch tolerance (Magnusson et al. 1996). References Kato E. ECSS BOA 2009:194-195. Kay AD, Husbands-Beasley J, Blazevich A. TENDON SIZE AND STIFFNESS: INFLUENCE OF SHORT-TERM AND CHRONIC STRENGTH TRAINING

MASSEY, G.J., BALSHAW, T.G., MADEN-WILKINSON, T.M., FOLLAND, J.P.

Loughborough University

Introduction Tendon stiffness increases following short-term (3 months) strength training with sustained high-loads, with some equivocal data for tendon hypertrophy. The potential for tendons to adapt to strength training, especially after several years of chronic exposure, remains largely unexplored. This study compared patellar tendon (PT) size and mechanical properties (stiffness, Young's modulus) between untrained controls, short-term strength trained (post-12 weeks training) and chronic-strength trained (>3 years of systematic training) groups. Methods Following familiarisation, maximal voluntary torque (MVT) and tendon stiffness were determined in duplicate measurement sessions. A control group (CON) comprised n=54 untrained males. A short-term strength group (SST, n=15 males) was measured post 12-weeks isometric knee extension strength training (3 x wk, 40 reps of 3-s at 75% MVT). A chronic strength-trained (CST) group comprised n=16 males with 4.0±0.8 (mean ± SD) years systematic heavy-resistance training experience (~3 x wk of quadriceps sessions). Simultaneous force and ultrasound recordings of PT elongation during constant loading-rate ramp contractions were used to derive PT stiffness at a common tendon force level. Tendon stress was calculated and Young's modulus estimated over a common stress range. Muscle volume and mean tendon cross-sectional area were measured from contiguous axial magnetic resonance images (5 and 2 mm). Univariate ANOVA was followed by post-hoc least-significant difference tests (with Holm-Bonferroni correction) between specific groups. Results MVT differed between all three groups (CST 394±68 vs SST 293±47 vs CON 245±42 Nm; All P≤0.001). CST quadriceps volume (2870±311 cm³) was much larger than both SST and CON (1967±316 and 1837±257 cm³; both P<0.001) though SST and CON muscle volumes were not statistically different (7%; P=0.113). PT stiffness was greater for SST (3279±536 N.mm, P=0.001, +23%) and CST (3076±578 N.mm, P=0.024, +15%) than CON (2664±491 N.mm), though similar between SST and CST (P=0.296). Likewise PT Young's modulus of SST/CST was greater than CON (+19/22%, P=0.009/P=0.004), with no difference in modulus between SST and CST (1.45±0.28 vs 1.49±0.25 GPa, P=0.734). There was no group effect for tendon cross-sectional area (ANOVA P=0.201). Conclusion Our findings indicate that despite substantial differences in maximal strength (+35%) and muscle volume (+46%), ~4 years of chronic strength training does not further increase tendon stiffness and modulus than occurs after 12 weeks of strength training. There was no evidence for tendon hypertrophy after strength training in this study.

LOAD SPECIFIC PATELLAR AND ACHILLES TENDON ADAPTATION: STRUCTURAL INTEGRITY OR FUNCTION?

WIESINGER, H.P.1, RIEDER, F.1, KÖSTERS, A.1, MÜLLER, E.1, SEYNNES, O.R.2

Introduction Tendon viscoelastic properties enable, *inter alia*, reducing the metabolic cost of locomotion (Lichtwark et al. 2007), enhancing muscle power production (Alexander & Bennet-Clark 1977) or preventing peak load injuries (Roberts & Azizi 2010). While the dual requirement of being strong but functionally adequate seem to be met by inherent repair and remodelling processes, current knowledge on tendon adaptations is largely fragmented into studies yielding partial information. This study aimed to determine whether distinct sets of tendon properties are seen in athletes engaged in sports with contrasting requirements for tendon function and structural integrity. Methods Thirty-nine male adults (27.3 ± 5.7 yrs) divided in four groups (elite ski jumpers, endurance runners and water polo players, and controls) were tested. From the original data set by combining ultrasonography, dynamometry, electromyography and 2D motion analysis, the following variables are presented: patellar (PT) and Achilles tendon (AT) stiffness, cross-sectional area normalized to body mass (nCSA), hysteresis and recovered strain energy. Results Tendon nCSA was smaller in water polo players than in other athletes (AT and PT; -24 to -28%) or controls (PT only; -9%). In runners (PT only; +26%) and ski jumpers (PT and AT; +21% and +13%, respectively), nCSA was larger than in controls. However, tendon stiffness only differed in ski jumpers, compared to controls (PT and AT; +11% and +27%, respectively) and water polo players (AT only; +23%). Hysteresis values were lower in the PT of ski jumper (-33%) and runner (-30%) compared to controls. The recovered strain energy was greater in ski jumpers compared to water polo players and controls (PT +55% and +52% and AT +32% and +36%, respectively) and to runners (PT only; +40%). Discussion Tendon strength or fatigue quality requirements seem to be preserved by adjustments of tendon size. However, uncoupled morphological and mechanical properties indicate that functional requirements may also influence tendon adaptations. The ability to conserve mechanical energy does not seem particularly confined to individuals subjected to a high volume of running training. Similar group differences in properties of PT and AT suggest that adaptive mechanisms may override their functional specificity. References 1. Alexander R McN & Bennet-Clark H C. EFFECTS OF FASCICLE LENGTHENING VELOCITY ON RADIAL AND LONGITUDINAL VASTUS LATERALIS MUSCLE GROWTH AFTER ECCENTRIC EXERCISE

MARZILGER, R.1, BOHM, S.1, LEGERLOTZ, K.1, SCHROLL, A.1, ARAMPATZIS, A.1

1: Humboldt-Universität zu Berlin (Berlin, Germany)

Introduction There is evidence that eccentric loading affects the longitudinal muscle growth and that the magnitude of the lengthening velocity of the fibers and the fiber length at which the eccentric load is applied are important influential factors (Butterfield and Herzog, 2006; Sharifnezhad et al., 2014). Recent findings of our group (Sharifnezhad et al., 2014) indicated fascicle lengthening velocity-specific effects on the radial and longitudinal muscle growth. Hence the purpose of this study was to investigate the effects of the lengthening velocity during eccentric exercises on radial and longitudinal growth of the vastus lateralis muscle (VL). We hypothesized a lengthening velocity-dependent radial and longitudinal muscle growth with lower velocities favoring radial hypertrophy and higher velocities facilitating longitudinal muscle growth. Methods We applied four different eccentric exercise protocols for the knee extensors (33 sessions, 3 times per week, 5 sets per training day) varying the angular velocity (i.e. 45, 120, 210 and 300°/s) in two experimental groups (both $n=13$, one protocol on each leg). The total eccentric loading volume was similar in all protocols. A control group ($n=12$, no training) was also included in the experimental design. Before and after the training we examined the maximal anatomical cross-sectional area (ACSA), fascicle length (FL) and pennation angle (PA) of the VL as well as the moment-angle relationship of the knee extensors using magnetic resonance imaging, ultrasonography and dynamometry. As statistics we performed a one way ANOVA for repeated measures ($\alpha=0.05$). Results According to preliminary results from 8 participants of each exercise protocol, the FL increased significantly ($p<0.05$) from 128.4 ± 17 mm to 137 ± 15.3 mm (45°/s protocol; P45), 132.4 ± 19.2 mm to 137.8 ± 21 mm (P120), 130.5 ± 15.2 mm to 135.4 ± 14.8 mm (P210) and 131.3 ± 17.8 mm to 139.2 ± 17.3 mm (P300) respectively. The PA did not change in any exercise protocol. The mean increase in maximal knee extension moment for all protocols was $15 \pm 12\%$ ($p<0.05$). The maximal ACSA increased significantly ($p<0.05$) for all protocols from 35.8 ± 2.2 cm 2 to 37 ± 1.5 cm 2 (P45), 33.5 ± 4.5 cm 2 to 35.7 ± 4.4 cm 2 (P120), 34.3 ± 4.4 cm 2 to 36.3 ± 4.6 cm 2 (P210) and 35.1 ± 3.8 cm 2 to 37.3 ± 3 cm 2 (P300) respectively. Discussion The results show that eccentric training leads to significant adaptations in muscle strength, fascicle length and ACSA. However, the preliminary results from 8 participants per group did not confirm our hypotheses of a velocity-dependent radial and longitudinal muscle adaptation. References Butterfield TA, Herzog W. OP-PM08 Liver & Mitochondria

EFFECT OF EXERCISE AND NUTRITION INTERVENTIONS ON LIVER FAT IN OBESE CHILDREN WITH NON-ALCOHOLIC FATTY LIVER DISEASE

DIAS, K.A.1, ATCHESON, N.2, COWIN, G.J.2, KEATING, S.E.1, DAVIES, P.S.W.3,4, LEONG, G.M.5,6, CAIN, P.A.7, INGUL, C.B.8, COOMBES, J.S.1

Introduction Non-alcoholic fatty liver disease (NAFLD) is the leading cause of paediatric chronic liver disease. Multi-disciplined lifestyle interventions are the cornerstone of therapy for the management of NAFLD in children, however there is minimal evidence evaluating the efficacy of these approaches individually or in combination. We therefore aimed to compare the effect of an exercise and nutrition program versus nutrition advice only on liver fat in obese children. Methods Intrahepatic lipid (IHL) was assessed in 31 obese children (BMI>95th percentile for age & sex) before and after a 12-week exercise and nutrition intervention, or a nutrition intervention alone. Exer-

cise training involved supervised aerobic exercise at 60-95% of HRpeak, for 40 min/session on 3 days per week. The nutrition component consisted of six, fortnightly dietitian consultations. IHL was measured by proton magnetic resonance spectroscopy (IHL-MRS). Ten participants (age 7.9±2.2; Tanner puberty stage 2 (2-3.25), female 30%) were identified with NAFLD (IHL>5.5%) and were included in this analysis. Cardiorespiratory fitness was assessed using a maximal treadmill test with expired gas analysis and VO₂peak was calculated. Results are presented as mean±SD or median (IQR) when appropriate. Results Participants with NAFLD had a mean baseline IHL content of 7.4% (5.8-10.4%) and VO₂peak of 30±5.4mL/kg/min. The combined intervention (n=5) resulted in significantly greater absolute reductions in IHL than the nutrition-only intervention (n=5) (-4.0±1.2% and -1.8±1.2% respectively, p=0.03), which was equivalent to a median 38% versus 7% relative reduction. This reduction was independent of improvements in VO₂peak (p=0.02). Five participants (50%) reversed NAFLD following the combined (n=4) and nutrition only (n=1) interventions. Discussion A 12-week supervised exercise program combined with nutrition advice was effective in reducing IHL in obese children. The hepatic benefits were independent of improvements in cardiorespiratory fitness. Suggested benefits of exercise on IHL include peripheral adaptations leading to lower hepatic free fatty acid uptake and enhanced skeletal muscle glucose uptake resulting in reduced substrate for lipogenesis (Johnson et al. 2012). IMPAIRED LIPID STORAGE AND MITOCHONDRIAL NETWORK ORGANIZATION IN OBESE HUMAN SKELETAL MUSCLE. IMPROVEMENTS ASSOCIATED TO GASTRIC BYPASS AND LINK TO INSULIN RESISTANCE REMISSION

MEIDLH PETERSEN, S., KRISTENSEN, M.D., MØLLER, K.E., LUND, M.T., HANSEN, M., HELGE, J.W., DELA, F., PRATS, C.

University of Copenhagen, Institute of biomedical science

Introduction: Obesity-induced insulin resistance (IR) has been proposed to be caused by lipotoxicity arising from ectopic lipid deposition and mitochondrial dysfunction in skeletal muscle. The aim of this project is to compare the amount and structural quality of lipid droplets (LDs) and mitochondrial network in morbidly obese subjects with lean sedentary controls and relate these features to improvements in insulin sensitivity (IS) during Roux-en-Y gastric bypass (RYGB)-induced weight loss. Methods: 10 obese subjects undergoing RYGB surgery were divided into normoglycemic (NGT, n=5, BMI=42.1, SEM=1.1) and type 2 diabetic patients (n=5, BMI=43.4, SEM=2.9). The subjects were tested four times, A) at inclusion, B) after an 8-10% weight loss, C) 4 months after RYGB, and D) 18 months after RYGB, where measurements were made and muscle biopsies obtained. LDs, PLIN2 and mitochondria in single muscle fibers were stained immunohistochemically using Bodipy, anti-PLIN2 and anti-COXIV, visualized with confocal microscopy and analyzed with Fiji software. LD fractional area (fa), LD density (LDd), PLIN2 fa and mitochondrial fa as well as the ratios between them were compared with lean NGT (n=5, BMI=22.0, SEM=0.7) and correlated to IS estimated by the Matsuda index. Results: Morphologically, we found that LDs became markedly smaller and more evenly distributed throughout the fibers and that the mitochondrial network became more organized from A to D in both obese groups. In the lean controls we observed disruption and disorganization of the mitochondrial network but no obvious impairments in the lipid storage. Our results show a statistically significant difference between the obese and the lean subjects at time point A when looking at LD fa (P=0.03), LDd (P=0.02), LDd/Mitochondrial fa (P=0.02) and LD fa/Mitochondrial fa (P=0.03), and that the obese significantly improve towards time point D with regards to LDd (P<0.001), LD fa (P=0.02), PLIN2 fa (P<0.001), LDd/Mitochondrial fa (P<0.001), LD fa/Mitochondrial fa (P=0.02), PLIN2 fa/LDd (P<0.001), and PLIN2 fa/LD fa (P=0.04). Analyses also show that IS correlates negatively with LDd/Mitochondrial fa (R=-0.4, P=0.008), LD fa/Mitochondrial fa (R=-0.4, P=0.006), and positively with PLIN2 fa/LDd (R=0.3, P=0.03) and PLIN2 fa/LD fa (R=0.5, P=0.001). Discussion and conclusion: Our results indicate that physical inactivity lead to impaired mitochondrial dynamics, which combined with obesity leads to impaired LD storage which coincide with reduced skeletal muscle insulin sensitivity. THE ACUTE COLD-INDUCED INCREASE IN PGC-1A IS MEDIATED SYSTEMICALLY THROUGH INCREASED β-ADRENERGIC STIMULATION.

ALLAN, R., SHARPLES, A.P., CLOSE, G., DRUST, B., SHEPHERD, S., FRASER, W., MAWHINNEY, C., HAMMOND, K., MORTON, J.P., GREGSON, W.

Liverpool John Moores University

INTRODUCTION Post-exercise cold water immersion (CWI) increases the PGC-1a mRNA response to exercise (Ihsan et al. 2014). The molecular mechanisms mediating this response are yet to be fully elucidated but may involve upregulation of the local signalling kinases AMPK and p38 MAPK (Ihsan et al. 2015) and/or increased systemic β-adrenergic stimulation (Puigserver et al. 1998; Ihsan et al. 2014). Using a single leg immersion protocol our aim therefore was to examine whether the cold-induced post exercise increase in skeletal muscle PGC-1a mRNA is locally and/or systematically mediated. METHODS In a repeated measures cross-over design 10 active subjects completed high-intensity intermittent cycling (8 x 5 minute bouts separated by 60 sec rest, ~80% peak power output) followed by seated rest (CON) or single-leg cold water immersion (CWI; 10 min, 8°C). Muscle biopsies of the immersed (CWI) and CON legs were taken pre-, post- and 3h post-exercise. In the non-immersed leg (NOT) biopsies were taken post- and 3h post-exercise. qRT-PCR and Western Blots were performed to assess gene expression (mRNA) and signalling kinase activity respectively. Plasma normetanephrine concentration was used as a measure of the systemic β-adrenergic response. Two factor (condition × time) within-subjects GLM with repeated measures determined treatment differences. LSD pairwise comparisons was used to locate the difference. RESULTS Exercise per se induced increases in PGC-1a mRNA 3h post-exercise (~5-fold; P < 0.001). These changes were further elevated following CWI (~9-fold; P < 0.001) and were similar in both CWI and NOT (~12-fold; P < 0.05). Plasma normetanephrine concentration was higher in CWI vs. CON (P = 0.034) (860 vs. 665 pmol/L post-immersion). DISCUSSION We report for the first time that local cooling of the immersed limb evokes transcriptional control of PGC1-a in the non-immersed limb. This suggests that increased systemic β-adrenergic stimulation, and not the effects of localised cooling on skeletal muscle signalling kinases, mediates the post-exercise increases the PGC-1a mRNA. Results from the present study have important implications for research designs which adopt contralateral non-immersed limbs as a control condition, whilst presenting new directions for mechanistic research into cold-induced PGC-1a responses. SKELETAL MUSCLE MITOCHONDRIAL QUALITY CONTROL AND MITOPHAGY IN OBESE AND ENDURANCE TRAINED MEN

JOANISSE, D.R.1, HUTH, C.1, CHEN, C.C.W.2, HOOD, D.A.2

1: U. Laval (Québec, Canada), 2: MHRC, York U (Toronto, Canada)

Introduction Mitochondrial content is determined by coordinated biogenesis and degradation processes. An increase in mitochondrial volume occurs from organelle biogenesis and fusion to the existing reticulum. Decreased volume occurs with the removal of dysfunctional portions of the reticulum through fission. Mitophagy, a selective form of autophagy targeting mitochondria with a depolarized membrane potential, works in conjunction with fission to degrade portions of the reticulum that cannot be repaired. In obesity and diabetes, conditions associated with reduced muscle mitochondria content, the state of fusion and fission and the role of mitophagy remain unclear. The aim of this study was to compare the levels of a number of fusion, fission, and mitophagy-related proteins in muscle from men varying for fitness, obesity and insulin sensitivity. Methods Vastus lateralis m. biopsies were obtained from 42 men aged 34-53 yrs in 4 groups: non-obese sedentary (S: BMI<25kg/m²), sedentary obese (OB: BMI>30kg/m²), sedentary glucose intolerant obese (OBI), and endurance-trained non-obese (ET). An OGTT was used to assess glucose tolerance, a euglycemic-hyperinsulinemic clamp to measure insulin sensitivity (M/I), and a cycle ergometer incremental test to exhaustion to assess VO_{2max}. Protein levels were assessed by Western blotting, and enzyme activities measured spectrophotometrically. Results ET had VO_{2max} values ~80% greater than the OB and OBI, S only slightly more fit than the obese. ET had the greatest insulin sensitivity (M/I, ~50% greater than obesel). Muscle cytochrome-c oxidase (COX) and citrate synthase (CS) activities were respectively ~73% and ~94% greater in the ET. An ~50% higher level of the fusion protein Opa1 was observed in the ET, the lowest levels in the obese groups. No differences were seen for the fission proteins Fis1 and Drp1. OBI muscle also had ~50% less of the anti-mitophagy PARDL and ~100% more of the pro-mitophagy Parkin. OPA1 levels correlated negatively with obesity (r range ~-0.32 to -0.34), and positively with VO_{2max} (r=0.36) and COX (r=0.36). Similarly, PARDL levels correlated negatively with obesity (r range ~-0.39 to -0.46), and positively with VO_{2max} (r=0.52) and mitochondrial enzymes (CS, COX, r range 0.53 to 0.59). In contrast, Parkin levels did not correlate with obesity or fitness, but were negatively associated with mitochondrial activities (CS, HADH, r range -0.31 to -0.43). Discussion Decreased muscle mitochondrial content in obesity with or without impaired glucose tolerance appears to result from decreased fusion and increased mitophagy. Endurance training could increase mitochondrial content in these subjects through its specific effects reversing these processes. Contact Denis.joanisse@kin.ulaval.ca

OP-PM47 Physiological Response to HIT

HIGH-INTENSITY EXERCISE TRAINING ABROGATES AGE DIFFERENCES IN SPOMATOTROPIC HORMONE CONCENTRATIONS

SELLAMI, M., BEN ABDERRAHMEN, A., HAYES, L.D., KEBSI, W., ZOUHAL, H.

Rennes 2 University

Aim: The aim of this investigation was to compare systemic concentrations of growth hormone (GH), Insulin-like growth factor 1 (IGF-1), and Insulin-like growth factor-binding protein (IGFBP-3) in response to a combined sprint and strength training program in young and middle-aged men. **Methods:** Thirty-eight healthy, moderately trained men participated in this study. Young and middle-aged men were randomly assigned into two experimental conditions (training or control). A young training group (21.4±1.2yrs, YT, n=10), a young control group (21.3±1.3yrs, YC, n=9), a middle-aged training group (40.4±2.1 yrs, MAT, n=10) and a middle-aged control group (40.3±1.7 yrs, MAC, n=9) were assessed before (P1), and after (P2) a high-intensity sprint and strength training program (HISST) for 13 weeks (4 times/week). At P1 and P2, maximal oxygen uptake (VO_{2max}) and maximal anaerobic power was assessed using the Wingate Anaerobic Test (WAnT). Blood samples were collected at rest, after warm-up (50% VO_{2max}), immediately post-, and 10 min post-WAnT. **Results:** Resting serum GH, IGF-1, and IGFBP-3 increased significantly ($p<0.05$) after HISST in MAT. This increase approached values to those of YT after HISST. In response to warm-up and the WAnT, GH and IGF-1 levels increased significantly ($p<0.05$) in YT and MAT after HISST. VO_{2max} and maximal anaerobic power increased ($p<0.05$) after HISST in both YT and MAT compared to YC and MAC. **Conclusion:** These data suggest combined sprint and strength training improves muscle power, VO_{2max}, and increases activity of the GH/IGF-1 axis. Moreover, GH/IGF-1 axis sensitivity to a WAnT in middle-aged men was additionally increased. However, the causal of these hormonal adaptations remains to be clarified.

HIGH INTENSITY INTERVAL TRAINING IMPROVES GLUCOSE METABOLISM IN DIABETIC MICE DESPITE THE ABSENCE OF MITOCHONDRIAL ADAPTATIONS

CHAVANELLE, V., BOISSEAU, N., MAILLARD, F., COMBARET, L., DARDEVET, D., MONTAURIER, C., DENIS, P., METZ, L., PELTIER, S., SIRVENT, P.

AME2P - EA 3533

Introduction Type 2 diabetes (T2D) is a long term metabolic disorder characterized by high blood glucose level, insulin resistance, and relative lack of insulin. Recent studies have proved in patients with T2D the positive effects of High Intensity Interval Training (HIIT) programs on hyperglycemia and muscle mitochondrial capacity (Little et al., 2011). The aim of this work was to compare the effects of HIIT with a traditional Moderate Intensity Continuous Training (MICT) on glucose metabolism and mitochondrial function in diabetic mice. **Methods** 30 db/db mice aged 6 weeks were subdivided into MICT group, HIIT group, or control group (CON). Animals in the training groups ran on a treadmill 5 days/week during 10 weeks. In vivo starch and insulin tolerance tests were performed at the end of the protocol along with 24h respiratory measurements realized in metabolic chambers. In vitro measurements included high resolution respirometry, assessment of mitochondrial density markers (Citrate synthase and β-Hydroxyacyl-CoA activities and oxidative phosphorylation complexes protein content) and insulin signaling by enzymatic assays and western blot in muscle and liver. **Results** HIIT lowered fasting glycemia (~40%) and % HbA1c (~20%), and improved response to starch and insulin tolerance tests compared to CON group. No changes were noted in MICT group regarding the glucose homeostasis. 24h respiratory exchange ratio was increased in HIIT (+6%) and

MICT group (+4%) after the training program but without any changes in 24h total energy expenditure. Assessment of muscle and liver mitochondrial density markers and ex vivo gastrocnemius mitochondrial respiration showed no differences between the three groups. Western blot analysis revealed a significant 2-fold increase of muscle Glut4 content only in HIIT group. Similarly, only HIIT increased liver Foxo1 phosphorylation ratio and decreased JNK phosphorylation ratio. Discussion This study showed that HIIT may improve glucose metabolism more efficiently than traditional MICT in diabetic mice by mechanisms independent of mitochondrial adaptations, as already reported in the literature (Li et al. 2011). This effect could be partly explained by an increased muscle GLUT4 content, and a decreased activity of JNK/FoxO1 pathway in the liver, both involved in the pathophysiology of insulin resistance (Cheng & White, 2011). LOW-VOLUME HIGH-INTENSITY INTERVAL EXERCISE IMPROVES GLYCAEMIC CONTROL SIMILARLY TO CONTINUOUS MODERATE-INTENSITY EXERCISE DESPITE INCREASED POSTPRANDIAL OXIDATIVE STRESS.

PARKER, L., SHAW, C., BANTING, L., HILL, K., MCAINCH, A., LEVINGER, I., STEPTO, N.

Victoria University

Background: Meal consumption increases circulating blood glucose and oxidative stress which, if in excess, can lead to chronic disease. Acute exercise can reduce postprandial oxidative stress (PPOS) and glycaemia and improve metabolic health, however the effects of exercise intensity are unclear. We investigated the effects of low-volume high-intensity interval exercise (LV-HIIE) and continuous moderate-intensity exercise (CMIE) on PPPOS and glycaemic control in overweight and inactive adults. **Methods:** Twenty-seven adults were randomised into LV-HIIE (9 females, 5 males; age: 30±1 years; BMI: 29±1 kg/m²; M±SEM) or CMIE (8 females, 5 males; age: 30±2.0; BMI: 30±2.0) groups. Participants consumed a standard breakfast (cereal and milk) on a non-exercise day and an exercise day. On the non-exercise day, participants rested in the laboratory. On the exercise-day, participants performed a single session of LV-HIIE (8x1 min cycling bouts @ 100% Wmax, 1 min recovery periods) or CMIE (38±1 mins of continuous cycling @ 50% Wmax) 1 hr after consuming breakfast. Plasma oxidative stress (TBARS and hydrogen peroxide; H₂O₂) and antioxidant activity (catalase and superoxide dismutase; SOD) were measured at baseline, 1hr postprandial (pre-exercise) and 3 hrs postprandial (1.5 hrs post-exercise). A continuous glucose monitor (CGM) was used to measure 24 hr glycaemic control over the rest and exercise day. **Results:** On the non-exercise day, plasma oxidative stress and antioxidant activity were increased 1 hr (H₂O₂: 23%; TBARS: 35%; catalase: 41%; SOD: 15%) and 3 hrs postprandial (H₂O₂: 22%; TBARS: 20%; catalase: 26%; SOD: 16%); and increased 1 hr post-prandial (prior to exercise) on the exercise day (H₂O₂: 40%; TBARS: 29%; catalase: 50%; SOD: 21%). CMIE performed 1 hr after breakfast attenuated the 3 hr PPPOS response (H₂O₂: -14%; TBARS: -23%; SOD: -12%), whereas this response was exacerbated with LV-HIIE (H₂O₂: 27%; TBARS: 25%; catalase: 25%). Compared to the non-exercise day, both LV-HIIE and CMIE similarly decreased CGM 24 hr average glucose levels (-6% and -4%), area under the curve (-6% and -4%), peak glucose concentrations (-9% and -12%) and the 2 hr postprandial glucose response to dinner (-11% and -8%). **Conclusion:** In contrast to CMIE, LV-HIIE performed 1 hr after breakfast did not attenuate PPPOS. Despite this, LV-HIIE provided similar benefits in glycaemic control over a 24 hr period, and consisted of 30% less total work and a substantially lower time requirement. LV-HIIE may therefore be a convenient exercise model for improving glycaemic control in overweight and inactive populations.

HOW INTERVAL TRAINING AND PROBIOTIC SUPPLEMENTATION AFFECTS THE COGNITIVE FUNCTION IN A TRANSGENIC MICE MODEL OF ALZHEIMER'S DISEASE?

ABRAHAM, D., FELSZEGHY, K., CSERVENAK, M., DOBOLYI, A., FEHER, J., RADAK, ZS.

University of Physical Education

Over 46 million people live with dementia worldwide, Alzheimer's disease (AD) contributes to 60-70% of cases. The illness is associated with the loss of acquired knowledge and the ability to learn. Inflammation and neuron loss indicated by amyloid-beta peptide accumulation underlies this disease. So far there is no effective treatment, but it is proven that physical exercise protects against neurodegenerative diseases, while numerous studies support the positive effects of healthy gut flora on these processes. **Experimental design:** A total of 32 APP/PS1 transgenic male mice were in the experiment. 8-8 animals in control, exercise, probiotic supplementation (Framelim) and combined treatment groups, respectively. 20 weeks of interval treadmill running and/or probiotic supplementation were used. **Aims:** We suggest that the use of interval treadmill running and the probiotic supplementation attenuates the ongoing loss of cognitive function, delays the AD progress and reduces the cerebral inflammation caused by the illness. **Results:** Cognitive test revealed the continuous development in the performance of the animals on combined treatment. During Morris Water Maze test, on the second day the animals showed significantly better performance, the 3rd and 4th day revealed a tendency for improved learning skills compared to the control group. Also in the spontaneous alternation test, a remarkable increase in performance was observed, demonstrating better exploratory activity, and better preservation of cognitive function. 6E10 immunohistochemistry against beta-amyloid plaques revealed, that the number of plaques in hippocampus in the exercise group were significantly lower than in the control and combined group. The plaque area in the hippocampus was significantly lower in all treated groups when it compared to the control group. This suggests an absence of direct link between cognitive function and the number of plaques. Astrocytes were stained with anti-S 100 antibody. We observed an increased number of astrocytes around the plaques, however significant differences in the density of astrocytes in different groups were not found. This phenomenon presumes an increased astrogliosis due to neuron damage in the plaque area. Our results confirm that physical exercise and the use of probiotics can ameliorate cognitive function in AD, however further investigation is needed to prove its effects on cerebral inflammation and neuronal loss.

OP-PM55 Low Back Pain

OBJECTIVELY MEASURED MODERATE TO VIGOROUS PHYSICAL ACTIVITY BUT NOT SEDENTARY BEHAVIOUR IS ASSOCIATED WITH LOW BACK PAIN

SUNI, J.H.1, TOKOLA, K.1, VÄHÄ-YPYÄ, H.1, HUSU, P.1, KOSKINEN, S.2, SIEVÄNEN, H.1, VASANKARI, T.1

UKK Institute (Tampere, Finland), 2: THL (Helsinki, Finland)

Introduction Low back pain (LBP) is a common and costly condition with high absence from work. Insufficient physical activity (PA), excess SB and poor physical fitness are potential risk factors for LBP. Former research on PA and SB relies on questionnaire data with known biases. The purpose of this study was to investigate the independent associations of actual PA, SB and fitness on self-reported (1) occurrence of LBP (yes/no) and (2) LBP with at least one visit to physician during the past 12 months. **Methods** Participants (n=1156) were men and women aged 30 to 69 from PA and fitness sub-sample of the national Health 2011 Survey who had sufficient (min 4days with at least 10h/day) accelerometer data (Hooke AM20, Traxmeet Ltd, Espoo, Finland), performed the six minute walk test (6MWT) and answered questions on LBP. PA parameters were based on the mean amplitude deviation (MAD), derived from raw data with validated cut-points. Epoch length was 6 seconds, a single MAD value the 1min exponential moving average. The accelerometer position on the waist (i.e. the angle of postural estimation, APE) was determined by the direction of Earth's gravity vector and upright walking posture. PA/SB parameters, calculated as the mean of daily values were (a) highest metabolic equivalent (MET) level of specific bout durations (1, 5, 10, 15, and 30min), (b) accumulated time of specific bouts of MVPA/light PA/ standing/sitting/lying,(c) number of >30min bouts of standing/sitting/lying and (d) number of standing ups. Multivariable logistic regression analysis were conducted between LBP and PA, SB and fitness, adjusting for age, sex, civil status, education, smoking and body mass index. **Results** The highest MET levels of all bout durations except 1min, and accumulated daily time of MVPA bouts of at least 5 and 10min had strong associations ($p \leq 0.001$) with occurrence of LBP. The highest daily MET 15min had odds ratio (OR) of 0.80 (95% confidence interval (CI) from 0.71 to 0.91), the MET level being 4.1 for those without LBP (n=869) and 3.7 for those with LBP (n=287). Fitness, light PA and SB were not associated with occurrence of LBP. Accumulated daily time of MVPA bouts at least 5 and 10min and number of 10 min bouts showed strongest associations ($p=0.002$) with visits to physicians due to LBP (n=76), the latter having OR of 0.46 (95% CI from 0.29 to 0.75). **Discussion** Higher amount of MVPA was associated with lower occurrence of LBP and less visits to physician in Finnish adults even after further adjusting for SB and fitness. Prospective studies are needed to assess causality. Contact [jaana.h.suni@uta.fi]

MULTISENSORY TRAINING RELATED LOW BACK PAIN

SHALAJ, I., CAKA, A.I., GASHI, F.1

University of Pristina

Introduction If asymmetric forces act on the body for long time and muscles cannot balance these forces maladaptation will occur, which might result in chronic musculoskeletal problems like spine deformities later on (Steinhaug, 2005). All of the forces that maintain the normal posture must be in balance (Jovovoč, V., 2008). **Purpose** The aim of this study was to investigate the relationship between the quality of body posture (based on static and dynamic balance) and back pain syndromes and to study the effectiveness of a multisensory therapeutic exercise intervention on pain and postural control markers, respectively. **Methods** 53 patients (30 male and 23 female, respectively), age: 35.2 ± 4.1 yrs.; body mass 74.2 ± 6.7 kg; height 180.0 ± 5 cm) were tracked, suffering from back pain. Baseline assessment was performed before starting the exercise program and included ODI questionnaire and balance assessment. Body-stability and functional movement symmetry assessment was performed using MFT-S3-Check device TST GmbH, Austria. Re-evaluation was performed immediately following the 3 months of exercise intervention. Multisensory intervention training program was applied (12 weeks; 3 times per week; 40 min per session), in a way that all different analyzers included in sensorimotor tasks. Descriptive and analytical procedures were performed using SPSS. Results Oswestry Disability Index (ODI) significantly ($p < 0.000$) decreased following 12 week of therapeutic exercise intervention, demonstrating that severity of pain and disability was significantly lower following exercise treatment. Initially 40 clients were enrolled into ODI stage 2 (79.8%) and 13 into ODI stage 3 (20.2%), respectively. Following the exercise intervention 41 patients (82.1%) improved to stage 1 according to ODI, 9 (10.9%) improved to ODI stage 2, and only 3 patients (7%) did not improve and remained in stage 3 according to ODI. . Body-stability and functional movement symmetry characteristics both improved significantly ($p < 0.01$) following 12 weeks of exercise treatment. **Conclusion** Exercises treatment may be helpful for patients with chronic low back pain to increase return to normal daily activities and work. THE INTERVERTEBRAL DISC POSITIVELY ADAPTS TO RUNNING EXERCISE

BELAVY, D.L.1, QUITTNER, M.1, RIDGERS, N.1, CONNELL, D.2, RANTALAINEN, T.1

1: Deakin University (Melbourne, Australia), 2: Imaging at Olympic Park (Melbourne, Australia)

Introduction Muscle, bone and tendon tissues are known to respond positively to specific exercise types. Yet for the intervertebral disc (IVD), this is not clear. Certain sport types such as swimming, gymnastics, volleyball, rowing, baseball, are known to have negative effects on the IVD, resulting in more IVD degeneration (reviewed in Belavy et al, 2016). But it is not known what exercise in humans can impact positively on the IVD, if any. A healthy IVD is evinced by a well-hydrated nucleus pulposus (i.e. high T2-relaxation time on magnetic resonance imaging) with clear distinction between the nucleus and annulus. We hypothesized that IVDs in people who performed regular jogging and running would have higher T2-relaxation time than individuals who performed no sport. **Methods** 25 long-distance runners (>50km per week, minimum of 5 years, no other sports), 30 joggers (20-35km per week, minimum of 5 years, no other sports), and 24 sedentary referents who performed no exercise in the last 5 years were included. All subjects were aged between 25 and 35yrs. Age, height and proportion of females to males were similar across groups. All scanning was done after midday and a minimum of 20 minutes sitting prior to scanning was strictly enforced. T2-relaxation time was quantified in the lumbar IVDs (for the entire IVD, annulus subregion and nucleus subregion), via magnetic resonance imaging. **Results** Long distance runners showed the highest lumbar IVD T2-

time values (mean[SD]: 115[15]ms) being 11% higher than sedentary referents ($p=0.0009$). Joggers had an IVD T2-time of 113[13]ms which was 9% higher than the referent group ($p=0.0014$). This effect was strongest in the hydrated, nuclear, region of the disc. The T2-time in the nucleus pulposus of long-distance runners was 15% ($p=0.0011$), and joggers 11% ($p=0.003$), higher than the referent group. In the annular region the difference was +7% ($p=0.005$) and +5% ($p=0.025$) respectively. The positive impact of long-distance running was also significant at the L3/4, L4/5 and L5/S1 vertebral levels. Discussion This is the first study to show that certain exercise types can have a positive effect on the IVD. Specifically, running sports were associated with better IVD hydration (higher T2-time) with this effect being strongest in the IVD nucleus pulposus. Importantly, the effect was present at the lower lumbar IVDs which are those most commonly affected by disc degeneration in the community. This contradicts the wide-spread assumption (Adams & Roughley, 2005) that repetitive loading is necessarily negative for the IVD. References Adams MA & Roughley PJ. (2005). Spine 31: 2151-2161. INCIDENCE OF BACK INJURIES IN YOUTH FLOORBALL AND BASKETBALL: A PROSPECTIVE THREE-YEAR FOLLOW-UP STUDY

ROSSI, M.1, PASANEN, K.1, HEINONEN, A.2, KANNUS, P.3, PARKKARI, J.1

Tampere Research Center of Sports Medicine

1 Tampere Research Center of Sports Medicine, UKK Institute for Health Promotion Research, Tampere, Finland 2 Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland 3 Injury and Osteoporosis Research Center, UKK Institute, Tampere, Finland INTRODUCTION In Finland, nearly half of adolescents aged 10–16 years take part in organized sports club activities, floorball and basketball being among the 10 most popular sports. Sports is one of the leading causes for injuries and various musculoskeletal disorders in adolescents. Team sports and sports comprising pivoting movements possess increased risk of injury. The aim of this prospective study was to investigate the incidence and nature of back injuries among young floorball and basketball players in Finland. METHODS Four-hundred- and-twenty-nine adolescent basketball ($n=109$ female and $n=102$ male) and floorball ($n=106$ female and $n=112$ male) players entered the study (mean age 16.4), of whom 266 were observed prospectively for one, 87 for two and 76 for three study years. Total of 642 athlete-years were collected (2011 to 2014). During the follow-up, all time-loss back injuries were registered weekly and verified by a study physician. RESULTS Altogether 72 back injuries were reported by the players ($n=422$). Two thirds were overuse injuries ($n=46$, 63.0%) and most of them were at the lower back ($n=42$, 89%). Total of 36 low back and pelvis injuries occurred in floorball players and 32 in basketball players. The overall incidence of low back injuries was 91.9/1000 athlete-years. Respectively, the incidence of upper back injuries was 9.4 and that of pelvic injuries 15.6. 42.6% ($n=20$) of the overuse injuries and 15.0% ($n=6$) of the acute injuries were classified as severe (over 29 days time-loss from sports). DISCUSSION The overall unadjusted incidence of back injuries is high in adolescent floorball and basketball players. Our results showed that overuse injuries were more common than acute traumatic injuries. In the future plausible predisposing factors should be investigated to prevent back problems among adolescent floorball and basketball players. CONTACT marleena.rossi@gmail.com

PREVENTIVE PROFILING – A SYSTEMATIC APPROACH TO PREDICT THE ONSET OF LOW BACK PAIN

ERHARDT, R.1, KREUZPOINTNER, F.1, MÜHLHAUS, T.1, EIBL, F.2, SCHWIRTZ, A.1

1: Technical University Munich (Munich, Germany); 2: egym GmbH (Munich, Germany)

INTRODUCTION Costs for the treatment and rehabilitation of chronic low back pain (LBP) represent a great part of the yearly expenses in the healthcare system [1]. Research activities in this area increased in the past years, but the synergy of factors leading to LBP can not be fully explained. It is a complex construct: Single trials with a necessarily high number of subjects can only investigate some selected parameters. The inhomogeneity in the study designs leads to a limited validity of systematic reviews and meta analysis trying to combine the results of those single trials. METHODS As a first step a systematic literature review is in process, which investigates the synergy of physical parameters indicating LBP. Focusing on an available dataset, this literature search will obtain information about norm values and the influence of the following selected parameters on the development of LBP: muscle strength, flexibility, physical capacity, body weight, body composition (e.g. BMI), blood pressure, coordination, somatotype, body height, gender and age. In the second step a Mega Trail will examine a consistently growing dataset with more than 500.000 subjects to proof, if the literature based assumptions can be verified and quantified. PRELIMINARY RESULTS The systematic literature search for LBP in the databases pubmed, SportDiscus, Web of Science and Cochrane Library resulted in 8228 articles. The dataset contains currently 559.905 subjects, 280.058 women and 279.847 men. The average age of the female subjects is 39.0 ± 11.7 yrs, the male subjects are 45.5 ± 13.0 yrs. Within the sample, 10.827 subjects state the presence of LBP. First results support the literature, that women are more likely to develop LBP [3]. 62% of the subjects suffering from LPB are female. Another risk factor is age and BMI. The main risk group of LBP is 40–59 yrs old and has a normal BMI [3]. The female subjects in our dataset with LBP are 39.5 ± 12.6 yrs with a BMI of 25.8 ± 5.2 and the male subject are 44.7 ± 13.2 yrs with a BMI of 27.1 ± 4.2 . This indicates a very good dataset for studying the dependency on risk factors for LBP. OUTLOOK Based on the given parameters and the perceptions of the literature review the structure of a multidimensional radar chart will be created. The analysis of the influences of each single parameter and the interaction between the dependent variables will be quantified by the Mega Trail and are still ongoing. The resulting preventive profile might be used as early-warning system to identify the risk for LBP.

MUSCLE STRENGTH AND NEUROMUSCULAR CONTROL OF SPINE STABILITY IN LOW BACK PAIN: ELITE ATHLETES VERSUS GENERAL POPULATION

MORENO CATALÁ, M., SCHROLL, A., LAUBE, G., ARAMPATZIS, A.

Humboldt-Universität zu Berlin

Introduction Chronic low back pain (LBP) is a worldwide-recognized problem with dramatic consequences for the quality of life of the affected patients. There is evidence that LBP patients show deficits in the neuromuscular control of the spine stability compared to healthy controls (Graham, 2014; Hodges, 2009). However, there is a lack of studies taking into account the specificity of LBP in competitive sports. Our purpose was to investigate the athletic-based specificity of neuromuscular differences between healthy and LBP individuals and to identify appropriate markers for the characterization and evaluation of LBP. Method Two groups of athletes with ($n=15$) and without LBP ($n=15$) and two groups of non-athletes with ($n=15$) and without LBP ($n=14$) participated in the study. Muscle strength of the trunk was assessed during maximal isometric and isokinetic contractions using dynamometry. To quantify the neuromuscular control of trunk stability we examined trunk stiffness and damping as well as muscle response patterns using Quick Release experiments. Furthermore,

we investigated the local dynamic stability of the spine using the maximum finite-time Lyapunov exponent (λ_{\max}) under static and dynamic conditions. For the statistical analysis a two-way ANOVA was performed. Results The maximum isometric trunk extension moments were significantly lower in the LBP participants compared to healthy controls in both athletes and non-athletes. The analysis of interaction between condition (LBP) and groups showed that trunk stiffness was lower only in the non-athlete LBP participants. Trunk damping was significantly higher for the LBP participants in both groups. No significant differences were found in the muscle reaction times and in λ_{\max} between groups and conditions. Discussion Isometric muscle strength decrease of the trunk extensors is a LBP specific characteristic in athletes as well as in non-athletes. This provides evidence that this parameter is a suitable marker for the evaluation of LBP. Trunk stiffness is not sensitive enough to distinguish LBP participants from healthy controls in elite athletes, indicating an athletic-based specificity in the neuromuscular control of spine stability. OP-PM36 Handball Performance

TEAM HANDBALL MATCH ANALYSIS BY COMPUTER TRACKING FROM THE MEN'S EUROPEAN CHAMPIONSHIPS 2016

MICHALSIK, L.B.1, SØNDERGAARD, H.2, FLYNN, M.3

1Department of Sport Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark, 2YouShape, Copenhagen, Denmark, 3Performance. Lab, Prozone Sports Ltd, Leeds, United Kingdom

Introduction Using time-motion analysis in team handball (TH) has some limitations, since this analysing method is influenced by subjective assessments and does not actually measure the precise locomotion speed. Now a new analysing system has been developed by Prozone Sports, which measures the actual locomotion speed of the players, and in addition can account for all changing actions, i.e. accelerations and decelerations, that occur during match-play even when the speed is low. Methods The activity pattern of top international male elite TH players were evaluated by computer tracking at the men's European Championships 2016 in Poland during matches in the main round. The matches were recorded using a three camera setup (Baumer TXG13c) in order to gain full coverage of the TH court. The three videos were independently tracked to produce trajectories and events for each individual player based on the video images. As a result the players are not required to wear a device, and the system is able to capture both playing teams. The player's on-court coordinates are then analysed by quality control operators to verify the player trajectories and events. Finally, software quantifies the locomotion and technical variables for each player and team. Results The mean total playing time (TPT) per match for all players (n=136) including all stoppages, but excluding the half-time break, was 77.12 ± 3.11 min (group means \pm SD), corresponding to 28.5 % extension compared to the normal effective match time of 60 min. In average, wing players (WP) played longer (50.46 ± 23.39 min~65.4% of TPT, $p<0.05$) than goalkeepers (G: 42.60 ± 28.55 min~55.2%), pivots (PV: 35.11 ± 20.65 min~45.5%) and backcourt players (BP: 34.27 ± 20.25 min~44.4%), respectively. The mean total distance covered (TDC) for field players (FP, n=118) was 2915 ± 1662 m with a mean playing time of 38.40 ± 22.23 min (~49.8% of TPT, range: 0.9–80.4 min). WP covered a longer mean total distance (3987 ± 1778 m, $p<0.05$) than the other playing positions (BP: 2574 ± 1491 m; PV: 2562 ± 1363 m, G: 1550 ± 1077 m). For FP with long on-court playing time (61.80 ± 10.52 min~80.1% of TPT), TDC per match was 4625 ± 863 m. High-intensity running (HIR) constituted only 1.8 ± 1.0 % of TPT corresponding to 8.8 \pm 4.6 % of TDC. However, in relation to the total effective playing time of 60 min, HIR constituted for FP 2.5 \pm 1.3% and was higher for WP (4.2 \pm 2.8 %, $p<0.05$) compared to the other playing positions (PV: 2.1 \pm 3.8 %; BP: 1.6 \pm 2.9 %, G: 0.02 \pm 0.2 %). Furthermore, FP performed a mean of 76 ± 124 accelerations and 66 ± 105 decelerations when the speed was low, where WP performed the highest number compared to all other playing positions (102 ± 117 , 86 ± 112 , $p<0.05$). Conclusions Match analysis by computer tracking showed that male top international elite TH imposes moderate-to-high demands on the aerobic energy system and very high demands on the anaerobic energy systems during certain periods of the match. The activity pattern differed markedly between playing positions, with WP showing a more intense locomotion activity profile than BP, PV and G.

SCIENCE BASED TRAINING IN ELITE MALE TEAM HANDBALL

WAGNER, H., AJAYI, S., VON DUVILLARD, S.P.

University of Salzburg

Introduction Team handball is an Olympic sport game that is very popular in Europe. In most of these countries, the leading teams are managed very professionally. However, professional training in elite team handball is mostly based on practical experience because science based knowledge is lacking. Consequently, the aim of this study was to generate and perform professional training based on scientific tests in an elite male handball team. Methods 16 (2 goal keepers and 14 field players) elite male team handball players performed a game based performance test (Wagner et al., 2014) consisting of an incremental treadmill-running test, a 30m sprinting test, lower and upper body strength test, and a counter movement jump (CMJ) test at the beginning and at the end of the first (general), at the end of the second (specific) preparation phase as well as at the end of the primary round in the Handball League Austria (HLA). We measured peak oxygen uptake (VO_{2peak}), utilizing portable metabolic system (Cosmed K4B2), peak blood lactate concentration (BLCpeak) (EKF, Biosen C), heart rate (Polar, Kempele, Finland), sprinting time, offensive and defensive time actions (Inmotion LPM-system, Abotec, Austral), ball velocity and jump height during a jump throw (PeakMotus, Vicon Peak, UK), isometric leg force and shoulder and trunk rotation torque (ISOMED, D&R Ferstl, Germany) and jump height in the CMJ (AMTI, Watertown, USA). Based on results of the performance tests, the focus in training, adjacent to the normal team handball training, was the polarized endurance (threshold and high-intensity interval) training (Stöggli et al., 2014) in the first and team handball specific coordination and endurance training in the second preparation phase and strength training during the primary round in the HLA. One-way analysis with repeated measures was used to determine the increase in performance. Results We found a significant increase in VO_{2peak} ($P<.01$) in the first and second preparation phase, in sprinting time ($P<.001$), offensive time ($P<.001$), defensive time ($P<.001$) and jump height in the jump throw ($P<.001$) in the second preparation phase as well as in the isometric leg force ($P<.01$) during the primary round in the HLA. It was remarkable that the increase in VO_{2peak} was 0.8 l/min (4.1 l/min at the beginning of the first and 4.9 l/min at the end of the second preparation phase) and a decrease in the defensive time 0.6 s (6.4 s at the beginning of the first and 5.8 s at the end of the second preparation phase). Discussion The present study revealed that the use of scientifically based training method enables a significant increase in specific endurance and agility in elite

team handball players within the preparation phase of a regular season. We propose that this combined effect of scientific tests and practical training is also appropriate to increase performance in other elite team sports. References Wagner H, et al. (2014). SEASONAL VARIATIONS OF PERFORMANCE PARAMETERS IN FEMALE ELITE HANDBALL

KOLODZIEJ, M., SCHMIDT, M., JAITNER, T.

TU Dortmund

Introduction For elite handball players, a high level of physical fitness is of particular importance not only to improve performance but also to prevent injuries. Up to now, less empirical evidence is given how physical performance changes over season (Granados et al., 2008). Furthermore, changes of injury risk parameters haven't been investigated yet. Especially for female athletes, injuries in lower extremities (e.g. ACL rupture) must be considered as a severe problem. For this reason, this study investigates changes in performance parameters and potential injury risk factors of the lower extremities of elite female handball players during the competition season. Methods 16 elite female handball players of the first national league (mean age 25.8 +/- 3.6years) were tested at the end of the preparation (T1) and the first competition period (T2). The assessment included 20m sprint test, drop jump test (DJ), landing technique test (LESS), Functional Movement Screen (FMS) as well as lactate threshold test. Sprint times at 0-5m (t5) and 0-20m (t20), velocity (v) and heart rate (hf) at 4mmol blood lactate threshold, contact time (ts) and reactive strength index (RSI) as well as LESS Score and FMS Score were determined. T-test ($p \leq 0.05$ criterion) and Cohens d were calculated. Results Sprint times for 5m (T1: 1.2 ± 0.1s; T2: 1.2 ± 0.1s) and 20m (T1: 3.4 ± 0.1s, T2: 3.4 ± 0.1s), FMS Score (T1: 17.3, T2: 17.5), hf (T1: 171, T2: 174bpm) and v (T1: 13.1m/s, T2: 13.2m/s) did not show any substantial differences for both measures. LESS Score decreased 14.5% (5.5 to 4.7) whereas RSI increased 4.8% (150 to 157). Both didn't show any statistical significance. Only ts decreased significantly ($p=0.012$; $d=0.388$) between T1 (194.4ms) and T2 (175.9ms). Discussion Changes of ts and RSI indicate an increased reactive strength of the lower extremities, whereas – in accordance to Granados et al. (2008) - sprint and endurance parameters remained stable. These findings confirm that a specific level of physical performance acquired in the preparation period can be maintained and partly improved during the first competition period in elite female handball players. In addition, the risk of being injured did not rise as potential injury risk factors decreased tendentially. For deeper insight in the development of performance parameters and injury risk factors longitudinal studies are needed that also consider how training contents and loads correspond with performance and risk of injury. References Granados, C., Izquierdo, M., Ibanez, J., Ruesta, M., & Gorostiaga, E. M. (2008). Effects of an entire season on physical fitness in elite female handball players. EFFECTS OF PRE-COMPETITIVE PREPARATION PERIOD ON THE EVOLUTION OF ISOKINETIC PROFILE IN INTERNATIONAL PROFESSIONAL HANDBALL PLAYERS

MAURELLI, O.

Université d'Amiens

Introduction Handball is a team sport played between two teams of seven players on an area of 40 m long and 20 m wide, for 2 periods of 30 min. In team sports, such as handball, in order to prepare for the very long period of competition, the pre-competitive preparation period (Pc2P) usually involves the development of technical and tactical qualities and those of all the physical qualities (Seo et al., 2015; Gorostiaga et al., 1999). Given the importance of the lower limb strength in handball, it seems interesting to analyze the influence of the Pc2P on the evolution of isokinetic muscle values (Crosier et al., 2008). Our hypothesis was that Pc2P may increase the maximum strength and power parameters of the flexor (Hamstring - H) and extensor (Quadriceps - Q) muscles of the knee joint. Methods 19 male handball players, all French or foreign international handball players, belonging to the Ligue 1 club Montpellier Agglomeration Handball (MAHB - France), participated in this study. Pc2P, with a duration of 8 weeks, included three distinct phases. Firstly, a recovery phase of 2 weeks, with 3 sessions of strength training per week, devoted to the lower limbs. Secondly, a phase of 4 weeks, with 2 sessions of lower limb weight training per week. Finally, a final phase of two weeks, with 2 sessions per week. An isokinetic test protocol on dynamometer Biodek System 3® was carried out before and after the Pc2P. The evaluation was performed on the dominant and non-dominant leg in concentric (60°.s-1 and 240°.s-1) and eccentric (30°.s-1) modality, in order to determine the peak torque (PT), average power (AP) and ratio, dominant and non-dominant leg (DNDR), agonist/antagonist (AAR) and combined (CR). Results At 60°.s-1, in concentric modality, the comparison of PT values, before and after Pc2P, shows no significant difference for Q. For H, we observed a significant increase ($p<0.001$) of PT on both sides. At 240°.s-1, in concentric modality, our results showed a significant increase (0.001)

EFFECT OF 3 VERSUS 3 SMALL SIDED HANDBALL GAME TRAINING ON AEROBIC CAPACITY AND ANAEROBIC ENDURANCE OF MALE HANDBALL PLAYERS

CHITTIBABU, B.1, WEBER, J.2

1: Annamalai University, Tamilnadu, India; 2: CAU, Kiel, Germany

Introduction Today handball is more dynamic and faster than ever before. During handball game players perform several high intensity repeated sprint bouts of short duration with partial rest (Póvoas et al. 2012; Sibila, Vuleta & Pori 2004) which is associated with good endurance capability and anaerobic endurance of players. Developing fitness through skill based conditioning is more suitable than traditional training. Small sided games are a type of skill based conditioning which combines both sports specific skills and fitness. Therefore, the aim of our study is to assess the effect of 3 versus 3 small sided handball game training on aerobic capacity and anaerobic endurance of male handball players. Methods Twenty four (24) male handball players were selected and randomly classified into two groups namely 3 versus 3 small sided handball training group (3 vs 3 = 12) and control group (CON = 12). Twenty four handball players were tested on aerobic capacity and anaerobic endurance before the start, at middle and after twelve weeks of training. The 3 versus 3 small sided handball training was performed three days per week for twelve weeks. To assess the training effect 2 × 3 repeated measure ANOVA on last factor repeated was performed. Results The result of our study showed that six and twelve weeks of 3 versus 3 small sided handball game training significantly improved aerobic capacity ($F=51.36$, $p=0.000$) and anaerobic endurance ($F=32.48$, $p = 0.000$) of handball players. Discussion The result of our study showed that 3 versus 3 small-sided handball game has large effect and which confirm that 8.66% improvement in aerobic capacity and anaerobic endurance by 6.74% improved after twelve weeks of training. Coutts and his colleagues (2010) clearly state that game based training improves both fitness (Chittibabu 2013) and skill. The improvement in VO₂ max is associated with changes in cardiovascular function and anaerobic endurance is enhanced through faster lactate removal and PCr restoration, thus enhancing power and force recovery (Bassett et al. 1991). It is concluded that 3 versus 3 effective in improving

aerobic capacity and anaerobic endurance of male handball players. References Póvoas SC, Seabra AF, Ascensao AA, Magaihaes J, Soares JM, Rebelo AN. (2012). *J Strength Cond Res*, 26, 3365-3375. CONTEMPORARY REFERENCE VALUES FOR PEAK OXYGEN UPTAKE IN HEALTHY EUROPEAN CHILDREN AND ADOLESCENTS

BUYS, R., TAKKEN, T., REYBROUCK, T., OBERHOFFER, R., GEWILLIG, M., HAGER, A., MUELLER, J.

KU Leuven

Background Cardiopulmonary exercise tests (CPET) are widely used for the assessment of cardiovascular and respiratory capacity during exercise. Ever since its introduction, CPET measures have been compared with a normal reference frame. Most available reference values are based upon older studies. However, times change and so do lifestyles. In that view, reference values should be regularly updated and validated. Furthermore, exercise capacity shows a large variability and thus reference values are ideally obtained from large samples of the population, which has often not been the case. Therefore the aim of this study was to obtain contemporary reference values for peak VO₂ and establish prediction equations for healthy boys and girls. Methods Between January 2000 and April 2015, 1580 healthy children (1010 boys; mean age 12.4 years; range 5-18) completed a maximal graded exercise test until exhaustion either on a bicycle or on a treadmill. Minute ventilation, oxygen uptake (VO₂), and carbon dioxide (CO₂) production were measured on a breath-by-breath basis and continuous electrocardiography was performed. Peak VO₂ was expressed in mL/min and mL/min/kg. Prediction equations based on sex, age, weight and height were calculated by means of regression analysis and cross-validated through concordance correlation coefficient determination and Bland-Altman analyses. LMS chart maker was used to provide age-related percentile curves. Results Multivariate regression analysis revealed age, sex and weight as statistically significant determinants of peak VO₂. Hence, following prediction equation was established and cross-validated: peak VO₂=44.5-218*sex+27.1*age+37.4*weight ($p\leq 0.001$; sex=0 for boys and sex=1 for girls). Finally, the distribution of peak VO₂ per kg body weight with age was described by percentile curves and reference values were established for boys and girls of less and more than 12 years old, separately. Conclusions Our study is the largest and most recent population-based study to provide sex-specific reference data and prediction equations for peak VO₂ for a West-European population of healthy children between the ages of 6-18 years.

A POST-SEASON SHORT DURATION MESOCYCLE FOR TAPERING IN WATER-POLO

BOTONIS, P., TOUBEKIS, A., PLATANOU, T.

University of Athens

A post-season short duration mesocycle for tapering in water-polo Petros G. Botonis, Argyris G. Toubekis, Theodoros I. Platanou Department of Aquatic Sports, School of Physical Education and Sports Science, University of Athens, Greece. Introduction In water-polo, although elite coaches' experience has been reported (Mujika, 2009), no scientific evidence exist regarding methods of effective tapering prior to a series of critical matches usually playing post-season. The aim of the present study was to examine the effectiveness of a four-week mesocycle, including an overloaded (week 1 and 2) and a reduced training load periods (week 3 and 4), on wellness, swimming performance and perceived internal training load (ITL) in water-polo players preparing for play-offs. Methods Eight national-level water-polo players (age: 25±7 years, body height: 181±5 cm, body mass: 84±7 kg) participated in the study. ITL was estimated using the session-RPE method and perceived ratings of wellness (e.g. fatigue, muscle soreness, sleep quality, stress level and mood) (Hooper & Mackinon, 1995) were assessed daily. Sport-specific performance was evaluated through 400-m and 20-m tests performed before (baseline) and after overloading training as well as at the end of reduced training load phases. Analysis of variance for repeated measurements on dependent samples was employed to detect differences between training phases. A Tukey post-hoc test was used for multiple comparisons. Correlation coefficient (r) was used to test the associations between changes (Δ) in performance variables and the respective changes in ITL, wellness, sleep quality, fatigue perception muscle soreness, stress level and mood state across the training weeks. Statistical significance was set at $p<0.05$. Results In week 3 and 4, ITL was reduced compared to week 1 by 19.0±3.8% and 36.0±4.7%, respectively ($p=0.00$ and $p=0.00$). Wellness was significantly improved in week 4 compared to weeks 1 and 2 ($p=0.00$). At the end of the mesocycle, swimming performance at 400-m and 20-m tests was improved compared to baseline (0.8±0.6% and 2.1±2.2%, respectively, $p<0.05$) and overloading training period (1.3±0.8% and 2.5±2.8%, respectively, $p<0.05$). High correlations were observed between the percentage reduction of ITL (week 4-1) and the respective changes in 20 m swim time ($r=0.88$, $p<0.01$), in fatigue perception, muscle soreness, stress levels and the overall wellness scores ($r=0.74-0.79$, $p<0.05$). Discussion The reduction of ITL improved the overall perceived wellness and sport-specific swimming performance of players. The abovementioned approach might be an effective training strategy in the lead-up to play-offs tournament providing useful and practical tool for screening changes in wellness and recovery status of the players. EFFECT OF STATIC AND DYNAMIC STRETCHING DURING A FULL WARM-UP ON ATHLETIC PERFORMANCE IN ATHLETES

BLAZEVICH, A.J., GILL, N.D., KVORNING, T., KAY, A.D., GO, A., HILTON, B., DRINKWATER, E., BEHM, D.

Edith Cowan University

Introduction Significant evidence indicates that static muscle stretching can acutely reduce muscle force/power production whilst dynamic stretching may increase it. However, study designs have not been appropriate in the majority of studies to determine whether muscle stretching affects performance when it is performed within a full, sports-specific warm-up (Behm et al. 2016). We aimed to determine the

effects of static and dynamic stretching during a 'sport-specific warm-up' on running, jumping, agility and flexibility performances in athletes. Methods Twenty men competing in running-based sports completed a familiarization and four weekly testing sessions. Using a randomized, cross-over design the subjects performed 5-s static passive stretches of lower limb muscles, 3x10-s static stretches, dynamic stretches (5 reps/leg, identical body positions to static stretches) or a non-stretch control condition within a warm-up (5-min general warm-up before stretch, and test-specific, progressive warm-up including maximal efforts after stretch). Researchers were blinded to the warm-up condition, and subjects nominated which condition they believed would yield best performance before the study (subject-level bias) as well as their perception of 'preparedness' (1-10 scale) after each warm-up condition. Results Eighteen of 20 subjects believed that dynamic stretching would yield best performances, however no between-condition differences ($p=0.23-0.99$) were detected in: (1) 5 m, 20 m or 10-20 m sprint times, (2) squat, countermovement or 3-step running jump heights, or (3) agility T-test time. Magnitude-based inference statistics showed a high likelihood of 'trivial' changes. Small and equal post-warm-up increases in sit-and-reach flexibility (1.9-2.4 cm, $p<0.01$) were achieved in the stretch conditions compared to no stretch. Subjects typically felt more prepared ($>5.2/10$) for testing when some stretching was performed (no stretch=3.9/10), with no differences between conditions. Discussion No stretch-specific effect on performance was observed when a warm-up protocol that included low-intensity exercise before muscle stretching was followed by a progressive, test-specific warm-up to maximum exercise intensity in athletes. Thus, although subjects felt better prepared for exercise, short- (5 s) or moderate-duration (30 s) static stretching or dynamic stretching had no group-level effect on performance when used in a full warm-up. Subject belief (i.e. subject-level bias) also did not influence test performances. Based on current and previous data, and contradictory to (some) current recommendations, muscle stretching appears not to influence physical performance when used as part of a full 'sport-specific warm-up' in athletes. MUSCLE METABOREFLEX: POSSIBLE EFFECT ON ARTERIAL BAROREFLEX FUNCTION AT REST

GELADAS, N.I., CHEROUVEIM, E.I., VRABAS, I.2

1:National and Kapodistrian University of Athens, Greece, 2:Aristotle University of Thessaloniki, Serres, Greece

Introduction Arterial baroreflex is a determinant of cardiovascular regulation both at rest and during exercise (Rowell and O'Leary, 1990). Furthermore, it has been shown that muscle metaboreflex activation during dynamic exercise may influence the arterial baroreflex sensitivity (BRS) (Ischihose et al., 2014). However, it is not known whether muscle metaboreflex activation via muscle blood flow restriction modifies per se or in combination of muscular contraction the BRS. The aim of this study was to investigate whether restriction of muscle blood flow affects the function of arterial baroreflex. Methods A group of 26 healthy subjects, aged 33 ± 2 yrs, participated in this study. Cardiovascular response, muscle and cerebral oxygenation were continuously recorded during a resting period of 10 minutes under two separate experimental conditions: (a) with thigh cuffs (C) inflated to 120 mmHg on both legs and b) without cuffs (NC). Furthermore, BRS (in ms/mmHg) was assessed by the sequence method using BeatScope software. Results Cuff inflation effectively reduced muscle oxygenation as indicated by the increase of $\Delta[Hb]$ (NC: -0.12 ± 0.21 μ M vs. C: 11.28 ± 1.15 μ M, $p<0.001$) and the decrease of Δ [difference between O₂Hb and HHb] (NC: 0.15 ± 0.44 μ M vs. C: -8.89 ± 1.07 , $p<0.001$). Muscle blood flow restriction did not affect the cardiovascular response, i.e. heart rate and arterial blood pressure, whereas BRS was significantly reduced (NC: 11.20 ± 0.57 ms/mmHg vs. C: 9.79 ± 0.57 , $p=0.009$). Furthermore, cerebral oxygenation was affected by muscle blood flow restriction. Specifically, $\Delta[Hb]$ was increased (NC: -0.24 ± 0.06 μ M vs. C: 0.35 ± 0.19 μ M, $p=0.004$) and Δ [difference between O₂Hb and HHb] was decreased (NC: -0.24 ± 0.06 μ M vs. C: 0.35 ± 0.19 μ M, $p=0.004$), whereas $\Delta[O_2Hb]$ (NC: 0.51 ± 0.15 μ M and C: 0.09 ± 0.29 μ M, $p=0.19$) and ΔTHB (NC: 0.25 ± 0.13 μ M vs. C: 0.50 ± 0.37 μ M, $p=0.54$) were not significantly affected. Discussion Muscle blood flow restriction via thigh cuffs inflation at 120 mmHg may not be enough to activate muscle metaboreflex pressor response at rest. However, the reduction of BRS indicates that a greater increase of external thigh pressure was probably required for a metaboreflex response to be exhibited. Interestingly, the reduction of muscle oxygenation at rest increases oxygen extraction at cerebral level, a phenomenon which may also contribute to the observed lower baroreflex sensitivity. OP-PM24 Indicators of Fatigue

SUBJECTIVE INDICATORS OF FATIGUE IN FOOTBALL - EFFECTS OF FATIGUE STATUS AND SUBJECT IDENTITY

NOOR, D., HECKSTEDEN, A., HOWLE, K., DUFFIELD, R., SKORSKI, S., MEYER, T.

Saarland University

Introduction Current athlete monitoring approaches in many sport settings use a mix of subjective and objective indicators of fatigue. Whilst, there is recent evidence to suggest subjective measures reflect training load with greater sensitivity and consistency than objective measures (1,2), the appropriateness of a fatigue indicator will ultimately be determined by its long-term diagnostic accuracy, along with its potential sources of variability and bias. Thus, this study aims to analyse the inter- and intra-individual variability of football players' subjective ratings of wellness during the seasonal competition phase. Methods 35 male football players (1st League Australia, 25.3 ± 4.8 y) participated in the study. Individual perceptual ratings of wellness (fatigue (F), sleep quality (SQ), muscle soreness (MS), stress (S) and mood (M)) were repeatedly collected during the competition phase of a football season using a previously published questionnaire (3). Individual's ratings were retrospectively classified into 'fatigued' and 'recovered' states according to recent physical load. Players were defined as fatigued after performing >30 match-day minutes and as recovered when they had >1 post-match rest/recovery day. A minimum of 6 observations per fatigue and subsequent recovery status was necessary to be included for analysis ($n=14$). Variability was then analysed using a mixed effects model (fixed factor: fatigue status, random factor: subject ID and fatigue status-by-subject ID interaction). Results The fixed effect of fatigue status was highly significant for all fatigue parameters ($p < 0.001$). The proportion of total variability attributable to fatigue status-by-subject ID was: W (40.7%), F (34.2%), SQ (19.4%), MS (21.8%), S (18.5%), and M (17.6%). Between-subject variability (random effect subject ID) was calculated to be redundant for F, SQ and W and very small for M (4.6%) and S (9.1%). Discussion The current study indicates that fatigue status-by-subject ID interaction ('individual response') explains a substantial proportion of variabil-

ity in subjective ratings of fatigue in elite football players. By contrast, between-subject variability in fatigued and recovered ratings was small. Thus, when longitudinally examining the fatigue status of a footballer it is relevant to consider inter-individual differences in the magnitude of fatigue induced changes in ratings of subjective wellness. INDICATORS OF FATIGUE IN FOOTBALL – EFFECTS OF FATIGUE STATUS AND SUBJECT IDENTITY

SKORSKI, S., HECKSTEDEN, A., RAUBER, C., WALTER, M., MEYER, T.

University of Saarland

Introduction Large variability has been reported for indicators of exercise induced physical fatigue (1,2). This obviously impedes on their diagnostic accuracy. However, despite the practical importance of monitoring fatigue, not much data about the sources of this variability is currently available. Therefore, this study aims to analyse the inter- and intra-individual variabilities in indicators of physical fatigue during in-season training phases in football players. Methods 41 male football players (4th League Germany, 26.5 ± 4.2 y) participated in the study. Within a period of 3 months in the regular football season venous blood samples (analysed for CK and UREA) and counter movement jump (CMJ) performances were collected repeatedly in 'fatigued' and 'recovered' states. Players were defined as fatigued after performing >2 training sessions within 48h and as recovered when they had at least 1 day off. Training load was documented throughout data collection. A minimum of 3 observations per fatigue status was necessary to be included for analysis ($n = 35$ included). Standard error of measurement expressed as a percentage of the groups mean score (coefficients of variation (CV)) for CK, UREA and CMJ was calculated. Variability was analysed using a mixed effects model (fixed factor: fatigue status, random factor: subject ID and fatigue status-by-subject ID interaction). Results CV for fatigued values was: CK: 52.3%, UREA: 14.6%, CMJ: 4.3%; and for recovered values: CK: 45.2%, UREA: 14.0%, CMJ: 4.5%. The fixed effect of fatigue status was highly significant for CK and UREA ($p < 0.001$) but not significant for CMJ ($p = 0.49$). The proportion of total variability attributable to subject ID was 37.9% for CK, 54.7% for UREA and 64.8% for CMJ. Fatigue status-by-subject ID interaction accounted for only 1.1% of total variability for CK and 0.5% for UREA. Discussion The current analysis indicates a high inter- as well as intra-individual variation in fatigue induced changes of CK, UREA and CMJ. By contrast status-by-subject ID interaction ('individual response') is negligible. Regarding the large between subject variability individualised interpretation using baseline measurements might lead to greater accuracy in the monitoring of the fatigue status in footballers. RELIABILITY OF A FATIGUE RESPONSE IN ELITE YOUTH FOOTBALL PLAYERS

FITZPATRICK, J.F., RUSSELL, M., HAYES, P.R.

Northumbria University

Introduction In football, reliable and time-efficient methods of player monitoring are desirable as the effects of prior football-specific exercise may dictate the programming of subsequent training loads. Therefore, this study aimed to assess the reliability of different methods of assessing the fatigue response to a standardised exercise bout. Methods In 12 elite youth football players and for two consecutive weeks, subjective ratings of wellness (fatigue, sleep quality, muscle soreness, stress and mood), indices of jump height (countermovement jump; CMJ, squat jump; SQJ, and drop jump; DJ-H), drop jump contact time (DJ-CT), drop jump reactive strength index (DJ-RSI), as well as locomotor profile recorded during a sub-maximal run, requiring players to complete a 20 m shuttle run at a speed of 12 km.h⁻¹, whilst wearing a 100-Hz tri-axial accelerometer (Kionix: KXP94, Minimax S4, Catapult Sports). Accelerometer data collected was analysed for PlayerLoad (PL) in the anteroposterior (Fwd), mediolateral (Side) and vertical (Up) planes with the percent contribution of each plane retrospectively analysed. Testing took place over four consecutive days, leading up to and following a standardised football training session including; a repeated sprint protocol, possession drills and small sided games. A magnitude based inference approach (>75% likelihood of the effect size; ES, being greater than or equal to ± 0.2 pre-post exercise) determined the effect of training. Using data collected 24 h post exercise for two consecutive weeks the reliability of the fatigue response was expressed as a coefficient of variation (CV; %) and intraclass correlation (ICC). Results Substantial changes 24 h post exercise existed for sleep quality, muscle soreness, total wellness, DJ-H, DJ-RSI and all locomotor profile variables except PL (ES -1.27 - 0.46). However, when comparing the response 24 h post exercise over both weeks of testing, a reliable fatigue response was only found for DJ-H (CV 7.0%, ICC 0.84), DJ-RSI (CV 8.6%, ICC 0.93), PL Fwd (CV 10.9%, ICC 0.85), PL Side (CV 6.1%, ICC 0.84), PL %Fwd (CV 5.1%, ICC 0.90) and PL %Up (CV 4.6%, ICC 0.76). Discussion Drop jump height, reactive strength index and a number of locomotor profile variables, in particular PlayerLoad Side and % Fwd were reliably able to detect a training induced fatigue response in elite youth football players. These specific variables could therefore be employed prior to training to assess residual fatigue in an applied environment.

DOES ACUTE FATIGUE AFFECT PLAYER LOAD DURING AN AGILITY TASK?

MARQUES, J.

Aspetar - Qatar Orthopaedic Sports Medicine Hospital

Introduction Accelerometers have been used to quantify deceleration (Nedergaard et al., 2014) and may be useful for monitoring neuromuscular fatigue (Buchheit et al., 2015). Whether they can be used to quantify fatigue-induced changes in loading during reactive agility tasks is unknown. Therefore, the aim of this study was to examine the differences in loading during an agility test (AT) before and after an acute bout of fatigue (AFT). Methods Seven male trained soccer players (mean \pm SD age: 26.1 ± 5 y, weight: 72 ± 8 kg, height: 174 ± 7 cm) were fitted with 100Hz integrated tri-axial accelerometers (Catapult S5, Catapult innovations, Canberra) at the scapulae (SCAP) and right (R) and left (L) ankle. Following a standardized warm-up participants performed a 20m maximal sprint and upon hearing an audio signal would decelerate, change direction (180°) and return to the start line. The audio signal was randomly provided at 1.0, 1.5 and 2.0s with players performing 2 repetitions for each time condition both pre- and post-AFT (12 in total). The AFT consisted of maximal 25m (2x12.5m) shuttle sprints interspersed with 20s rest. The test was ceased when a 5% decrement in sprint performance was reached. Load was measured using the player load variable (PL) and its tri-axial components. Repeated measures ANOVA was used to compare temporal differences across the AFT and the magnitude of the effects (ES) was calculated. A paired-sample t-test was conducted to examine differences in stride variables (e.g. number of steps and distance covered) between pre- and post-fatigue. Results A 5% sprint decrement ($p < 0.01$, ES: -

2.5) corresponded to average decrease in PL of 19.9, 23.3, and 17.3% ($p<0.01$, ES: 1.4-2.34) for SCAP, R and L. The AFT did not have a statistically significant effect on PL ($p>0.05$) during any of the agility tests (ES: trivial to small in all unit locations, 0.1-0.4). The vertical component of PL was 5 times higher at the ankles compared to SCAP. No changes were observed for stride variables ($p>0.05$). Discussion A 5% reduction in sprint performance was associated with a 4-fold larger reduction in PL, possibly due to reduced vertical stiffness (Girard et al., 2011). Our findings may support the use of accelerometers to monitor fatigue as well as quantifying player load during agility tasks. The use of accelerometers may also provide practical insight into the changes experienced during agility tasks. References Buchheit M, Gray A, Morin JB (2015). DIFFERENCES IN STRENGTH, POWER AND FATIGUABILITY BETWEEN ALPINE SKIERS OF FIS WORLD CUP AND EUROPEAN CUP

BOSIO, A., CARLOMAGNO, D., TORNAGHI, M., MANZONI, R., PANZERI, A., RAMPININI, E.

Mapei Sport Research Centre

Introduction Physical and technical abilities are important factors for alpine skiing performance. Races are high-intensity exercises of short duration (60-120s) requiring repeated high-force isometric and eccentric contractions (Ferguson, 2010). Aerobic capacity, strength, power and muscle fatigue are all considered crucial for success but limited information is available on top level and elite athletes (Neumayr et al., 2003). The aim of this study was to compare World Cup (WC) and European Cup (EC) skiers. Methods At the end of the preparation period, 26 male (12 WC and 14 EC) and 20 female (9 WC and 11 EC) skiers performed a peripheral knee extensors (KE) neuromuscular assessment, a counter-movement jump test (CMJ) and an incremental cycling test to exhaustion. Athletes also completed a specific test consisting of 3 sets of eccentric/concentric fixed workloads normalized per body weight with durations of 20, 60 and 90 s on a custom-built isokinetic horizontal leg press (LP). Decrement (baseline to after 90s LP) in CMJ and KE evoked twitches were used as a measure of fatigability. Comparisons between WC and EC were assessed for each gender. Data was analyzed using a magnitude-based inference approach. Percent differences ($\pm 90\%$ confidence interval) and Cohen's d are presented. Results An almost certain difference in age was found for males ($33 \pm 8\%$, 1.66) and females ($36 \pm 18\%$, 1.97). Differences in anthropometric, V O_2 peak and peak power output during incremental test were unclear in both genders (trivial/small d). CMJ height reported a very likely difference only in males after 90s LP ($11 \pm 8\%$, 0.90). CMJ absolute peak power differences were very likely ($12 \pm 9\%$, 0.89) after 90s LP for males and likely ($-7 \pm 9\%$, -0.55) at baseline, but unclear ($-3 \pm 10\%$, -0.22) after 90s LP for females. CMJ absolute peak force differences were unclear at baseline (males $5 \pm 9\%$, 0.30; females $5 \pm 8\%$, 0.42) and became very likely for males ($12 \pm 8\%$, 1.01) and likely for females ($11 \pm 10\%$, 0.81) after 90s LP. Evoked KE peak torque differences after 90s LP were very likely for both males ($73 \pm 60\%$, 1.00) and females ($57 \pm 96\%$, 0.51). Discussion Strength and power levels of WC and EC skiers were not substantially different at baseline in most of the investigated parameters. However, sizable differences between the two groups, detected after 90s LP, suggest lower levels of fatigability in both male and female WC skiers. The longer period of specific practice for WC skiers can be a factor explaining the present findings. References Ferguson RA. (2010). OPTIMISATION OF ASSESSMENT OF HEART RATE KINETICS FOR TRACKING FATIGUE-INDUCED PERFORMANCE DECREMENTS

NELSON, M., BELLENGER, C., THOMSON, R., DAVISON, K., BUCKLEY, J.

University of South Australia

Background: High volumes of physical training are required to generate physiological adaptations that improve performance, but can also lead to fatigue and temporary decrements in performance. Being able to quantify fatigue induced performance decrements to gain insight into an athlete's readiness to perform exercise could be useful for adjusting training and competition schedules. The maximal rate of increase in heart rate (rHRI) is assessed during 5 min of exercise, when transitioning from rest-exercise or from one workload to another, and has been shown to track fatigue induced performance decrements. Whether rHRI also tracks performance changes if assessed over shorter time periods has not been assessed. Method: Data from 15 athletes were collected prior to and after a period of heavy, fatigue inducing running training (HT). HR data was collected as R-R intervals pre-exercise and during 4 separate 5-min treadmill running tests: at 8 km/h (a workload primarily reflecting cardiac parasympathetic withdrawal; [rHRIPNS]), 10.5 km/h (rHRI10.5), and 13 km/h (rHRI13), and during a transition from 5 min of running at 8 km/h to 5 min of running at 13 km/h (a shift in intensity primarily reflecting cardiac sympathetic activation; rHRISNS). rHRI was the first derivative maximum of a sigmoidal curve fit to differing durations (1, 2, 3, 4 and 5 min) of the HR data for each treadmill test. Running performance was assessed using a 5 km treadmill time trial (5TT) prior to and after HT to provide an index of the effects of the fatigue-inducing HT on exercise performance. Results: Time to complete 5TT slowed from pre- to post-HT (Pre 1132.1 ± 121.9 sec, Post 1154.8 ± 122.0 sec, $P=0.002$). No method of assessment resulted in a change in rHRI from pre- to post-HT ($P=0.064$ to 0.931). Significant negative correlations were found for the 2 min assessment time in rHRIPNS ($P=0.04$, $r=0.38$) and the 1 minute assessment time during rHRISNS ($P=0.01$, $r=0.44$). Borderline significant correlations were found for the 3 and 1 min intervals during rHRIPNS (3 min: $P=0.05$, $r=0.36$; 1 min: $P=0.05$, $r=0.36$), and during the 3 and 2 min intervals during rHRISNS (3 min: $P=0.06$, $r=0.36$; 2 min: $P=0.06$, $r=0.37$). Discussion: Changes in 5TT performance were better tracked by changes in rHRI assessed over periods ≤ 2 min. This suggests that exercise induced fatigue primarily influences HR kinetics during the first minutes of exercise following a change in exercise intensity, with changes in performance being tracked most strongly when rHRI was modelled using the first 1 min of data during a transition from running at 8 km/h to 13 km/h. Assessment of readiness to perform exercise using a two-stage rHRI protocol with a short duration may provide useful information for informing training and competition schedules.

OP-PM10 Muscle Growth

THE EFFECT OF A FAILURE- VERSUS A SUBMAXIMAL BLOOD FLOW RESTRICTION PROTOCOL ON CHANGES IN NUMBER OF MYONUCLEI, SATELLITE CELLS AND MUSCLE SIZE

BRANKOVIC, R., BJØRNSEN, T., STÅLESEN, H., SUNDNES, J., BERNTSEN, S., PAULSEN, G., WERNBOM, M., RAASTAD, T.

University of Agder, Faculty of Health and Sport Sciences

INTRODUCTION: Low-load blood flow restriction resistance exercise (BFRRE) has been shown to induce a robust increase in muscle size, number of myonuclei and satellite cells (SC) when conducted to voluntary failure (1). However, the importance of BFRRE to failure on cellular adaptation has not been investigated. The purpose of the present study was to compare the effect of a failure- vs. a submaximal BFRRE protocol on the changes in number of satellite cells, myonuclei and muscle size over a period of two blocks with 7 BFRRE bouts (within 5 days), interspersed by 10 days rest. **METHODS:** Seventeen (18-45 yrs) untrained male participants had their legs randomly assigned to either failure- (FA; four sets to voluntary failure) or submaximal protocol (SU; 30-, 15-, 15-, 15 repetitions) using unilateral knee extensions at 20% of 1 repetition maximum (1RM) with 30 seconds rest between sets. BFRRE was conducted with partial blood flow restriction (100mmHg) induced by a pressure cuff with a 135mm pressure zone. Muscle biopsies were taken from both legs in m.vastus lateralis (VL) at baseline, during and 10 days post intervention. Biopsies were cut in 8 µm thick cross sections and stained against SC (NCAM + Laminin), myonuclei (DAPI) and fiber type (SC71 + dystrophin). Fluorescence microscope was used to quantify SC and myonuclei. Muscle thickness of VL was measured using ultrasound imaging. Strength was measured as 1RM in knee extension. **RESULTS:** The number of myonuclei increased significantly in both type 1 (mean \pm SD) FA: 12 \pm 16%; p=0.02 vs. SU: 17 \pm 16%; p=0.002, respectively) and type 2 fibers (FA: 20 \pm 17%; p<0.001 vs. SU: 23 \pm 13%; p<0.001, respectively) compared to baseline. Both groups increased the number of satellite cells significantly in type 1 (FA: 134 \pm 149%; p=0.03 vs. SU: 92 \pm 20%; p=0.003), but the number of satellite cells in type 2 fibers did not change in any of the groups. Muscle fiber area decreased in type 1 fibers in the failure leg (-10 \pm 16%; p=0.02), whereas it remained unchanged in the submaximal leg. Muscle thickness increased significantly in the failure leg (6.6 \pm 5.7%; p<0.001), while the submaximal leg had a tendency to increase (p=0.08) compared to baseline. 1RM in knee extension increased significantly in the failure leg (9 \pm 8%; p<0.001) and in the submaximal leg (11 \pm 7%; p<0.001) after 24 days post intervention. No group differences were observed in changes in number of myonuclei, satellite cells, muscle thickness or 1RM in post intervention. **DISCUSSION:** Both BFRRE protocols increased the number of myonuclei in type 1 & 2 myofibers, as well as satellite cells in type 1 myofibers. We did not observe any group differences in changes of myonuclei addition, satellite cell proliferation, muscle size or 1RM. Surprisingly, type 1 muscle fibre area was reduced in the failure leg, and the possible mechanisms warrants further investigations. **REFERENCES** (1) Nielsen JL, et al. MUSCLE ADAPTATION THROUGHOUT RESISTANCE TRAINING: INTEGRATED MYOFIBRILLAR PROTEIN SYNTHESIS MODULATION AND THE ROLE OF MUSCLE DAMAGE IN HYPERTROPHIC RESPONSES

DAMAS, F.I,2, PHILLIPS, S.M.2, LIBARDI, C.A.3, VECHIN, F.C.1, LIXANDRÃO, M.E.1, JANNIG, P.R.1, ROSCHEL, H.1, COSTA, L.A.R.1, BACURAU, A.V.1, SNIJDERS, T.2, TRICOLI, V.1, PARISE, G.2, UGRINOWITSCH, C.1

Introduction Muscle hypertrophy is one of the main outcomes from regular resistance training (RT) practice, but how it is modulated throughout training and the mechanisms regulating it are still obscure. It is known that intermittent increases in myofibrillar muscle protein synthesis (MPS) after RT bouts accumulate increasing muscle cross-sectional area (CSA). Indeed, studies have shown a qualitative agreement between MPS and hypertrophy, but, intriguingly we and others (1,2) recently reported that infusion-derived MPS, measured through hours after the first RT bout, did not align with the eventual hypertrophy after RT. Whether this have a physiological mechanistic reason as MPS was measured only after the first bout when, for example, muscle damage is highly pronounced burdening MPS to regenerate the tissue, or if it just a method issue (infusions trials, through hours only) of measuring MPS is not known. To explore this further, we used an integrated approach to measure MPS using deuterium-oxide and assessed muscle damage parameters, at the beginning (T1), 3wk into training (T2), and at 10wk of RT (T3). Methods Ten young men (age: 27 \pm 1 y; BMI: 23.6 \pm 1.0 kg·m $^{-2}$) were evaluated for muscle and fiber CSA by ultrasound at T1, T2 and T3 of RT. Integrated MPS analysis through D2O ingestion and muscle damage through Z-band streaming assessments were conducted before and 48h after the RT bout at T1, T2, and T3. Results Hypertrophy only occurred significantly at T3. 48h integrated MPS increased after the RT bout at the 3 evaluation weeks, but the increase was greater at T1 than T2 and T3 (similar values at T2 and T3). Z-band streaming increased at T1, was mildly attenuated at T2 and strongly reduced at T3. Increases in MPS at both T2 and T3, but not at T1, were correlated ($r\sim 0.9$, p<0.05) with hypertrophy. No significant correlations were found between muscle damage and hypertrophic responses. Discussion Integrated MPS assessed at different phases of RT allowed a more precise and encompassing measurement to capture its contribution to chronic hypertrophy. At T1 muscle damage is the highest and MyoPS do not correlate with hypertrophy, and at T2 and T3 damage is progressively attenuated reaching a minimal magnitude, but MPS is highly correlated with hypertrophy. These facts added to the absence of any correlations between damage and MPS or hypertrophy precludes any role for muscle damage in hypertrophic responses. References 1) Mitchell et al. (2014). SPARC PROTEIN EXPRESSION IN RESPONSE TO RESISTANCE EXERCISE TRAINING IN IMMOBILIZED RAT SKELETAL MUSCLE.

SON, J.S., KIM, J.H., KIM, H.J., SONG, W.

Institute of Sport Science, Seoul National University

Abstract Introduction: Secreted protein acidic and rich in cysteine (SPARC) is related to skeletal muscle atrophy.[1] Here, we investigated the effects of resistance ladder training on SPARC and examined SPARC expression during pre-training and following muscle atrophy in fast-type dominant muscle. We also hypothesized that resistance exercise training would improve muscle quality and alleviate increased SPARC protein expression in the rat atrophy model. Methods: Male Sprague-Dawley rats underwent resistance ladder training for 12

weeks and hindlimb immobilization for 7 days. Grip strength and muscle cross section areas were measured. SPARC protein expression in the plantaris, soleus, and serum after exercise training and immobilization were then analyzed. Results: Resistance training affects body weight ($P < 0.001$) and skeletal muscle mass (Soleus; $P < 0.01$, plantaris; $P < 0.05$, gastrocnemius medialis; $P < 0.05$) as well as the grip strength ($P < 0.001$) in normal and atrophy conditions. In the plantaris, muscle atrophy after hindlimb immobilization was alleviated by resistance training (31.82%). SPARC level of plantaris muscle was also alleviated in atrophy-induced rats after exercise ($P < 0.05$). Conclusion: We identified an association between resistance training and SPARC protein expression in atrophy-induced skeletal muscle. Furthermore, we demonstrated a possible compensatory effect for SPARC protein expression in skeletal muscle. Thus, SPARC would be a useful therapeutic target to overcome muscular atrophy and sarcopenia. Reference [1] Nakamura K, Nakano S, Miyoshi T, Yamanouchi K, Nishihara M. THE LEVEL OF 44/42 kDa MAPK PROTEIN IS CLOSELY RELATED TO THE FIBER TYPE COMPOSITION IN HINDLIMB SKELETAL MUSCLES OF SEDENTARY ADULT RATS AND IN THE SOLEUS MUSCLE DURING DEVELOPMENT

OISHI, Y.1, OGATA, T.2, OHIRA, Y.3, ROY, R.R.4

Laboratory of Muscle Physiology, Faculty of Education

Introduction: The relationship between the levels of mitogen-activated protein kinase (MAPK) and the phenotype of skeletal muscles is controversial (Dupont et al., 2011; Shi et al., 2008). To address this issue, we determined the relationship between the fiber type composition and the expression levels of 44/42 kDa MAPK protein in hindlimb muscles of sedentary rats. Methods: Fiber type composition based on immuno-histochemical staining and the expression levels of phosphorylated 44/42 kDa MAPK protein by Western blotting were analyzed in two experiments (Exp.). Exp. 1: the soleus (Sol), plantaris (Plt), and deep and superficial portions of the gastrocnemius (Gasd and Gass) muscles were excised from 10-week-old male Wistar rats and analyzed. Exp. 2: the Sol was excised at various times between 3-65 weeks of age and analyzed. Results: Exp. 1: in descending order, the percent fast fiber type composition was Gass (100%) > Plt (83%) > Gasd (71%) > Sol (14%) and the level of phosphorylated MAPK (relative to the Sol level) was Gass (30%) > Plt (27%) > Gasd (15%) > Sol (100%). Exp. 2: the Sol of 3-week-old rats contained ~40% fast fibers and this gradually decreased to 1.5% at 65-week time point. The expression level of phosphorylated 44/42 kDa MAPK protein (relative to the 3-week level) in the Sol gradually decreased from 3- to 65-weeks, i.e., 100, 51, 41, 33, and 1% at the 3-, 10-, 20-, 46-, and 65-week time points, respectively. Discussion: The data show that there is a close relationship between the levels of phosphorylated 44/42 kDa MAPK and the percent fast fiber phenotype across hindlimb muscles at the adult stage and in the soleus muscle during development. Thus these results suggest that the levels of phosphorylated 44/42 kDa MAPK may play a regulatory role in determining the fast fiber phenotype composition of rat skeletal muscles. EXPRESSION OF METABOLIC AND MYOGENIC FACTORS DURING TWO COMPETITIVE SEASONS IN ELITE JUNIOR CYCLISTS

FLÜCK, M., VALDIVIESO, P., JAECKER, V.C., HARMS, S.A., KONOU, T.M., TAPPE, K.A., SCHIFFER, T., FRESE, L., BLOCH, W., FRESE, S.

Balgrist Campus and University of Zurich, Zurich

Introduction It is not known whether the seasonal training patterns of endurance athletes produce corresponding adaptations of mitochondrial and myogenic processes and whether these relate to the metabolic load during exercise. Methods Ten male elite junior cyclists (mean \pm SE, 17.3 ± 0.15 years) were monitored over two seasons of preparation and competition. Aerobic performance and content of mitochondrial proteins (NDUFA9, SDHA, UQCRC1, COX4AI, ATP5A1, UCP3), myogenic regulators (myogenin, myoD, Tenascin-C) and myosin heavy chain (MyHC) were determined in m. vastus lateralis after the preparation and competition phase. Results Energy spent in training was comparable in the preparation and competition phase of the first season (9354 and 9825 MET/week) but decreased to 6800 MET/week at the end of the second preparation phase. Average mitochondrial protein content changed in anti-cyclical pattern to VO₂ peak, capillarisation, satellite cell and myonuclear number and correlated with the METs spent in the preceding training phase ($r=0.71$). Mitochondrial protein content was decreased after the first (-22%) and second (-45%) competitive phase, and increased (+21%) after the preparation phase. Tenascin-C (+34%) and myogenin (+166%) increased after the second preparation phase. Satellite cell number correlated with mitochondrial protein content ($r=-0.65$), as well as with slow and fast type MyHC content ($r=0.73$). Discussion The findings indicate a particular role of seasonal metabolic load for adjustments in muscle protein expression with training of elite junior cyclists and suggest that the capacity for mitochondrial biogenesis may become exhaust at the end of the competition phase when muscle enters a regeneration program. OP-BN11 Performance Tests

A NEW INSTANTANEOUS PERFORMANCE PARAMETER FOR ALPINE SKIING AND INDIVIDUAL SPORTS

GILGIEN, M.1,2, HAUGEN, P.1, REID, R.2

1: Norwegian School of Sport Sciences (Oslo, Norway), 2: Norwegian Ski Federation (Oslo, Norway)

Introduction To help gain insight into the intricacies of athlete performance in alpine ski racing, several measures of instantaneous performance have been proposed (Federolf, 2012; Supej, 2010). Since alpine ski races are held on inclined slopes, these instantaneous performance measures are usually expressed as functions of the instantaneous vertical altitude drop of the skier. (Supej, 2010) employed change in mechanical energy per altitude drop as a performance measure while (Federolf, 2012) employed difference in path length and speed per altitude drop as a performance measure. These measures are valid as long as the slope includes a vertical drop, but fail when the terrain is flat or uphill. Therefore, this study presents a new instantaneous performance measure that is independent of the slope inclination and therefore more applicable in the analysis of entire courses. Methods Athlete center of mass trajectories were cap-

tured by either video-based photogrammetry (Reid, 2010) or GNSS (Gilgien, 2015). Speed and path length were computed for each position along the trajectories (Reid, 2010). For each analyzed course, an average trajectory was calculated from the start to finish line based on all skier trajectories. A virtual plane was spanned normal to the average trajectory every 30 cm and was intersected with each of the single trajectories (Supej et al., 2011). At each intersection point, values for time, speed, path length and forces were interpolated and stored as a function of the distance from the start to the virtual plane in question. Results Instantaneous performance was expressed as time differences to the leader in the finish as a function of distance from start. To explain the differences in performance time, speed and path length were expressed as differences to the speed and path length values of the leader as a function of the distance from start. Forces were used in combination with time synchronized video of the skiing to explain the reasons for speed differences that occurred. Discussion Since GPS technology is applied in alpine skiing entire runs are tracked instead of some turns as it was common with video based photogrammetry. Hence, a larger range of terrain inclinations is included in the data sets, also flat and uphill terrain (Gilgien, 2015). The new performance parameter facilitates instantaneous performance analysis in any type of terrain and skiing discipline. The measures applies also to other individual sports like motorsport or cycling. References Federolf, P. (2011). J Sp Sci, 30, 1063-1068. Supej M, (2008). J App Biom, 24, 121-125. Reid R, (2010). CONSTRUCT VALIDITY OF THE ELEMENTARY MOTOR SPEED ABILITY

KRUG, J.1, WENZEL, U.1, VOß, G.2, KURTH-ROSENKRANZ, R.1, WITT, M.1

1: University of Leipzig (Germany), 2: Universum Academy Leipzig (Germany)

Introduction Rapid movements are connected with many terms, like quickness, speed, agility and power. Sheppard & Young (2006) reported on many studies of rapid complex movements. Later they derived for the training of agility and speed the influence of perception and anticipation. Voss, Witt and Werthner (2007) found the existence of elementary motor speed ability. These authors arranged reaction time, frequency speed, acyclic speed during reactive movements and non-reactive movements from defined preliminary tension or relative rest as categories of the elementary motor speed ability. Wenzel (2013) defined on the example of plantar flexion the speed with non-reactive movements as arbitrarily initiated. The purpose of this study was to inspect this theoretical construct of four elementary motor speed ability factors with an empirical data set using a confirmatory factor analysis (CFA). Methods First, with 78 students the reliability of 10 tests and 15 items were checked. Second, the construct validity with 214 students (95 women, age $M = 21.54$, $SD = 2.47$ and 114 men, age $M = 22.39$, $SD = 2.64$) were investigated, using the Maximum-Likelihood-Method (IBM SPSS Statistics, SPSS AMOS 21). The goodness-of-fit with the fit indices by Hu and Bentler (1999) were calculated. Results The valid model is based on simple and complex reaction speed, frequency speed and arbitrarily initiated speed. The global fit indices of the model are chi square = 86,08, df = 85, p = 0,447; CFI = 0,99; RMSEA = 0,009; SRMR = 0,071. The local fit indices were used for improvement of the model fit. Correlations were complemented on the residual variance based on the modification indices. All demands by Hu and Bentler (1999) are fulfilled for a good model fit. Discussion The reaction speed is integrated in a second order factor with the two factors simple and complex reaction speed. There is a middle correlation ($r = 0,31$) between the reaction speed and frequency speed (tapping tests). The arbitrarily initiated speed is an independent factor. For the reactive speed only the test drop jump could be used, therefore, a factor could not be proved. Further investigations into the validity of the elementary motor speed ability are in preparation. References Hu L, Bentler PM (1999). VALIDATION OF DATA COLLECTED WITH MOBILE METABOLIC MEASUREMENT SYSTEMS OVER TIME DURING ACTIVE COMMUTING

ROSDAHL, H., SALIER-ERIKSSON, J., SCHANTZ, P.

Swedish School of Sport and Health Sciences, GIH, Stockholm

Introduction With the aim of attaining valid descriptions of metabolic demands during active commuting in greater Stockholm new approaches have been used. We have previously reported evaluations of a mobile metabolic measurement system both in the laboratory (Rosdahl et al. 2010) and during simulated field conditions, including check of stability over time (Salier-Eriksson et al. 2012). However, to be confident with the validity of the metabolic data collected over time during mobile field conditions we have used new approaches. Methods During the period of data collection in the field with the mobile metabolic system (Oxycon Mobile, JLAB 5.21, CareFusion, Germany) this was controlled once by the manufacturer and 11 times in our own laboratory using a commercially available metabolic calibrator (Vacumed, syringe No.1750 and mass flow controller No. 17052, Ventura, CA, USA). On each occasion VO_2 and VCO_2 were checked between 1 - 4 L/min with the corresponding VE at 40-160 L/minute and tidal volume at 2 L. The calibration information (offset, gain and delay time) from the O_2 and CO_2 analyzers and volume sensor, being collected pre and post the field commuting tests, was analyzed. Additionally, the results of each experiment was critically examined in several means including an inspection of parallelism in heart rate and VO_2 . Results and Discussion As examined with the metabolic calibrator, all parameters (VO_2 , VCO_2 , RER and VE) measured by the mobile metabolic system were in general well within the boundaries of acceptance. Adequate stability of the O_2 and CO_2 analyzers and volume sensors for the time duration of each experiment was confirmed by small differences in the pre- and post-calibration factors. Based on two researchers' ocular inspections of heart rate and oxygen uptake recordings during active commuting, all but one were rated as generally parallel, and thus passed this type of check of the field measurements. Overall, the present investigation favors that data collected over time with a mobile metabolic system can be validated by a combination of metabolic calibrator measurements, analyses of calibration information and a critical examination of the variables from each single measurement. VALIDITY OF A MODIFIED LACTATE MINIMUM TEST, A MODIFIED REVERSE LACTATE THRESHOLD TEST, AND ESTABLISHED THRESHOLD CONCEPTS TO DETERMINE MLSS

WAHL, P., MANUNZIO, P., STRÜTT, S., VOLMARY, P., VOGT, F., BLOCH, W., MESTER, J.

German Sport University Cologne

Introduction The maximal lactate steady state (MLSS) is generally regarded as the foremost indicator of aerobic endurance. Most existing single-session tests use either fixed-[La] or inflection-point as determination criteria for MLSS. However, these criteria are arbitrary or empirically derived. The lactate minimum test (LMT) (Knoepfli et al. 2011) and the reverse lactate threshold test (RLT) (Dotan 2012) are the only single-session tests which are based on the physiologically founded lactate appearance-disappearance equilibrium concept that forms the basis for the MLSS test, as well. Anyhow, the originally suggested protocols show some limitations like the underestimation of the MLSS by the LMT or the missing determination of VO_{2max} during the RLT. The aim of the present study was to validate and compare modified-LMT-/RLT (mLMT/mRLT) and established threshold concepts (OBLA & mDmax) for the determination of MLSS. Methods 19 subjects performed a mLMT, mRLT, a step test (100W start, +20W every 3 min) and 3 or more constant-load tests of 30 minutes to determine power output at MLSS on a cycle ergometer. mLMT and mRLT both consisted of a first ramp test with the aim to determine VO_{2max} and to increase [La]. After a break, the initial load of the subsequent incremental or reverse segment was calculated individually and was increased or decreased by 10 W every 90 sec respectively. After the step test OBla and mDmax were determined. Results The mean difference to MLSS was $+2 \pm 7$ W for mLMT, $+5 \pm 10$ W for mRLT, $+9 \pm 21$ W for OBla and $+1 \pm 14$ W for mDmax, showing the lowest difference and the smallest limits of agreement for the mLMT. The correlation between power output at MLSS and mLMT was highest ($r=0.99$), followed by mRLT ($r=0.98$), mDmax ($r=0.95$) and OBla ($r=0.90$). The regression lines for all tests mainly run in parallel to the line of identity. VO_{2max} measured during the ramp tests was significantly higher compared to the step test (56.1 ± 7.5 vs. 53.5 ± 7.0 [mL·min⁻¹·kg⁻¹]). Discussion Due to the higher accuracy, especially of the mLMT, but also of the mRLT to determine MLSS compared to OBla and mDmax, we suggest both tests as valid and meaningful concepts to estimate power output at MLSS in one single test in moderately up to well trained athletes. Furthermore, mLMT/mRLT revealed higher VO_{2max} values, providing a more complete assessment of training status. Additionally our modified tests do not require detailed knowledge of subjects' training status compared to previous LMT- or RLT-protocols. References Dotan R. OP-PM16 Mixed session: Training & Exercise

THE EFFECT OF UNSTABLE RESISTANCE TRAINING ON MUSCLE POWER OF UPPER AND LOWER BODY

ZEMKOVÁ, E.1,2, JELEŇ, M.2, CEPKOVÁ, A.3, UVAČEK, M.3, HAMAR, D.1

Faculty of Physical Education and Sports, Comenius University in Bratislava

1: Department of Sports Kinanthropology, Faculty of Physical Education and Sports, Comenius University (Bratislava, Slovakia), 2: Sports Technology Institute, Faculty of Electrical Engineering and Information Technology, Slovak University of Technology (Bratislava, Slovakia), 3: Institute of Languages and Sports, Faculty of Mechanical Engineering, Slovak University of Technology (Bratislava, Slovakia) Introduction Power output during resistance exercises is more profoundly compromised under unstable than stable conditions when higher weights are lifted [1]. This effect is more evident for chest presses on the Swiss ball as compared to the squats on the BOSU ball [2]. The question remains whether these differences diminish after exercise regimens including unstable surfaces. This study evaluates changes in power during 8 weeks of the stable and unstable resistance training. Methods The subjects, divided into two groups, underwent resistance training either under stable ($n=14$, age 23.5 ± 2.4 y, height 182.7 ± 5.5 cm, weight 79.2 ± 8.4 kg) or unstable conditions ($n=13$, age 22.9 ± 2.2 y, height 179.6 ± 6.9 cm, weight 76.5 ± 11.0 kg) for a period of 8 weeks (3 sessions/week). Prior to and following 4 and 8 weeks of the training, they performed chest presses and squats on a stable support base and on an unstable Swiss ball and BOSU ball with previously established weight of 70% 1RM under stable conditions. The FITRO Dyne Premium system was used to monitor force and velocity and to calculate power. Results Mean power in the concentric phase of chest presses was significantly higher on the bench than on the Swiss ball before (427.8 ± 41.0 W and 379.5 ± 37.7 W, $p=0.029$) and also after 4 weeks of the training (431.5 ± 37.5 W and 392.0 ± 36.6 W, $p=0.037$). However, the values did not differ significantly after completing the training program (434.7 ± 39.7 W and 417.6 ± 40.4 W, $p=0.243$). Similarly, pre-training mean power was significantly higher during squats on the stable surface than on the BOSU ball (493.8 ± 48.4 W and 416.7 ± 42.0 W, $p=0.019$), whereas there were no significant differences in power after 4 (508.4 ± 44.1 W and 467.7 ± 37.9 W, $p=0.166$) and 8 weeks of the training (514.1 ± 42.5 W and 477.3 ± 39.8 W, $p=0.180$). Discussion Finding showed that significant differences in power under unstable and stable conditions prior to the training disappear after 4 weeks during squats and after 8 weeks during chest presses. This effect may be ascribed to a greater enhancement of power following the unstable as compared to stable resistance training in subjects practicing conventional resistance exercises. References 1. SHORT-TERM ADAPTATIONS TO TRADITIONAL AND DAILY UNDULATING KNEE EXTENSOR TRAINING IN STRENGTH-TRAINING EXPERIENCED WOMEN

PELZER, T., ULLRICH, B., PFEIFFER, M.

Johannes Gutenberg-University, Mainz

INTRODUCTION Strength training periodization has been successfully applied to various athletic populations over the last decades. Currently, traditional (TP) and daily-undulating (DUP) periodization models are most frequently discussed in literature but the more effective approach is yet to be determined. Conflicting study outcomes were hereby mainly due to methodological limitations such as insufficient control of mechano-biological exercise characteristics in the majority of studies (Toigo & Boutellier, 2006; Harries et al., 2015). For more accurate program comparison, this work analyzed TP and DUP during short-term knee extensor training with biofeedback-controlled

training stimuli. METHODS 19 strength-training experienced women performed 6 weeks of unilateral dynamic knee extensor training with 3 sessions per week, exercising 1 leg using TP and the contralateral leg using DUP. Intensities varied between 40%, 60%, and 80% of individual one repetition maximum (1RM) and were progressively adjusted in a weekly rhythm. To detect possible outcome differences, maximum voluntary isometric and isokinetic-concentric knee extensor strength (MVC), EMG-estimated neural drive of the M. quadriceps femoris (QF), and muscle architecture of the M. vastus lateralis (VL) and M. rectus femoris (RF) were analyzed by 2-factor ANOVA (time * training leg). RESULTS Significant temporal changes occurred for isometric (TP: 15%, DUP: 13%) and isokinetic-concentric (TP: 8%, DUP: 10%) knee extensor MVC and 1RM (TP: 18%, DUP: 23%). VL and RF-muscle thickness significantly ($P<0.05$) increased ranging from 12-20% for TP and from 13-19% for DUP respectively. Maximal voluntary QF-EMG-activity remained statistically unchanged in both legs. Importantly, no significant periodization effects occurred for any study outcome and similar effect sizes were calculated in both training legs. DISCUSSION According to current meta-analysis (Harries et al., 2006), our results indicate that TP and DUP were equally adapted to improve maximum QF knee extensor strength, EMG-estimated neural drive and VL + RF muscle architecture following 6-weeks of biofeedback-controlled dynamic strength training. Thus, mechanical alterations in the exercises force-velocity characteristics for instance might act as key neuromuscular adaptation triggers during intensive short-term training periods rather than stimuli periodization. IDENTIFICATION OF MAIN PHYSIOLOGICAL DEMANDS DURING A SIMULATED FIREFIGHTING EXERCISE

INWINKL, S.1, SEIBERL, W.1, HAHN, D.2, SCHWIRTZ, A.1

1 Technische Universität München (Germany), 2 Ruhr-Universität Bochum (Germany)

Introduction Firefighters wear full personal protection gear and a self-containing breathing apparatus (SCBA) when responding to an emergency situation. The SCBA delivers oxygen for 20-30 minutes. Air consumption and its relation to firefighting performance parameters have hardly been researched yet. Therefore, the purpose of this study was to investigate the physiological demands of a standardized German firefighting exercise and the relationship between firefighting performance and oxygen related endurance parameters. Methods 43 professional firefighters performed two firefighting tasks and a maximum treadmill testing. The treadmill test was done under laboratory conditions in order to establish maximum heart rate (HR), peak oxygen uptake (VO_{2peak}), ventilatory threshold (VT₁), and respiratory compensation point (RCP). Three physiological intensity zones were identified according to the HR values corresponding to VT₁ and RCP. A simulated firefighting exercise was performed twice by each subject with full personal protection gear and (1) SCBA to measure air depletion and (2) with a spirometry mask to measure the metabolic demands of the exercise. Then, optimal firefighting performance was defined as a model minimizing physical strain in terms of HR, duration of the exercise, and air depletion from SCBA. Based on this model, multiple regression analysis finally served to identify a small number of physiological variables that quantify overall individual physical fitness. Results The firefighting scenario with the spirometry mask required 13.8±2.1 min to complete, with an average oxygen uptake of 24.15±2.9 ml/min/kg and a heart rate of 80±7% of HRmax. The exercise with the SCBA required 13.3±2.2min to complete and heart rate averaged at 79±7% of HRmax. Firefighters spent 22±26% of testing time in Zone 1, 70±25% in Zone 2, and 8±16% in Zone 3. Air consumption averaged at 169±28 bar. Based on our model multiple regression identified three main factors that show a great influence on firefighting performance (70% of total explained variance): VO_{2peak}, ventilation and the time spent in Zone 1. Discussion We found that the highest energy contribution during the exercise came from the aerobic-anaerobic system (time spent between VT₁ and RCP). Based on the main factors influencing firefighting performance as identified by multiple regression we now recommend a periodic endurance screening for incumbents to establish sufficient VO_{2peak}, ventilation and ventilatory thresholds. The model we developed could also be used in planning individualized training programs to improve each firefighter's job performance. Contact stephanie.inwinkl@tum.de

ASSOCIATION BETWEEN PHYSICAL FITNESS CHARACTERISTICS AND SUCCESS IN BASIC MILITARY TRAINING IN LUXEMBOURGISH ARMY RECRUTS

BESENIUS, E., MALISOUX, L., THEISEN, D.

Luxembourg Institute of Health

The army of the Grand-Duchy of Luxembourg continuously recruits new candidates to enrol in basic military training (BMT). An increasing number of them do not manage to successfully finish their BMT and are released for medical or personal reasons. The purposes of this retrospective study were to define the extent of dropouts in military recruits during their BMT, as well as to determine possible risk factors for these dropouts. A total of 640 recruits were enrolled in the Luxembourgish army for a 4-month BMT between 2013 and 2015. Anthropometry (age, height, weight, body mass index), education level and physical fitness (ball throw, sit ups, standing broad jump, lying-start 24m sprint, push-ups, 2400m endurance run) were evaluated before BMT. Injuries leading to a dropout of BMT were assessed by the military medical doctor. Unadjusted logistic regressions were used to compute odds ratios (OR) and their 95% confidence intervals (95%CI) and to identify risk factors for dropping out of BMT, whatever the reason. Significance was accepted at the $p<0.05$ level. Participants (605 male and 35 female) were aged between 18 and 25 years (20.3±1.8 yr), were 176.6±7.5 cm tall and weighed 72.3±11.0 kg. Their body mass index was 23.1±2.8 kg/m². In total, 72% of the recruits did not have a high-school degree. Physical fitness testing revealed the following performances: 608±76 cm for 3 kg ball throwing, 64±10 sit ups in 2 min, 223±21 cm for the standing broad jump, 4.8±2.0 s for the sprint, 53±11 push-ups in 2 min and 11.2±1.2 min for the 2400 m endurance run. In total, 262 recruits (41%) dropped out of BMT, of which 92 (14%) due to medical reasons, 100 (16%) for personal motives, 58 (9%) because of failure in the final exams and 12 (2%) due to dismissal for disciplinary reasons. Being younger was associated with a higher risk for dropping out of BMT (OR=0.90; 95%CI=0.82 to 0.99; $p=0.03$). Height (cm) and weight (kg) were identified as protective factors with taller and heavier candidates having a lower dropout risk (Height: OR=0.98; 95%CI=0.95 to 1.00; $p=0.03$; weight: OR=0.98; 95%CI=0.97 to 1.00; $p=0.04$). Furthermore, a lower educational level (no high-school degree) was associated with a higher risk of dropout (OR=0.55; 95%CI=0.35 to 0.87; $p=0.01$). Finally, performance in the ball throwing (cm: OR=0.99; 95%CI=0.99 to 1.00; $p=0.02$), long jump (cm: OR=0.99; 95%CI=0.98 to 1.00; $p<0.01$), sprint (sec: OR=2.39; 95%CI=1.42 to 4.03; $p<0.01$) and endurance test (sec: OR=1.01; 95%CI=1.00 to 1.01; $p<0.01$) were also associated with BMT failure, the poorest performers being at higher risk. This study quantified the overall incidence of costly dropouts in young army recruits in Luxembourg. The analysis indicated that some characteristics related to physical fitness are associated with failure in BMT and represent a modifiable protective factor. Hence, prevention strategies, better medical surveillance and higher fitness readiness could decrease the rate of failure during BMT.

FIT AND FAT PARENTS: CAN MATERNAL EXERCISE OVERCOME THE DETRIMENTAL EFFECTS ON GLUCOSE TOLERANCE IN OFFSPRING OF A HIGH FAT EATING DAD?

FALCAO-TEBAS, F.1, ARCERI, C.R.1, KERRIS, J.P.1, MARIN, E.C.1, MCCONELL, G.K.1

Institute of Sport, Exercise and Active Living (ISEAL)

Introduction The 'Developmental Origins of Health and Disease' paradigm investigates how environmental cues early in life impact on long-term disease susceptibility, such as type 2 diabetes. Rat offspring sired by fathers fed a high-fat diet demonstrate impaired insulin secretion. On the other hand, maternal exercise improves glucose tolerance in adult rat offspring, but the underlying mechanisms remain unknown. Therefore, we investigated if adult offspring of fathers fed a high fat diet have impaired glucose tolerance, and if maternal exercise can overcome these detrimental metabolic effects. **Methods** Female Sprague-Dawley rat offspring were divided into 4 groups (n=8-10) according to their parents' treatment: normal chow fed fathers and sedentary mothers (N-S); high-fat fed fathers and sedentary mothers (HF-S); normal chow fed fathers and trained mothers (N-T); and, high-fat fed fathers and trained mothers (HF-T). Fathers consumed high-fat diet (42% energy as fat, 8 weeks) before mating. Meanwhile, mothers were exercised for 4 weeks before and 3 weeks during gestation, on a treadmill gradually reducing the duration and intensity (5 day/week, 60-20 min/day, 20-10m/min and 10-0° slope). At 24 weeks of age, an intraperitoneal glucose tolerance test (IpGTT) was performed, and blood glucose and plasma insulin were analysed. At 25 weeks of age, epitrochlearis and soleus muscles were dissected to evaluate insulin-stimulated 2-deoxyglucose (2DG) uptake and protein expression of glucose transporter 4 (GLUT4) with stain-free technology. Statistical differences were determined by repeated measures ANOVA. **Results** Although glucose tolerance was similar during the IpGTT among the four groups, HF-S pups had lower ($P<0.05$) insulin levels at 15 min which was normalised in HF-T pups. Basal and insulin-stimulated 2DG uptake in the soleus muscle was similar among the groups. However, in the epitrochlearis muscle, HF-S pups had lower basal and insulin-stimulated 2DG uptake, and this again was normalised by maternal exercise. GLUT4 expression in the HF-S pups was lower but not significant (-18%, $P>0.05$), however, HF-T pups had augmented GLUT4 compared with HF-S (+38%, $P=0.05$). **Discussion** Paternal high-fat diet impairs insulin secretion and both basal and insulin-stimulated glucose uptake in the epitrochlearis muscle of adult offspring. In most of the outcomes measured, maternal exercise protects adult offspring against the negative effects of paternal high-fat diet, indicating a healthier phenotype.

SUPERVISED PHYSICAL ACTIVITY DURING PREGNANCY LOWERS FETAL HEART RECOVERY TIME AFTER MATERNAL EXERCISE.

ROLDAN, O.1, PELAEZ, M.2, MOYER, C.3, BARAKAT, R.1

1Technical University of Madrid (Spain). 2Atlantics European University (Spain). 3Bridgewater College (USA)

INTRODUCTION Aerobic exercise influences cardiac autonomic nervous system (ANS) function in adults, seen as lower resting heart rate and heart rate recovery post-exercise (1). Intrauterine life could be affected by maternal habits during pregnancy (2). Recent research has reported improved ANS function in fetuses of active pregnant women (3,4). The aim of this study is to evaluate fetal heart adaptations due to enhancement of the fetal ANS as a result of maternal exercise. **METHODS** A randomized controlled trial (ID: RCT, NCT01723293) enrolled 81 pregnant women in two study groups. All participants signed an informed consent. The study was approved by the Clinical Research Ethics Committee University Hospital of Fuenlabrada (Madrid). The exercise group (EG n=43) received a supervised physical activity program(PAP) three times a week from 9-11 to 37-39 weeks gestation (5). The control group (CG n=38) did not receive any supervised PAP. All women were tested between 34-36 weeks gestation using two walking tests of three minutes each: 40% maternal heart rate reserve(MHRR) and 60% MHRR (4). Fetal heart rate (FHR) at rest and fetal recovery time (FRT) post-exercise in minutes/seconds (m/s) were recorded. **RESULTS** FHR at rest was similar in both groups 140.88 ± 9 EG vs 141.95 ± 7.35 CG ($p>.05$). FRT after 40% test was: $2m15s\pm 3m2s$ EG vs $7m6s\pm 5m27s$ CG ($p<.001$). FRT after 60% test was: $3m\pm 4m$ EG vs $9m 25s\pm 7m33s$ CG ($p<.001$). **DISCUSSION** Results show a faster recovery in fetuses of participants in EG, which could be an effect of the PAP performed during pregnancy (3). These fetuses received a training effect similar to that seen in trained adults. Further research in this field should be carried out to discover more evidence about the influence of exercise on fetal ANS development and its possible maintenance in the newborn's life. 1. OP-BN03 Motor Learning & Control

IMPROVED RETENTION PERFORMANCE AFTER VARIABLE PRACTICE COMES IN LINE WITH AN INCREASED ALPHA BAND POWER OVER THE PREFRONTAL CORTEX

THÜRER, B., STOCKINGER, C., STEIN, T.

Karlsruhe Institute of Technology

Introduction It is widely accepted that variable practice enhances the motor performance after a period of consolidation (Shea & Morgan, 1979). This effect could be explained by cognitive demanding processes in the prefrontal cortex which potentiate subsequent memory consolidation (Kantak et al., 2010). However, it is still unknown which neural processes lead to the enhanced motor performance. The aim of this study was to investigate the electrophysiology of learning related frequency bands over prefrontal areas in a motor adaptation task under variable practice conditions. **Methods** Subjects (n=24) were equally distributed in two groups (blocked, random) and performed goal-directed arm reaching movements handling a robotic device. Both groups performed a similar schedule over two consecutive days containing a familiarization and training block on day 1 (each 148 trials) and a retention block on day 2 (32 trials). During the

training block, subjects' movements were perturbed by a viscous curl force field with three gradations (10, 15, 20 Ns/m) in either blocked or random order. In the retention block, the force field was consistent at 15 Ns/m. We recorded hand-trajectories to quantify subjects' motor performances while adapting to the force field. Electroencephalography (EEG) was collected using 32 active-electrodes. After artifact correction, the percentage power of theta (4-7 Hz), alpha (8-13 Hz), and gamma (60-85 Hz) bands as well as theta-gamma phase-amplitude coupling (Canolty et al., 2006) were computed during movement execution. Statistical analyses were done using permutation testing. Results The kinematic data exhibited a significant interaction ($p=.037$; $p_{Eta^2}=.18$) between time (training, retention) and group revealing an increased performance improvement for the random compared to the blocked group. Furthermore, EEG alpha band power during movement execution showed a significant time and group interaction ($p=.047$; $p_{Eta^2}=.17$) indicating an increased alpha power during memory retrieval for the random group. Discussion This is the first study investigating the consolidation of variable practice in a force field adaptation task using EEG. The results show a positive effect of variable practice on motor performance which comes in line with an increased alpha band power over prefrontal areas. This supports previous hypotheses (Kantak et al., 2010) that the benefit of variable practice is facilitated by cognitive processes in the prefrontal cortex. CHANGES IN INTRACORTICAL INHIBITION IN RESPONSE TO BALANCE TRAINING

MOUTHON, A.1, WEISSBAUM, P.1, BRUNETTI, L.1, RUFFIEUX, J.1, TAUBE, W.1

University of Fribourg

Introduction The adequate development of intracortical inhibitory processes seems crucial for an intact motor control. With respect to balance, it was previously shown that healthy adults, both young and old, decrease short interval intracortical inhibition (SICI) when they perform challenging postural tasks (Papegaaij et al., 2015). However, the level of SICI is generally lower in elderly, who – at the same time – display worse balance skills than young subjects (Papegaaij et al., 2014). Therefore, we asked the question whether improvements in postural control due to balance training are accompanied by increased intracortical inhibition when tested during the performance of challenging postural tasks. Methods For this purpose, a training group (TG, practiced 6 trainings of 1 hour on a movable platform, $n = 13$) and a control group (CG, $n = 13$) were measured with transcranial magnetic stimulation (TMS). Two pulses with an interstimulus interval of 2.5ms were elicited in order to assess SICI during three postural tasks: standing, standing on a movable platform that was partly secured with elastic straps (straps), or that was freely moving (free). During each postural task, 20 single and 20 paired pulses were elicited by TMS in the soleus (SOL) and tibialis (TA) muscles. Results The TG significantly improved the time in balance by 80% after the training, whereas the CG increased the time in balance by 21%. The SOL did not reveal significant main effects or interactions for SICI, whereas the TA, showed significant increase of SICI by 22% for the TG abut a reduction of 12% for the CG: main effect of POSTURAL TASKS ($F_2, 48 = 24.6$; $p < 0.001$), and TIME x GROUP interaction ($F_1, 24 = 5.9$; $p = 0.02$). The increase in balance performance was correlated to an increase in intracortical inhibition ($r = 0.478$, $p = 0.021$) in the TA muscle. Discussion The purpose of this study was to evaluate whether balance training induced changes in postural control are accompanied by increased SICI. In summary, two weeks of balance training significantly improved postural skills in young adults. At the same time, an enhancement of SICI was observed in the TA and was correlated with the improvement in balance performance. This is an important finding, as it shows for the first time that neural adaptations induced by balance training were correlated with enhanced intracortical inhibition. This suggests that intracortical inhibitory processes may play an important role in the control and adaptation of upright posture. CARDIORESPIRATORY EFFECTS OF COMBINING TRANSCUTANEOUS SPINAL STIMULATION AND ROBOT ASSISTED WALKING: A CASE STUDY.

FLEMING, N., DONNE, B., MAHONY, N.

Trinity College Dublin

Introduction Previous research has demonstrated that spinal control of locomotor patterns can be up-regulated by assisted walking or spinal stimulation. However it remains to be elucidated if a combined approach may enhance function in spinal cord injured individuals. The current case study examined the effect of combining transcutaneous spinal stimulation with robot assisted walking on cardiorespiratory measures of exercise performance in a spinal cord injured individual. Methods The participant (39 year old male; height 1.81m, mass 84kg) with spinal cord lesions at T9 and L1 vertebral levels, had been assessed clinically as motor and sensory complete (ASI A). Test sessions of 60 min robot assisted walking were performed on three consecutive days using an exoskeleton (EKSO bionics). Each session included 4 by 15 min of walking with 5 min of seated recovery between exercise bouts. Electrical current was delivered transcutaneously to the spinal cord at the level of T10 (30Hz) and C01 (5Hz) during 2 of the 15 min exercise bouts in each session. This resulted in the completion of 12 by 15 min exercise bouts (6 with and 6 without stimulation). Cardiorespiratory data were collected via a portable metabolic analyser (Cosmed K4b2); hip and knee motor torque data were collected from the exoskeleton throughout all sessions. Data averaged over 3 min increments within each 15 min exercise bout were statistically compared using a 2-factor repeated measures ANOVA (time by stimulation). Results Robot assisted walking resulted in a mean VO_2 of $12.3 \pm 1.5 \text{ mL.kg}^{-1}.\text{min}^{-1}$. The addition of spinal stimulation to robot assisted walking resulted in a significant increase in VO_2 ($14.7 \pm 1.5 \text{ mL.kg}^{-1}.\text{min}^{-1}$, $F=35.6$, $P<0.01$). Heart rate was also significantly greater with combined spinal stimulation and robot assisted walking (128 ± 10 vs. $107 \pm 8 \text{ beats}.\text{min}^{-1}$, $F=32.2$, $P<0.01$). Both VO_2 and heart rate significantly increased during the course of the 15 min exercise bout ($F=5.8$, $P<0.01$; $F=11.6$, $P<0.001$, for VO_2 and heart rate, respectively). Knee torque data were consistently lower throughout the 15 min exercise bouts with stimulation, however this result was not statistically significant. Both left and right knee torque data significantly increased throughout the 15 min exercise bouts ($F=3.2$; $P<0.01$ for left; $F=3.1$ $P<0.05$ for right). Discussion The addition of transcutaneous spinal stimulation significantly increased metabolic and cardiovascular cost associated with robot assisted walking in a paraplegic individual. No significant differences in hip or knee joint torque data were observed. Further research is therefore required in order to establish what is causing the increased energy cost and whether this effect is consistent across a group of spinal cord injured individuals.

INFLUENCE OF MOTOR UNITS NUMBER ON TORQUE STEADINESS IN YOUNG AND OLDER ADULTS

BAUDRY, S., JOHANSSON, J., DUCHATEAU, J.

Université libre de Bruxelles

Introduction. A motor unit (MU) is considered as the elementary unit of motor control that consists of a motor neurone, its axon and the muscle fibres it innervates. The number of functioning MU has been reported to decrease with ageing, contributing to the age-related decrease in maximal force capacity (2). However, the influence of MU number on motor control, especially during fine motor tasks such as producing a constant torque as steady as possible, has not been directly investigated, even though a simulation study suggests that it should not be an influential factor in a hand muscle (1). The present work investigated the relation between MU number and torque steadiness during submaximal isometric contractions in young and older adults. Methods. MU number estimation (MUNE) in tibialis anterior was computed with the spike-triggered averaging technique of surface electromyogramme (sEMG) from concurrent intramuscular MU recordings in ten young (27.4 ± 5.4 yrs) and eleven older adults (70.8 ± 5.6 yrs). For each subject, at least ten MU was recorded for a total of 113 MU in young and 123 MU in older adults. The MUNE was calculated as the ratio of the amplitude of the maximal muscle compound action potential and the averaged amplitude of MU action potentials recorded by sEMG (Brown et al. 1988). The coefficient of variation (CV) for torque, used as an index of torque steadiness, was measured during isometric contraction of ankle dorsiflexor muscles performed at 5, 10, 15 and 20% of maximal dorsiflexion torque. Results. The maximal dorsiflexion torque was significantly greater in young (57.9 ± 15.9 N.m) than older adults (38.2 ± 14.3 N.m; $p = 0.010$) whereas the CV for torque was significantly lesser in young than older adults ($p=0.002$). MUNE was greater in young (172.2 ± 20.2) than older adults (90.7 ± 18.9 ; $p<0.001$) and was negatively associated with CV for torque at 5% contraction intensity but only in older adults ($r^2 = 0.43$; $p = 0.040$). Discussion. The results confirm that MU number in tibialis anterior decreases with ageing (2) whereas torque steadiness was significantly reduced in older adults. The data further show that the number of MU may influence the ability to produce constant torque as steady as possible during low-torque dorsiflexion contractions in older adults. In addition to other age-related changes within the neuromuscular system, this study suggests that the decrease in MU number likely contributes to alter performances in fine motor tasks performed with leg muscles in old adults. WOBBLE BOARD TRAINING IMPROVES MODULAR CONTROL OF LATERAL LANDING

OLIVEIRA, A., SILVA, P.B., MRACHACZ-KERSTING, N., KERSTING, U.G.

Aalborg University

Introduction High occurrence of sports injuries when landing from a jump may be a result of poor motor coordination, which may influence landing technique and energy dissipation. It has been suggested that balance training reduces injury risks by improving motor coordination. However, little is known about changes in motor coordination during landing following balance training. The aim of the present study was to investigate the effects of balance training on the modular control during lateral landing. Methods Twenty young adults were assigned to a control (CG = 9) and a training group (TG = 11). Both groups performed maximum effort lateral jumps, single-leg landing with their dominant limb on a force platform. The TG enrolled in a 4-week balance training program, whereas the CG kept their normal activities. We recorded surface electromyography (EMG) from 12 muscle of the dominant limb during lateral landing. We segmented EMG data from -100 ms prior to initial foot contact to 100 ms after the hip reaching its lowest position during load absorption. We applied non-negative matrix factorization (NMF) on the concatenated EMG from all subjects pre and post intervention. From NMF we extracted motor modules and activation signals describing the muscular activation of all subjects from each group. From the motor modules, we computed the similarity between pre- and post-tests. Relative weighting (Rw) for each muscle within one module was expressed as a percentage of the primary muscle defined as the one with the highest amplitude. The sum of Rw per module was used to provide a measure for module organisation. For activation signals, we computed the inter-subject variability (ISV) of the curves by computing coefficients of variance. Results Six motor modules were sufficient to reconstruct the original EMG datasets. Four modules were related to specific biomechanical sub-tasks: initial contact, load absorption, body deceleration and ankle stability. Pre-to-post test similarity between motor modules for CG was 0.76 ± 0.23 and for TG it was 0.70 ± 0.31 . The Rw for CG was $42 \pm 19\%$ and $42 \pm 20\%$ pre and post the intervention, respectively. For TG, Rw was reduced by ~25% (from 43 ± 21 for pre- to $30 \pm 15\%$ post-training). The ISV for the CG was increased ~9% from $82 \pm 10\%$ to $89 \pm 10\%$ from pre- to post-test, whereas the TG showed a reduction of ~12% from $80 \pm 10\%$ to $70 \pm 8\%$, respectively. Discussion The reduced similarity and Rw for motor modules for TG suggests a reorganization of muscle weightings after balance training. The weighting within one module appeared more concentrated on one or few muscles rather than distributed across each module. Moreover, the activation timing was more consistent across TG subjects after balance training. These results may reflect improvements in neural strategies for landing. In conclusion, balance training may improve motor coordination by reorganizing modular organization and temporal properties of muscle activation during landing. e-mail: oliveira@m-tech.aau.dk

Oral presentations**OP-PM79 Regeneration: Mixed Session****WHOLE-BODY COLD WATER IMMERSION AS A RECOVERY TOOL IN ELITE OLYMPIC WEIGHTLIFTERS**

SCHIMPCHEN, J., WAGNER, M., MEYER, T.

Saarland University

Introduction: Training and/or competing multiple times per day often induces excessive amounts of stress in athletes. This might result in temporary impairments in performance due to a variety of factors. Hence, the aim of the study was to investigate whether whole-body cold water immersion following intensive training sessions can be a useful recovery tool for elite Olympic weightlifters. Methods: Seven male members (25 ± 4 y) of the German national Olympic weightlifting team participated in the study. A randomized cross-over design was employed, consisting of two four day phases separated by a ten day wash-out period. In both phases, athletes underwent a total of five high-intensity training sessions, which were immediately followed by either a cold water immersion protocol (CWI) or a control protocol (CON). CWI consisted of a single bout of 10 consecutive minutes, during which the athletes were seated and immersed up to their

neck in water at between 12°-15° C, while CON consisted of 10 min of passive recovery in the same body position. A snatch pull movement at 85% and 90% of each athlete's individual snatch 1 RM served as a sport-specific performance test and was executed before and after both phases. Maximal barbell velocity during the pull was recorded. Throughout data collection, venous blood samples were collected from the athletes and subjective ratings of general physical and mental fatigue and recovery were assessed using a questionnaire. Results: Physical performance at either snatch pull intensity (85% 1RM: P=0.94; 90% 1RM: P=0.25) did not differ significantly between CWI and CON (condition x time). While questionnaires revealed a significant decline in ratings of overall recovery (P<0.001) and a significantly higher rating of overall stress (P=0.03) over time, there were no significant differences between conditions (P=0.14; P=0.98). Similarly, neither of the analyzed blood parameters changed significantly between conditions over time (CK: P=0.53; Urea: P=0.43; Cortisol: P=0.59; Testosterone: P=0.53; T:C ratio: P=0.69). On an individual level, responses to CWI varied considerably between subjects. Conclusions: In general, CWI did not prove to be an effective tool to enhance recovery in elite Olympic weightlifters over a three day intensive training period. However, even though the group was rather homogeneous with regard to performance, there were considerable inter-subject differences in their response to CWI. While some athletes improved performance and subjective well-being, others saw a decline in both parameters. Based on this data, it seems difficult to generalize the usefulness of CWI even within a homogenous athletic population. It appears that athletes are best advised on a case-by-case basis.

ADDING FISH OIL AND NATURAL ANTIOXIDANTS TO WHEY PROTEIN IMPROVES ECCENTRIC-EXERCISE RECOVERY IN SOCCER PLAYERS

PHILPOTT, J.D., DONNELLY, C., WALSHE, I.H., DICK, J., MCKINLAY, E., GALLOWAY, S.D., TIPTON, K.D., WITARD, O.C.

University of Stirling

Introduction The physical demands of soccer match-play is known to involve changing speed and direction, repeated sprints and explosives jumps, that predominantly requires eccentric type muscle contractions. Such movements often result in the phenomenon termed muscle damage. Protein feeding has been shown to preserve the functional capacity of skeletal muscle after eccentric exercise. Since fish oil derived n-3 polyunsaturated fatty acids (n-3PUFA) exhibit anti-inflammatory properties, combining ingestion of fish oil with protein may facilitate recovery. Therefore, the primary aim of the present study was to assess the influence of 6 wk supplementation with a juice-based antioxidant-rich drink containing a combination of n-3PUFA, whey protein and vitamin D on muscle function and soreness, inflammation and soccer performance during exercise recovery. Methods Competitive soccer players (n=27) were assigned to one of three conditions. Drink-A contained n-3PUFA (550 mg DHA, 550 mg EPA), whey protein (15 g) and vitamin D (3 µg). Drink-B contained whey protein (15 g) and vitamin D (3.9 µg) and Drink-C was an isocaloric carbohydrate control. Eccentric exercise consisted of 12 sets of unilateral knee extension/flexion contractions on both legs separately. Statistical analyses included conventional p-value and magnitude-based inferential approaches. Results Eccentric exercise impaired maximal force and increased ratings of muscle soreness (p<0.05). Post supplementation, blood %n-3PUFA/total PUFA was greater in Drink-A (36 ± 6) vs. Drink-B (24 ± 3, p<0.05) or Drink-C (23 ± 2, p<0.05). Maximum force loss during recovery tended (p = 0.10) to be less in Drink-A (-19 ± 22%) vs. Drink-C (-30 ± 10%). Muscle soreness (dominant leg), expressed as AUC during 72 h exercise recovery, tended to be less in Drink-A (791 ± 549 mm × 72 h) vs. Drink-B (1403 ± 779 mm × 72 h, p=0.08) and Drink-C (1298 ± 621 mm × 72 h p=0.10). The blood concentration of c-reactive protein tended (p=0.09) to be lower in Drink-A (AUC: 42 ± 11 mg/L × 72 h) vs. Drink-C (AUC: 83 ± 42 mg/L × 72 h, p < 0.05). Drink-A elicited a very likely (79-96%) beneficial effect on agility t-test performance vs. Drink-B and Drink-C. Discussion A juice-based antioxidant-rich drink, containing n-3PUFA, whey protein and vitamin D, appears to mediate a reduced feeling of muscle soreness after eccentric exercise and translates into improved muscle function and soccer-specific performance during acute recovery. Hence, the benefit of whey protein ingestion to exercise recovery may be enhanced by the addition of n-3PUFA and natural antioxidants in competitive soccer players. The present study was funded by Smartfish Ltd. Contact j.d.philpott@stir.ac.uk

MODERATE VOLUME, HEAVY-LOAD STRENGTH TRAINING, IN COMBINATION WITH PROTEIN SUPPLEMENTATION. EFFECTS ON MUSCLE MASS, STRENGTH AND FUNCTION IN FRAIL ELDERLY SUBJECTS.

AAS, S.N., NORDENGEN, A.L., KAASHAGEN, M., BENESTAD, H.B., RAASTAD, T.

Norwegian School of Sport Sciences

Introduction Low muscle mass and muscle strength (sarcopenia) is associated with reduced daily life function, in particular after the age of 80. Strength training and sufficient protein intake may be effective counter-measures [1]. Our objective was to investigate the effects of a high intensity, moderate volume strength-training regime, combined with protein supplementation, on muscle mass, strength and function in frail elderly individuals. Methods Twenty-two elderly subjects ($\sigma = 7$, $\varphi = 15$, age: 84.8 ± 5.6 yr) were randomized to two groups, one performing strength training three times a week for 10 weeks, and with a supplement of 2 x 17 grams of milk protein daily (ST+PRO), and a control group (CON). Training sessions were performed in subgroups of three subjects and lasted 30 minutes. Exercises included step up, leg press, knee extension (KE) and adapted one leg squat (1-3 6-12 RM sets). Prior to randomization, leg lean mass was measured by dual-energy X-ray absorptiometry (DXA), and muscle strength by KE 1RM and IMVC (isometric maximal voluntary contraction). Sit-to-stand x 5, stair climbing, and habitual gait velocity were tested to assess functional status. 24-hour diet recalls were conducted to assess nutritional status and monitor the impact of supplements. Results Leg lean mass increased in ST+PRO (0.7 ± 0.3 kg, $p < 0.01$), but was unchanged in the CON group (0.1 ± 0.3 kg). The ST+PRO group improved 1RM KE strength and IMVC force by $23 \pm 15\%$ and $20 \pm 11\%$, respectively, again with no changes in CON. In addition, IMVC force at 100 ms improved only in ST+PRO, by $22 \pm 22\%$. ST+PRO improved sit-to-stand x 5 ($10 \pm 13\%$), stair climbing ($11 \pm 12\%$) and habitual gait velocity ($7 \pm 10\%$), whereas no significant changes were detected in the control group. The changes in ST+PRO were significantly different from CON for all tests ($p < 0.05$), except for sit-to-stand x 5 ($p = 0.12$). Protein intake increased from 0.91 to 1.22 g/bm/day in ST+PRO ($p < 0.05$), and did not change in CON. Discussion These results show that high-intensity strength training performed 30 minutes three times per week for 10 weeks was sufficient to elicit improvements in strength and function, as well as muscle hypertrophy, in elderly frail individuals. High-intensity, moderate volume strength training is therefore suggested as an effective and practical low-cost strategy to prevent and treat sarcopenia in old people. 1.Chale, A., et al., J Gerontol A Biol Sci Med Sci, 2013. 68(6): p. 682-90.

OP-SH01 Sports History

FROM COLD TO CORDIAL. THE CHANGE OF RELATIONS BETWEEN THE UNESCO AND THE IOC IN THE LATE 1970S

REITER, M.

University of Vienna

Introduction The General Conference of the United Nations Educational, Scientific and Cultural Organization (UNESCO) in 1976 marked a far reaching turning point for the international political sport system. UNESCO's members officially decided to enshrine Sport in their agenda - a subject that had been previously dominated by the International Olympic Committee (IOC). In order to create the International Charter of Physical Education and Sport, an intergovernmental committee was established with the aim of presenting the new, ground breaking Charter at the next General Conference in 1978 (UNESCO, 1977). It goes without saying that this development was seen as an invasion in the field of IOC's activity and therefore evoked major criticism from the 'competing' organization. (Landry et. al. 1996). Interestingly, international politics and media joined the discussions. This study shows why UNESCO's Sport Charter was not only an inter-organizational hot-button issue, but also caused international concerns amidst the lingering Cold War between East and West. Methods and Sources The methodological approach to this study is shaped by the primary sources used. Fundamental research has been carried out mainly in the Historical Archives of the Olympic Studies Centre in Lausanne. The analyzed material involves both official IOC and UNESCO documents as well as contemporary news coverage by international papers. Furthermore, the correspondence between the President of the IOC and the UNESCO General Secretary has been included in the analysis. Results In 1976 UNESCO's decisions were seen by many as a threat to the IOC's leading role in the international sport system as well as another potential conflict issue between East and West. Yet the fear of some (western) IOC members that UNESCO could become a stakeholder for the countries of the East with regard to sport politics turned out to be unfounded. In the context of the growing conflict between East and West in the late 1970s and early 1980s, the IOC and UNESCO were anxious to cooperate instead of competing in the field of international sport politics. Discussion The sudden change of relations from cold to cordial leaves space for discussion and speculation. Could a confrontation between UNESCO and IOC have led to a definitive sport political separation of East and West and would the UNESCO have been able to implement a more democratic approach to international sport politics? RIDING INSTRUCTORS, GENDER, MILITARISM, AND STABLE CULTURE IN SWEDEN: CONTINUITY AND CHANGE IN THE TWENTIETH CENTURY

THORELL, G., HEDENBORG, S.

The Swedish national Equestrian centre, Gothenburg university, Malmö university

Introduction Swedish equestrian sport underwent significant changes during the twentieth century from being connected to men and the army to being associated with women and leisure activities. Previous research has shown that a stable culture with masculine military norms still exists in spite of these changes. The purpose of this study is to explore why these norms continue to influence Swedish equestrian sport. Riding instructors and their education at the Swedish National Equestrian Centre (SNEC) are focused in order to understand and explain the norms of stable culture. Method Institutional economic theory and gender theory are used to explain continuity and change in stable culture. The source material consists of written documents, books and interviews with four riding instructors. Results Between the 1960s and the 1980s, SNEC was transformed from the army's equestrian academy to the educational centre for the equestrian federation with civilian students at the riding instructor courses. An increasing number of women began participated in the courses. Course syllabi show that the instructor courses were very similar before and after the equestrian organization took over SNEC. The riding instructors explain that riding skills and practical skills were important, during their educational time at SNEC, as well as efficiency, orderliness, and responsibility. The leadership was characterized to be authoritarian and provided a sense of security. Discussion Military norms have been reproduced in the education of the riding instructors. When the equestrian federation took over SNEC they could have replaced the teachers and demanded a different educational culture, but did not. The result explain why the institutional arrangements of stable culture were difficult to change; such changes would simply have cost too much. The federation would also have needed time to readjust, find new teachers, and exchange one educational system for another. The female informants did not feel that they were treated differently on account of their gender, instead, they underline that they appreciated the military values, and the emphasis on discipline. The military norms creating overlapping gender constructions that diverged from what was regarded as feminine and masculine in society at large. References Dashper, K. (2012). OXFORD AND CAMBRIDGE BOAT RACE: PERFORMANCES AND PHYSICAL CHARACTERISTICS OF CREWS BETWEEN 1890 AND 2014

EDWARDS, A.M., GUY, J.H., HETTINGA, F.J.

St Mark and St John University; University of Essex

Introduction: The Oxford and Cambridge Boat Race is one of the oldest, continuing sporting events in the world. Historically as well as scientifically, the race is of unique value, as performance data have been collected in the same event, on the same course over 2 centuries: the ideal set-up for a field-based longitudinal evaluation (Desgorges et al. 2008). The purpose of this study was to examine the historical development of Boat Race performances and physical characteristics of Oxford and Cambridge crews for races between 1890 and 2014. Methods: Linear regression analysis was used to investigate the development of performance and average body size of the crews from both universities. Changes to performances and crew characteristics were further assessed in 10-year clusters for decade by decade comparisons. Results: Significant negative correlations were observed between performance and time (1890-2014) for both

Oxford ($r = -0.67$; $P < 0.01$) and Cambridge ($r = -0.64$; $P < 0.01$). As an overall effect, crew performance times have improved markedly (~2min 20s faster than the 1890s) with the first significant gains from baseline (1890s) achieved in the 1950s (Cambridge) and the 1960s (Oxford) decades which coincided with significant increases in the average body mass of the competing crews ($P < 0.01$). In 1890, the average body mass of the crews from both universities was 77.2kg, while crews are now significantly heavier than that (~88-95 kg). Conclusion: Analysis of the historical developments in the Boat Race provides a unique opportunity to better understand factors relevant for optimal performance (Hofmijster et al. 2007). Performance in the Boat Race has evolved substantially since 1890 and this has been accompanied by changes to the physicality of the competitors, the equipment they use and the training strategies they employ. IS-PM04 Active Pregnancy

GUIDELINES FOR PREGNANCY AND POSTPARTUM PELVIC FLOOR MUSCLE TRAINING AND PREVALENCE OF URINARY INCONTINENCE

BØ, K.

Norwegian School of Sport Sciences

INTRODUCTION: Pelvic floor dysfunction (PFD) has been defined as presence of symptoms of urinary (UI) or anal (AI) incontinence, pelvic organ prolapse (POP), sensory or emptying abnormalities of the lower urinary tract, defecation dysfunction, sexual dysfunction and chronic pain syndromes (1). Several studies have found a high prevalence (28-80%) of UI in nulliparous women and in female elite athletes with the highest prevalence in sports involving high impact activities such as trampoline jumping and gymnastics (2). Postpartum prevalence of any type of UI in primiparous women during the first year postpartum, regardless of delivery mode, range between 15% and 30% (1). The aim of this presentation is to give an overview of the effect of pelvic floor muscle training in prevention and treatment of UI during pregnancy and in the postpartum period **RESULTS:** A Cochrane review concluded that 'pregnant women without prior urinary incontinence (prevention) who were randomized to intensive antenatal pelvic floor muscle training (PFMT) were less likely than women randomized to no PFMT or usual antenatal care, to report UI up to six months after delivery (about 30% less; risk ratio (RR) 0.71, 95% CI 0.54 to 0.95, combined result of 5 trials)' (2). Postpartum the Cochrane review concluded that 'postnatal women with persistent urinary incontinence (treatment) three months after delivery and who received PFMT were about 40% less likely than women who did not receive treatment or received usual postnatal care to report urinary incontinence 12 months after delivery (RR 0.60, 95% CI 0.35 to 1.03, combined result of 3 trials)'. It seemed that the more intensive the program the greater the treatment effect. However, the Cochrane review also concluded that 'the extent to which mixed prevention and treatment approaches to PFMT in the postnatal period are effective is less clear. **DISCUSSION:** There is a need for RCTs on the effect of PFMT in elite athletes during pregnancy and in the postpartum period. Given the evidence for PFMT on UI in the general female population during pregnancy and in the postpartum period, elite athletes should be offered supervised PFMT after childbirth. **REFERENCES:** 1. GUIDELINES AND BENEFITS OF SUPERVISED PROGRAMS OF MODERATE-INTENSITY EXERCISE PERFORMED THROUGHOUT PREGNANCY

PERALES SANTAELLA, M., BARAKAT CARBALLO, R.

Camilo Jose Cela University

Guidelines and benefits of supervised programs of moderate-intensity exercise performed throughout pregnancy Maria Perales¹; Ruben Barakat² 1 Camilo Jose Cela University-Faculty of Health 2 AFIPE Research Group-Technical University of Madrid The evidence on the benefits of an healthy lifestyle including exercise, in pregnant women's and new-born health and pregnancy outcomes is increasing. However, somehow, there are still social barriers to deliver proper programs and increase adherence of pregnant women and professionals. This presentation will focus the influence of supervised programs of combine moderate-intensity exercise (aerobic and resistance), performed throughout pregnancy on maternal and foetal pregnancy outcomes, such as: the improvement of the maternal perception of health status; how it helps to control excessive weight gain; the risk of preterm delivery for healthy pregnant women; the reduction in the rate of caesarean and instrumental deliveries, its effects on the prevention of antenatal depression, and the maternal cardiac adaptations to this program. Furthermore, it will focus on the current guidelines for exercise performed over the first, second, and third trimesters of pregnancy including aerobic moderate-intensity exercise, light-intensity resistance training and pelvic floor training. These guidelines are essential for designing not only safety but also effective exercise programs to avoid maternal and fetal complications during pregnancy associated with sedentarism

BIOMECHANICAL LOADING OF GAIT DURING PREGNANCY

SANTOS-ROCHA, R.1,3, BRANCO, M.1,3, AGUIAR, L.2,3, VIEIRA, F.2,3, VELOSO, A.P.2,3

1: ESDRM-IPSantarém (Rio Maior, Portugal), 2: FMH-ULisboa (Lisboa, Portugal), 3: CIPER (Lisboa, Portugal)

Introduction Pregnancy is a special phase of women's lives, which process leads to several changes in hormonal, anatomical, body composition, and musculoskeletal systems of women. The changes occurring in the body between the second and the third trimesters of pregnancy, lead to an increase in the mechanical load of the lower limb during gait and other motor tasks [1]. The purposes were to analyse the biomechanics (kinematics and kinetics) of gait throughout pregnancy and postpartum [2,3]. Methods Eleven pregnant women participated in the study. Anthropometric and biomechanical data were collected at the Laboratory of Biomechanics and Functional Morphology during the later stages of each trimester of pregnancy and once in the postpartum period. A marker set-up [4] was used for limb segments and CODA protocols for models of the pelvis segment. Kinematic and kinetic data were collected by means of 12 infrared high-speed cameras (Qualisys, Sweden), two Kistler and one AMTI force platforms, at a rate of 1000 Hz. We have described the temporal and spatial parameters of the gait cycle, the angular kinematics [2] of the lower limb, and the moments of force [3] at the ankle, knee and hip joints, in the three trimesters of pregnancy and in the postpartum period. Results Women maintain the same temporal and spatial parameters of gait throughout pregnancy and during the postpartum period. The angular kinematics of lower limb shows few adaptations in pelvis and hip joints. The hip is the joint that shows the greatest changes in joint kinetics during pregnancy, with an increase of the internal loading associated with the hip moments in the transverse plane. In the other planes of motion, joint moments and power shows a significant decrease to the end of pregnancy or an increase from some stages of pregnancy to the postpartum period. Discussion The biomechanical adaptations are related to body stability and fall prevention, however, they might be also related to low back pain. Hip and ankle joints seem to have the major changes and, therefore, the ones with an overload on the lower limb. Based on the data available, some recommendations for exercise prescription can be developed in order to improve the well-being of women throughout pregnancy. IS-SP02 Sports Nutrition Symposium - Prime, Perform and Recover: exploring nutrition strategies surrounding exercise sponsored by GSSI

ATHLETE PREPARATION: BEYOND THE BASICS

HAWLEY, J.

Mary MacKillop Institute for Health Research

Advances in molecular biology during the past 20 years have allowed scientists to elucidate how endurance- and resistance-based exercise stimulate skeletal muscle remodelling (i.e., promote mitochondrial biogenesis and muscle hypertrophy). A growing field of interest directly arising from our understanding of the molecular bases of training adaptation is how nutrient availability alters the regulation of many contraction-induced events in muscle in response to exercise. Changes in energy availability (acute and chronic) and macronutrient composition alter the concentration of blood-borne substrates and hormones, causing marked perturbations in the storage profile of skeletal muscle and other insulin-sensitive tissues. In turn, muscle energy status exerts profound effects on resting fuel metabolism and patterns of fuel utilization during exercise, as well as acute regulatory processes underlying gene expression and cell signalling. As such, nutrient-exercise interactions have the potential to activate or inhibit many biochemical pathways with putative roles in training adaptation. This talk will focus on recent trends in athlete preparation that have employed dietary periodisation protocols to enhance training adaptation and improve performance in endurance sports.

FRUCTOSE METABOLISM IN A FUNCTIONAL PERSPECTIVE. IMPLICATIONS FOR ATHLETES

TAPPY, L.

University of lausanne

Substantial amounts of fructose are present in our diet. Either as free fructose in fruits, or as part of sucrose or high fructose corn syrup in drinks. Unlike glucose, fructose cannot be metabolized by most cells, and has first to be converted into lactate, glucose or fatty acids by enterocytes, hepatocytes and kidney proximal tubule cells, which all express specific fructose-metabolizing, gluconeogenic, and lipogenic enzymes. The specific metabolism of fructose may possibly exert reported detrimental effects in sedentary subjects due to production of hepatic lipids, increased intrahepatic fat accumulation and stimulation of VLDL secretion. During exercise, however, its particular metabolism may present some advantages for athletes. First, fructose and glucose are absorbed through distinct gut transporters, co-ingestion of glucose and fructose could increase total carbohydrate absorption and oxidation. Second, fructose is largely metabolized into glucose and lactate, resulting in a net local lactate release from splanchnic organs (mostly the liver). This hepatic to muscle lactate shuttle may be advantageous by providing lactate as an additional energy substrate to the working muscle. Following exercise, co-ingestion of glucose and fructose mutually enhance their own absorption and storage, and may thus contribute to whole body glycogen resynthesis.

NUTRITION STRATEGIES TO MAXIMISE RECOVERY AND ACCELERATE RETURN TO PLAY

PHILLIPS, S.

McMaster University

Injury in sport is often accompanied by disuse atrophy, which must be countered before a return to play. Inflammation, if present, also needs to be treated to provide an environment for a full return to play. Disuse atrophy is primarily due to a decline in muscle protein synthesis with a small contribution of increased proteolysis. In this presentation the evidence for nutritional mediation of disuse atrophy will be discussed in the context of several nutritional mediators including: protein, leucine, creatine, and n-3 polyunsaturated fatty acids. A brief word on recovery of connective tissue will also be made. All data will be taken from human studies and recommendations will be made for the practitioner for nutritional strategies to promote recovery and return to play as soon as possible after injury.

Invited symposia**IS-PM05 Impact of exercise on vascular disease: benefits and mechanisms****PHYSIOLOGICAL MECHANISMS OF EXERCISE ON VASCULAR FUNCTION**

ADAMS, V.

Heart Center Leipzig

Over the last decade it became evident that physical exercise training programs for patients with cardiovascular disease exerts beneficial effects with respect to exercise capacity, thereby influencing cardiovascular mortality. Based on animal models as well as on several clinical studies, targets of the training intervention could be identified. Organs influenced by exercise training are beside the myocardium, the endothelium, the respiratory system including the diaphragmatic muscle and the peripheral skeletal muscle. In the vascular system nitric oxide (NO) is one of the main factor responsible for the regulation of the vascular function. The concentration of bioavailable NO is significantly reduced in patients with cardiovascular disease and exercise training has the potency to prevent this reduction. During the talk several mechanisms will be discussed which may be responsible for the beneficial effect of exercise training on the NO system. These effects include modulation of eNOS expression and activation by phosphorylation and modulation of NO by reactive oxygen species (ROS). Beside these direct effects on the eNOS/NO system exercise training also modifies the repair capacity of the endothelial cell layer. In this context the regulation of endothelial repair mechanisms, including endothelial progenitor cells and their modulation by adiponectin, will be discussed.

MEASURING SUBCLINICAL ATHEROSCLEROSIS IN OBESE CHILDREN

HANSSEN, H.

University of Basel

The prevalence of childhood obesity is high and its association with future cardiovascular disease in adulthood is well established. Childhood obesity has been associated with increased adult risk of coronary heart disease and premature death. In children, the associations of overweight and obesity with higher blood pressure and cholesterol have been found to be comparable to those of adults. Therefore, the early detection of subclinical markers of atherosclerosis in childhood is a challenging task of high clinical relevance. Non-invasive vascular biomarkers enable the population-wide screening of cardiovascular risk. The evidence for obesity-associated early impairments of the vasculature in children is substantial. The assessment of large artery structure and function, for example by measurements of intima media thickness and arterial stiffness, has been shown to be a feasible and reproducible screening tool in children. Our research group and others have recently shown that retinal vessel analysis is a promising new diagnostic tool for the assessment of obesity-related subclinical atherosclerosis of the microvasculature in school children. The retinal microcirculation is affected early in the process of atherosclerosis and it offers a unique opportunity to analyse the effects of obesity on small brain vessels. Macro- and microvascular biomarkers represent the cumulative cardiovascular risk on target organ damage and are necessary diagnostic means to monitor and evaluate the effects of lifestyle intervention therapies in children. The proposed presentation will focus on methodological approaches and the clinical relevance of the above mentioned vascular biomarkers in children. Moreover, it will focus on the effects of physical activity behaviour and exercise on vascular structure and function in childhood.

WALKING TRAINING IN PERIPHERAL VASCULAR DISEASE: CARDIOVASCULAR RISK, FUNCTION AND REGULATION

FORJAZ, C.

University of Sao Paulo

Patients with peripheral arterial disease commonly experience intermittent claudication during walking, which impairs walking capacity, and consequently, decreases quality of life. In addition, they also present impaired cardiovascular function and regulation, which increase cardiovascular morbidity/mortality. Walking training is recommended as the first line of treatment for these patients because it has proved to increase walking capacity. However, in order to decrease mortality in this population, walking training should also produce cardiovascular benefits. Acute and chronic cardiovascular adaptations have been reported after walking in other populations, such as hypertensives, diabetic and cardiac patients. In the last years, our research group has studied systemic and local hemodynamic responses as well as cardiovascular autonomic modulation adaptations to walking in patients with intermittent claudication, and interesting results and limitations for walking benefits have been observed. The invited presentation will focus, initially, on the acute post-effects of walking exercise on cardiovascular function and regulation in patients with intermittent claudication, comparing responses after maximal and submaximal efforts. Next, walking training effects will be discussed, focusing on walking protocol, benefits and mechanisms of improvement. Contact: cforjaz@usp.br

OP-PM09 Supplements: Protein, Creatine, Caffeine

CREATINE LOADING DOES NOT ATTENUATE MUSCLE DISUSE ATROPHY

BACKX, E.M.P.1,2,3, HANGELBROEK, R.W.1,2, SNIJDERS, T.2,3, VERDIJK, L.B.2,3, DE GROOT, L.C.P.G.M.1,2, VAN LOON, L.J.C.2,3

Introduction Short term leg immobilization leads to rapid loss of muscle mass and strength. Creatine supplementation has been shown to increase lean body mass in active individuals and augment gains in muscle mass and strength during resistance type exercise training. **Objective** To investigate whether creatine loading can attenuate the loss of muscle mass and strength during short-term leg immobilization in healthy, young men. **Methods** Thirty healthy, young men (aged 23±1 y; BMI 23.3±0.5 kg·m⁻²) were randomly assigned to either a creatine (CR) or a placebo group (PLA). Subjects received placebo or creatine supplements (20 g/d) for 5 days before one leg was immobilized by means of a full-leg cast for 7 days. Muscle biopsies were taken before creatine loading, prior to and immediately after leg immobilization and after 7 days of subsequent recovery. Quadriceps cross-sectional area (CT scan) and leg muscle strength (IRM leg extension) were assessed before and after immobilization and after the recovery week. Data were analyzed using repeated measures ANOVA. Results Five days of creatine loading tended to increase muscle total creatine content from 86±9 to 102±7 mmol per kg dry muscle (mmol·kg⁻¹) in the CR group ($P=0.06$), while muscle creatine concentration did not change in the PLA group (88±4 to 90±3 mmol·kg⁻¹; $P>0.05$). A decrease in quadriceps muscle mass was observed in the immobilized leg in both the CR and PLA groups (-465±59; $P<0.05$ and -425±69 mm²; $P<0.05$ respectively), with no differences between groups ($P>0.05$). Leg muscle strength decreased in both the CR (from 56±4 to 53±4 kg; $P<0.05$) and PLA group (59±3 to 53±3 kg; $P<0.05$), with no differences between groups ($P>0.05$). When non-responders to creatine loading were excluded (n=6), responders (n=8; 70 to 106 mmol·kg⁻¹) showed similar findings with no preservation of muscle mass or strength during immobilization when compared to the PLA group. **Conclusion** Creatine supplementation does not attenuate the loss of muscle mass and strength during a short period of leg immobilization. CAFFEINE AND ITS INFLUENCE ON PERFORMANCE, HEART RATE VARIABILITY, BLOOD PRESSURE AND TIDAL VOLUME IN PARA- AND TETRAPLEGIC INDIVIDUALS COMPARED TO ABLE-BODIED CONTROLS

FLUECK, J., SCHAFELBERGER, F., LIENERT, F., PERRET, C.

Swiss Paraplegic Centre

Introduction: Caffeine (CAF) ingestion leads to ergogenic effects in high-intensity and endurance exercise in able-bodied (AB) athletes. To date, it is unclear whether such an effect could be detected in wheelchair athletes as well due to impaired sympathetic nervous system activation of spinal cord injured individuals. The study investigated the effects of CAF on upper body performance in para- (P) and tetraplegic (T) compared to AB participants. Additionally, heart rate variability (HRV), blood pressure (BP) and tidal volume (VT) were assessed to gain more information about sympathetic activation. **Methods:** 17 AB (median [minimum; maximum]; VO₂peak 39.9ml/min/kg [23.6; 57.6]), 10 P (VO₂peak 34.4ml/min/kg [19.5; 48.8]) and 7 T participants (VO₂peak 13.6ml/min/kg [8.6; 16.3]) participated in this double-blind, placebo-controlled and randomized study. Participants performed twice a 3min all-out arm crank test 1h after the ingestion of either 6mg/kg CAF or placebo (PLC). Plasma CAF, epinephrine (EPI) and norepinephrine (NOR) concentrations were analyzed pre- and post-ingestion. Pre- and 40min post-ingestion, HRV, VT during HRV measurement and BP were assessed. **Results:** There was no significant increase in peak and mean power over 3min after the ingestion of CAF in the three groups. The median for peak power showed an increase of 46W (AB), 21W (P) and 2W (T) after CAF compared to PLC. Performance in the first 30s to 60s of the test after CAF ingestion significantly increased in P ($p=0.028$) but not in AB ($p=0.44$) and T ($p=0.61$). Plasma CAF concentration significantly increased in all three groups (AB: $p=0.005$; P: $p=0.008$; T: $p=0.018$) post CAF ingestion. A significant increase from pre to post CAF ingestion in EPI was found in AB ($p=0.002$) and in P ($p=0.032$) but not in T ($p=0.63$). Most HRV parameters did not change post CAF ingestion compared to PLC, whereas LF/HF ratio was significantly reduced in P ($p=0.028$). VT significantly increased post CAF ingestion in AB ($p=0.021$) and P ($p=0.036$) but not in T ($p=0.34$). Systolic and diastolic BP increased significantly post CAF ingestion in AB (SBP: $p=0.003$; DBP: $p=0.021$) and T (SBP: $p=0.043$; DBP: $p=0.042$) but not in P (SBP: $p=0.09$; DBP: $p=0.33$). **Discussion:** CAF seemed to enhance performance between 30 and 60s in P but not in AB and T. However, a clinically relevant increase in peak power occurred in AB and P. VT increased from pre to post CAF ingestion in AB and P possibly due to an increase in plasma EPI. Furthermore, CAF ingestion seems to elevate BP in all three groups. Contact: joelle.flueck@paraplegie.ch

RESISTANCE TRAINING REDUCES T HELPER CYTOKINE LEVELS BUT NOT CARDIOMETABOLIC RISK FACTORS IN HIV-INFECTED INDIVIDUALS RECEIVING ANTIRETROVIRAL THERAPY.

SOOKAN, T.1, ORMSBEE, M.J.1,2, ANTONIO, J.3, MAGULA, N.P.1, MOTALA, A.A.1, LALOO, U.G.1, LIEBENBERG, L.1, MCKUNE, A.J.1,4

1. University of KwaZulu Natal, 2. Florida State University, 3. Nova South-eastern University, 4. Canberra University

Introduction A shift from T helper (Th1) to Th2 cytokine profile is associated with disease progression in HIV-infected individuals and has been linked to lipodystrophy (Drellichowska et al., 2015). Resistance training (RT) in combination with protein-containing nutrition has shown to improve strength and body composition. Therefore the aim of this study was to determine the effect of combined resistance training and whey protein on body composition, Th1 and Th2 cytokines and cardiometabolic risk in HIV infected individuals receiving ART. **Methods** Forty HIV-infected participants (40.8 ±7.7 yrs, 70.8 ±16 kg, BMI 30.9 ±7.2 kg/m²) receiving ART (≥18 months) were randomly assigned to either a whey protein/progressive resistance training (PRT) group (n=18), placebo/PRT group (n=14) or control group (n=8). Participants received either 20g whey or placebo (maltodextrin) pre and immediately post each PRT session. Whole body RT was performed 2/week for 3 months with the loads progressing from 40-85% of one repetition maximum (IRM). Measurements including height, weight, waist and hip, body composition (DEXA) and 1RM testing were performed 48-72 hrs before (pre = T1) and after 3 months (T2) PRT

program and 3 months (T3) following the cessation of the PRT programme. Additionally, venepuncture was done to look at systemic immune, inflammatory and cardiometabolic risk markers. Statistical analysis included two-way ANOVA with multiple comparisons (2 groups x 3 time points) in the PRT groups and one-way ANOVA with repeated measures in the control group. Alpha was set at $p \leq 0.05$. Results There was a significant ($p < 0.001$) main effect of time for the PRT groups and control group for the HOMA-IR index. Post-hoc testing demonstrated that the HOMA-IR index significantly increased from T1 to T2 ($p = 0.002$) and from T1 to T3 ($p < 0.001$) for the placebo/PRT and whey/PRT groups, respectively. The control group increased significantly ($p < 0.001$) from a T1 value of 0.37 to 1.44 at T2 and ($p = 0.002$) a T1 value of 0.37 to 1.23 at T3. There was a significant ($p = 0.05$) main effect of time for the PRT groups for the Th2 cytokine IL-10, post hoc testing showed no significant time effect over the 3 time points. There was a significant main group effect for CD8% ($p = 0.05$), IL-10 ($p = 0.01$), IL-13 ($p = 0.05$) and IL-12 ($p = 0.02$). Post hoc testing showed a significant group effect with the placebo/PRT lower over the 3 time points for IL-10 ($p = 0.008$) and IL-12 ($p = 0.016$). Conclusion HIV serves as both a metabolic and an inflammatory challenge (Singh et al., 2016). Our study demonstrated that a PRT programme can decrease anti-inflammatory and pro-inflammatory cytokines possibly reflecting reduced systemic inflammation in HIV-infected individuals (Reuter et al., 2012). CHRONIC INGESTION OF A LOW DOSE OF CAFFEINE INDUCES TOLERANCE TO THE PERFORMANCE BENEFITS OF CAFEINE

ROSS, B.

Loughborough University

This study examined the effect of 4 weeks caffeine supplementation on endurance performance. Eighteen low habitual caffeine consumers (<75 mg/day; age: 21.2 ± 1.8 y; body mass: 74.05 ± 8.6 kg; VO₂peak: 51.38 ± 8.73 ml·kg⁻¹·min⁻¹) were randomly assigned to ingest caffeine (1.5 mg/kg–3 mg/kg; titrated) or placebo for 28 days. Groups were matched for measures of age, body mass and VO₂peak ($P > 0.05$). Prior to supplementation all subjects completed one VO₂peak test, one familiarisation trial and two experimental trials (acute 3 mg/kg caffeine [CAF1] and placebo [PLA]). During the supplementation period a second VO₂peak test was completed on day 21 prior to a final acute 3 mg/kg caffeine trial (CAF2) on day 29. Trials consisted of 60 min cycle exercise at 60% VO₂peak followed by a 30 min workload challenge. All subjects produced more work during the CAF1 trial compared to PLA, with increases of 38.4 ± 19.9 kJ (383.3 ± 75 kJ; 344.9 ± 80.3 kJ, $P=0.001$) and 21.4 ± 13.1 kJ (354.5 ± 55.2 kJ; 333.1 ± 56.4 kJ, $P=0.004$) for the caffeine and placebo group, respectively. This response was no longer apparent following 4 weeks of caffeine supplementation (CAF1: 383.3 ± 75 kJ; CAF2: 358 ± 89.8 kJ, $P=0.025$), but remained in the placebo group (CAF1: 354.5 ± 55.2 kJ; CAF2: 351.8 ± 49.4 kJ, $P>0.05$). No between-group differences were observed in caffeine metabolism, hormonal concentrations or substrate oxidation ($P>0.05$). It appears chronic ingestion of a low dose of caffeine can result in the development of tolerance.

CAFFEINE AND SALIVA STEROIDS IN YOUNG HEALTHY RECREATIONALLY TRAINED WOMEN: IMPACT OF REGULAR CAFFEINE INTAKE

RIETH, N.1,2, VIBAREL-REBOT, N.1,2, BUISSON, C.3, JAFFRÉ, C.4, COLLOMP, K.1,3

Collégium Sciences et techniques - Pôle STAPS - Université Orléans

Introduction Caffeine induces a lot of metabolic effects, but its impact on steroid hormone concentrations as well as on their diurnal pattern remained poorly known. The purpose of this investigation was therefore to determine the effects of acute caffeine intake on saliva cortisol and DHEA concentrations during a waking diurnal cycle in regular caffeine users (CU) and non caffeine users (NCU). Methods Nineteen healthy young recreationally trained females (physical activity for 4–6 h/week, 19.5 ± 0.3 years, 57.1 ± 1.6 kg) were recruited to participate in the study. Saliva samples were collected from at awakening, and then every 3 hours from 0900 to 2100 hours a day without any caffeine intake and a day with caffeine intake, i.e., 150 mg twice a day, respectively at 0730 and 1330. Results Diurnal decline for cortisol and DHEA was observed during the experimental days with and without caffeine for both NCU and CU subjects, without any significant alteration in their diurnal pattern by caffeine. However, morning but not afternoon caffeine intake induced a significant increase at 0900 in cortisol for all subjects ($p<0.01$) and in DHEA only in CU group ($p<0.05$). Discussion Acute caffeine intake, whatever the regular caffeine use, does not affect the circadian pattern of saliva metabolic steroids in healthy recreationally-trained women. To our knowledge, only few studies investigated short-term caffeine intake on DHEA response (Wedick et al., 2012, MacKenzie et al., 2007) but the acute effects of caffeine administration on DHEA have never been studied. Further studies are necessary to determine whether the marked transient increase in morning cortisol induced by caffeine, combined or not with DHEA increase, may have a clinical impact. ELECTROPHYSIOLOGICAL CHANGES IN THE BRAIN INDUCED BY CAFFEINE OR GLUCOSE NASAL SPRAY

DE PAUW, K.1, ROELANDS, B.1, VAN CUTSEM, J.1, MARUŠIČ, U.2, TORBEYNS, T.1, MEEUSEN, R.1

1: VUB (Brussels, Belgium), 2: UP (Koper, Slovenia)

Introduction Since a direct link between the mouth cavity and the brain has been demonstrated for glucose (GLUC) and caffeine (CAF) (De Pauw et al, 2015), the question arises whether the nasal cavity also provides a direct link to the brain. Therefore, the aim of this study is to examine the influence of nasal sprays (NAS) containing GLUC, CAF or placebo (PLAC) on brain activity using the cognitive Stroop task and electro-encephalography (EEG). Methods Ten healthy male subjects (Age: 22 ± 1 yrs) performed 3 experimental trials, separated by at least 2 days. Each trial included a 20s NAS period in which solutions PLAC, GLUC or CAF were provided in a double-blind, randomized order. The final [CAF] and [GLUC] was 15 and 80mg/ml, respectively. During each trial 4 cognitive Stroop tasks were performed; two familiarization trials, one pre and one post NAS trial. Reaction times and accuracy for different stimuli (neutral: NEUTR, congruent: CON, incongruent: INCON) were determined. EEG was continuously measured throughout the trials using 32 active electrodes at a sampling rate of 256Hz. Datasets were filtered, re-referenced to an average of all electrodes and cleaned before further processing. During the Stroop tasks pre and post NAS the latency (ms) and amplitude (μ V) of the visually-evoked event-related potential component P300 was assessed. During NAS source localization using standardized low resolution brain electromagnetic tomography (sLORETA) was applied. This program provides information of altered electrocortical activity of brain areas within certain frequency ranges. Parametric tests were performed using SPSS version 22.0. Standardized LORETA applies statistical analyses at voxel level based on the Fisher's permutation test (Fisher,

1935) and a bootstrap method with 5000 randomizations. Results and discussion All NAS solutions activated the olfactory bulb and, consequently, the anterior cingulate cortex. Only CAF-NAS also increased (theta and beta) activity in frontal cortices, possibly due to the activation of nasal bitter taste receptors. Furthermore, GLUC-NAS increased the beta activity within the anterior insular cortex, but not in frontal brain areas. A reduced latency and increased amplitude of P300 are associated with enhanced information processing. P300 analysis showed that CAF-NAS reduced the P300 latency at Fp1 for NEUTR ($p=0.005$). GLUC-NAS reduced the P300 latency at C3 for CON ($p=0.024$). Furthermore, the P300 amplitude at F4 increased for CON ($p=0.02$) and INCON ($p=0.029$), and reduced for NEUTR ($p=0.010$). Brain activity is clearly altered, but no effect on cognitive performance was demonstrated. References De Pauw K, Roelands B, Knaepen K, Polfliet M, Stiens J, Meeusen R. (2015). *J Appl Physiol*, 118(6), 776-82. Fisher RA. New York: Hafner, 1935.

IS-BN03 HAMSTRING MUSCLE FUNCTION IN HUMAN MOVEMENT: IMPLICATIONS FOR HAMSTRING STRAIN INJURY DETECTION AND PREVENTION

HAMSTRING STRAINS IN TYPICAL TRAINING TASKS AND IN ISOKINETIC ECCENTRIC CONTRACTIONS OF DIFFERENT VELOCITIES

MCGUIGAN, M.P., JAMES, D., MACDONALD, B.

University of Bath

Acute hamstring injuries remain the most prevalent muscle injuries in sport. Muscle strain injuries occur due to high active strain of the muscle (1). The circumstances which have the potential to produce this high active strain in the hamstrings in sprinting have been well documented (2). During late swing, when the hip is flexed, the hamstrings act to decelerate the shank. This results in lengthening of the muscle-tendon unit and therefore potentially reduced capacity for active force generation within the muscle fascicles. The precise timing of muscle injury is not yet clear, but it can be argued that if the lengthening of the muscle fascicles has been excessive then they are not able to generate sufficient force to resist the external force due to body weight when the foot contacts the ground, resulting in further lengthening of the muscle and damage. What has not yet been investigated *in vivo* is the way in which the active and passive elements of the hamstring muscles behave during eccentric contractions. In order to more fully understand the risk factors for hamstring injuries and the inciting event for injury it is imperative to understand the relative lengthening of the different elements of the muscle. Extensive study of the ankle plantarflexor muscles has revealed that the strain of muscle fascicles does not mimic that of the whole muscle-tendon unit: with the majority of the increase in length required for ankle dorsiflexion in running occurring in the compliant Achilles tendon, and the muscle fascicles shortening slowly (4). In this presentation I explore whether the same de-coupling of muscle fascicle and muscle-tendon unit occurs in the hamstring muscles. Due to their much longer muscle fascicles one might hypothesise that the strain of their muscle-tendon units is more driven by the length change of the fascicles than the tendon, but conversely the force generating capacity of the active component of the muscle should be sufficient to resist the force due to the inertia of the shank in late swing, and allow the required muscle-tendon unit lengthening to occur in the passive elements. We have used a combination of ultrasound, motion analysis and EMG to determine biceps femoris fascicle length and muscle-tendon unit length during isokinetic eccentric contractions at different velocities and some typical training tasks in order to explore the muscle's behaviour during controlled eccentric tasks. HAMSTRING STRAINS IN HIGH SPEED MOVEMENTS- IMPLICATIONS FOR INJURY PREVENTION

CRONIN, N.

University of Jyväskylä

Hamstring strain injuries (HSIs) are very common in sport, and the biceps femoris (BF) is the most frequently injured muscle. Activities involving large and/or fast hamstring strains present the greatest injury risk, e.g. soccer and sprinting. Importantly, the mechanism of HSI is poorly understood because hamstring length changes have not been directly studied in movements such as running, where injuries often occur. Thus, it is important to establish whether hamstring muscle fibres actually undergo lengthening during fast movements, and to assess whether these length changes are a possible source of HSIs. In theory, hamstring length changes can be studied with ultrasound imaging. However, this approach has severe limitations in fast movements, and where muscle deformations are substantial and occur in three dimensions. In this talk I will introduce our attempts to quantify BF strains in different tasks, and highlight the limitations of this method. I will also present multi-channel electromyography data showing how muscle activity varies along the length of hamstring muscles in different tasks. Finally, the relevance of these findings for injury mechanics and prevention will be discussed.

IMPACT OF NORDIC HAMSTRING VERSUS HIP EXTENSION EXERCISE ON BICEPS FEMORIS FASCICLE LENGTHS AND ECCENTRIC KNEE FLEXOR STRENGTH

SHIELD, A., BOURNE, M., WILLIAMS, M., TIMMINS, R., OPAR, D.

Queensland University of Technology

Introduction Recently we have shown that fascicle lengths in the biceps femoris long head (BFLH) and eccentric knee flexor strength are risk factors for hamstring strains in elite Australian soccer players (Timmins et al., 2015) so it was of interest to compare the effects of two common hamstring exercises on these variables. Methods We compared the effects of 10 weeks of Nordic hamstring (NH) to hip extension (HE) training on biceps femoris long head fascicle length, determined via B-mode ultrasound, and eccentric knee flexor strength, determined during the performance of the Nordic hamstring curl. We also assessed the effects of training on hamstring muscle volumes as determined via magnetic resonance imaging. Results Biceps femoris long head fascicle lengths increased from 10.66 ± 0.79 to 12.00 ± 0.70 cm ($p<0.05$) after HE training and from 10.55 ± 0.87 to 12.76 ± 1.15 cm ($p<0.05$) after NH training. No changes were observed in fascicle lengths in an untrained control (CON) group. Peak forces during the Nordic hamstring exercise increased significantly in both exercise groups (from 320.1 ± 83.9 to 430.6 ± 91.4 N and from 362.4 ± 40.2 to 459.7 ± 42.2 N in the HE and NH curl groups, respectively)

but were unchanged in the CON group (from 346.6 ± 57.9 at baseline to 336.3 ± 73.0 after 10 weeks). BFLH volume increased significantly more after HE than NHE (mean difference = 6.72% , 95% CI = 0.32 to 13.11%, $p = 0.037$) and CON groups (mean difference = 12.10% , 95% CI = 5.71 to 18.50%, <0.001). NH training resulted in hypertrophy to the semitendinosus and bicep femoris short head whereas the HE resulted in more homogenous growth of all muscles. Discussion Given the recent findings that BFLH fascicle length and Nordic strength are risk factors for hamstring injury in elite Australian soccer players (Timmings et al., 2015) the current findings suggest that the hip extension exercise is likely to have injury preventative effects and may have particular value in restoring biceps femoris long head muscle size after injury. However, the greater muscle excursions in the hip extension did not result in greater fascicle length changes than the Nordic exercise, which provided a powerful stimulus for fascicle lengthening. References Timmings et al., (2015) Short biceps femoris fascicles and eccentric knee flexor weakness increase the risk of hamstring injury in elite football (soccer): a prospective cohort study. IS-BN04 FATIGUE AND FATIGABILITY IN HEALTH AND DISEASE

THE ADJUSTMENTS THAT LIMIT FATIGABILITY IN HEALTHY YOUNG ADULTS

DUCHATEAU, J.

Université Libre de Bruxelles

Fatigue is a disabling phenomenon that emerges due to demands placed on both the nervous system and muscle fibres during sustained activity. Our understanding of the interactions between these two systems remains incomplete (Enoka & Duchateau, 2016). Although the central nervous system continuously adjusts the activation signal sent to the involved muscles during a prescribed task, the adjustments that occur during prolonged or repetitive motor actions disrupt this interaction and lead to task failure. In addition to changes in the motor system, some of the neural adjustments observed during fatiguing contractions involve modulation of afferent feedback that arises from metabolic and chemical changes within the muscle (see Taylor et al., 2016). A direct approach to determine the factors that influence the time to task failure is not possible in humans. Rather, the typical strategy is to compare that outcomes achieved with different experimental approaches. For example, one can compare the neural adjustments of two tasks that differ only by the type of control (Hunter et al., 2002). Another strategy is to manipulate factors located at cortical level by using magnetic or electrical stimulation (Abdelmoula et al., 2016) or by the administration of drugs that modify the concentration of some brain neurotransmitters (Klass et al., 2016). Changes in afferent feedback from the muscle can also be induced by mechanical (vibration) or electrical stimulation. As cortical and spinal factors are modulated during sustained activity, several concurrent approaches probing these two neural sites and the involved muscle groups have been used to provide insight on fatigue and fatigability. Collectively, the results of these studies indicate that although both cortical and spinal factors contribute to the decrease in performance, the relative influence of the two sets of factors on endurance time are task dependent. Nonetheless, changes at spinal level appear to play a key role in establishing the level of fatigability and likely explain why it becomes progressively more difficult to activate spinal motor neurones during long-lasting submaximal efforts. The purpose of this keynote presentation is to review current knowledge on the interaction between the nervous system and muscle during fatiguing contractions and to discuss the potential mechanisms that constrain time to task failure in healthy young adults. FATIGABILITY DIFFERS WITH AGING AND TASK DEMANDS

HUNTER, S.K.

Marquette University

Age-related changes within the neuromuscular system impact physiological adjustments during a fatiguing task in old adults. Consequently, there are age differences in fatigability of various skeletal muscle groups in the upper and lower limbs. Old adults are usually less fatigable than young adults for sustained and intermittent isometric contractions at submaximal and maximal intensities (1) primarily due to muscular mechanisms (5). The age difference in fatigability however, is diminished and even reversed when the task demands vary for different muscle groups and also with the age of the older adult. Three examples highlight the task and age dependence of fatigability among various muscle groups. 1) Advanced Age: The lesser fatigability of old adults during isometric contractions is observed in persons <75 years; thereafter, older adults are more fatigable than young adults for the ankle dorsiflexor muscles and the fatigability is associated with functional performance measures (sit to stand and endurance walk) (2). 2) Cognitive Challenge: Imposition of a cognitive challenge during a sustained isometric contraction reduces the age difference in fatigability for the elbow flexor muscles especially in women (3), highlighting the involvement of cortical centers during fatiguing contractions among older adults. 3) Contraction Velocity: The age difference in fatigability varies with contraction velocity. For slow-to-moderate velocity contractions, the age difference in fatigability is lessened and even diminished due to muscular mechanisms (4). Furthermore, healthy old adults (>60 years) are usually more fatigable than young adults when performing high-velocity contractions with the knee extensor muscles, but not the elbow flexor muscles (Seneff and Hunter, unpublished data). Fatigability of fast velocity contractions with knee extensor muscles among old adults is also associated with reduced walking endurance. This presentation provides evidence that the age difference in fatigability depends on the details of the task, limb muscles, and age of the person; involves varying contributions of neural and muscular mechanisms; and has consequences for performance of functional tasks among older adults. FATIGUE CAN BE UNRELATED TO FATIGABILITY IN CLINICAL COHORTS

ENOKA, R.M., ALMUKLASS, A.M., DAVIS, L., ZIJDEWIND, I.

University of Colorado, Boulder

Introduction Despite the clinical significance of fatigue, little is known about the underlying pathophysiology and current treatments rarely produce meaningful reductions in fatigue (Kluger et al. 2013). Progress is hampered by imprecise terminology and the approaches used to quantify fatigue. Fatigue To accommodate the contemporary scope of conditions ascribed to fatigue, it is defined as a disabling symptom in which physical or cognitive function is limited by interactions between performance fatigability and perceived fatigability (Enoka & Duchateau, in press). As a symptom, fatigue can only be measured by self-report and can be quantified as either a trait characteristic or a state variable. The trait level of fatigue for individuals with multiple sclerosis (MS), for example, can be quantified with the Fatigue Severity Scale (FSS) questionnaire, whereas the state levels denotes the value "right now" and can be measured with a visual analog scale. Fatigability The functional significance of the level of fatigue reported by an individual is quantified as either the amount of work that produces it (performance fatigability) or the resting levels or rates of change in psychological factors and homeostatic variables that regulate the integrity of the performer (perceived fatigability). An elevated FSS score, for example, could be attributable to such factors as a mood disorder (e.g., depression), level of voluntary activation, or sleep disturbances. Fatigue in Multiple Sclerosis To identify those factors that contribute to the greater fatigue reported by individuals with MS, Steens et al. (2012) found that the level of fatigue in MS patients (FSS score) was associated with muscle strength (MVC force), a mood disorder (depression), performance fatigability (decline in MVC force during a sustained contraction), and the ability to sustain voluntary activation during a fatiguing contraction. Moreover, improvements in FSS score after strength training are associated with adaptations in mood and the mental component of quality of life (SF-36 questionnaire), but not strength gains (Dalgas et al. 2010). Although significant amounts of fatigue reported by individuals with MS can be explained by measuring various factors known to influence performance and perceived fatigability, much less is known about the relative roles of these factors in other neurological illnesses. Invited symposia**IS-SH03 EVIDENCE-BASED PHYSICAL ACTIVITY POLICY****EVIDENCE-BASED PHYSICAL ACTIVITY POLICYMMAKING IN HEALTH PROMOTION: WHAT IT IS AND HOW IT CAN BE DEVELOPED**

RÜTTEN, A.

Friedrich-Alexander University Erlangen-Nuremberg

Calls for basing physical activity (PA) policymaking on scientific evidence often neglect that there are three distinct types of evidence that need to be considered: evidence on (type 1) effective PA practice for health outcomes, (type 2) on effective practice of promoting PA, and (type 3) effective practice of PA policymaking. Moreover, synthesizing relevant knowledge for policymaking requires transcending the paradigm of evidence-based medicine. It should not only draw on scientific sources such as meta-analyses (scientific synthesis) but should also consider context (realist synthesis) and policymakers' experiences (pragmatic synthesis). Results of an analysis of the existing literature and of current WHO and EU PA policies indicate that all types of knowledge synthesis are currently used, albeit in a rather unsystematic fashion. Moreover, only to a limited extent does PA policymaking build on good practice criteria and develop intersector governance structures to implement policies based on these criteria. This presentation will suggest a set of criteria derived from existing scientific publications and international policy guidelines that may help further improve PA policymaking across Europe. In conclusion, evidence-based PA policymaking should build on all three types of evidence but give priority to the production of evidence to inform the policymaking process as such. It should systematically employ interactive approaches for a pragmatic synthesis of evidence to achieve its goals.

THE PHYSICAL ACTIVITY POLICY AUDIT TOOL: WHAT, WHERE AND HOW?

KAHLMEIER, S.

University of Zurich, Epidemiology, Biostatistics, and Prevention Institute EBPI

There have been recurrent calls for countries to develop a national policy approach to address physical inactivity. However, there is limited evidence on what components of national policy are effective. The Policy Audit Tool (PAT) was developed by the HEPA Europe Network to provide a standardized instrument to assess national policy approaches to PA and to facilitate the sharing of examples and experiences. PAT comprises 28 items covering policies across multiple sectors, targets and surveillance and policy implementation. It was tested in seven European countries during 2009-12 and implemented in 22 Countries in the Eastern Mediterranean Region in 2013-2014. In each country a primary contact person led data collection, ideally with support from a multi sector project team. PAT provides a structured assessment for countries to assess their current policy actions. Results indicate that PAT completion requires consultation with key stakeholders across multiple sectors. Engagement of government agencies and NGOs is desirable to collect insights from different perspectives. The findings can underpin and inform future policy development and implementation. International comparison provides useful insights and examples which can benefit both regional and global agenda. These results have informed improvements to the tool to produce PAT Version 2, which has been launched in 2015. An outline on next steps of the PAT project will be given.

HUMAN POWERED MOBILITY SUPPORTING SUSTAINABILITY: ENERGY, ENVIRONMENT, AND EDUCATION

TITZE, S.

University of Graz

Since 1995 the health-enhancing physical activity guidelines have focused on moderate-intensity physical activity in addition to vigorous-intensity physical activity. Concurrently, human powered mobility (HPM) has become acknowledged as an important domain contributing to meet the physical activity guidelines. From the public health perspective HPM expanded the reach of inactive populations substantially, because it can be incorporated into the daily life without much extra time and it is relatively safe. Furthermore, HPM alleviate congestion and lower air as well as noise pollution. In order to inform the policy makers which strategies are effective to increase HPM on a population level different study designs and methods are needed to answer the following questions: Why should HPM be promoted? How to best promote HPM with focus on the environment? How stable is HPM over time, does HPM replace other physical activity behaviors, and what is the potential role of physical education and health promotion education in relation to walking and cycling? In this presentation studies with diverse designs and measurement methods will be presented to inform about the above listed questions.

Invited symposia**IS-SH04 SPORT WITH PEOPLE CROSSING BORDERS****BECOMING AT HOME ACROSS BORDERS? SPORT AND THE POLITICS OF BELONGING**

SPAAIJ, R.

Victoria University and University of Amsterdam

This paper builds on the sociology of belonging and home to examine recreational sport as a site where people with culturally and linguistically diverse backgrounds negotiate belonging. Belonging is conceptualised as a dynamic interplay between the politics of belonging and the personal, intimate experience of becoming 'at home' in a place or in particular collectivities. Drawing on five years of fieldwork at community sports clubs and events in Australia and the Netherlands, three key questions are addressed: What kinds of belonging are constructed by people with culturally and linguistically diverse backgrounds in sport? What social processes facilitate or impede these belongings? And what forms of boundary work are involved in the negotiation of these belongings? It is shown how the kinds of belonging that people with culturally and linguistically diverse backgrounds negotiate in sport are multi-layered and situational, and how they intersect with, and are shaped by, discourses, practices and structural forces of inclusion/exclusion. In doing so, this paper will advance current understanding of the role and significance of sport in processes of migrant belonging and refugee settlement.

DANCE MOVEMENT THERAPY WITH REFUGEES

KOCH, S.C., GREY, A.

SRH University Heidelberg / Alanus University Alfter

Dance Movement Therapy (DMT) is a nonverbal psychotherapeutic treatment method aiming to improve health related outcomes. In the work with refugees, DMT can help to cross language and cultural barriers and to establish trust. For torture victims, it can reintegrate the distorted body image, from a feeling of fragmentation to a reactivation of resources and a feeling of being whole again. For all refugees, it can support cultural adaptation, integration, and bring back joy, health, and satisfaction to a scattered life path. This session introduces DMT projects with refugees at SRH University of Heidelberg (Koch) and worldwide (Grey).

SPORT AND EXERCISE THERAPY WITH PEOPLE FORCED TO CROSS BORDERS

LEY, C.

University Vienna

People who were forced to cross borders due to torture and war show a particularly high prevalence of psychosomatic and psychosocial disorders. At the same time, numerous studies have shown the somatic and psychosocial health benefits of exercise and sport. These benefits are very relevant for traumatised refugees, torture and war survivors, however they are currently scarcely used and researched. In this regard, the project "Movi Kune – moving together" aims to address this gap, conducting since 2013 a series of intervention studies together with the care centre for torture and war survivors Hemayat in Vienna (Austria). The research analyses effect mechanisms in order to contribute to the understanding of the therapeutic processes and outcomes of sport, exercise and movement with torture and war survivors. This lecture focuses on the results regarding the self-experiencing processes through the active and bodily participation and the group-experiencing processes as specific aspects of the sport and exercise therapy; it also debates research challenges and complementary effects with other therapies, e.g. with art therapy. Finally it discusses the role of sport and exercise in the framework of trauma work with people forced to cross borders, highlighting concrete ways to cross disciplinary borders in research and to foster complementary work.

EXERCISE AS MEDICINE: FOCUS ON THE EFFECT OF INTERVAL-WALKING IN THE TREATMENT OF PATIENTS WITH TYPE 2 DIABETES

PEDERSEN, B.K.

Rigshospitalet and University of Copenhagen

Type 2 diabetes mellitus (T2DM) is associated with metabolic dysregulation and chronic inflammation, and regular exercise provides a strong stimulus for improving both. It has been known for many years that peripheral tissue glucose disposal is increased and blood glucose is lowered in subjects with T2DM after an exercise session under carefully controlled, laboratory conditions. Furthermore, solid evidence that physical activity improves glycemic control in T2DM subjects, but only if the exercise is supervised. Given the global burden of T2DM, it is necessary to develop new exercise training regimes that can be incorporated in the daily life of this patient group. We have shown that 4 months of free-living interval-walking (IW) training improves glycemic control more than energy expenditure- and time duration-matched continuous-walking (CW) training in T2DM subjects. Moreover, VO_2max increased in the interval-walking group, whereas no changes were observed in the continuous-walking or control group. Body mass and adiposity (fat mass and visceral fat) decreased in the interval-walking group only. While waiting for the outcome of long-term randomized clinical training studies with hard end points, it should be emphasized that physical activity represents a natural strong anti-inflammatory and metabolism-improving strategy with minor side effects and that IW training may be a way to stimulate physical activity in patients with T2DM.

RIBOSOME BIOGENESIS IN HUMAN SKELETAL MUSCLE WITH CONCURRENT TRAINING COMPARED WITH SINGLE-MODE RESISTANCE TRAINING

FYFE, J.J.1, BARTLETT, J.D.1,2, HANSON, E.D.1,3, ANDERSON, M.J.1, GARNHAM, A.P.1, BISHOP, D.J.1, STEPTO, N.K.1

Victoria University

1: ISEAL, Victoria University, Australia; 2: Western Bulldogs Football Club, Australia; 3: University of North Carolina, USA Introduction: Previous work (1,3) suggests interference to resistance training (RT) adaptations following concurrent training is not mediated via attenuated post-exercise increases in translational efficiency (i.e., mTORC1 signalling). Recent information has emerged on the regulation of translational capacity (i.e., ribosome biogenesis) with RT-induced skeletal muscle hypertrophy (2). We examined markers of ribosome biogenesis in skeletal muscle after concurrent training, incorporating either high-intensity interval training (HIT) or moderate-intensity continuous training (MICT), vs. RT performed alone. Methods: 23 active men (mean \pm SD: VO_2peak , $44 \pm 11 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) completed 8 wk (3 sessions/wk) of either 1) HIT cycling and RT (HIT+RT group, n=8), 2) MICT cycling and RT (MICT+RT group, n=7) or 3) RT only (RT group, n=8). After training, a single-bout exercise trial was performed to measure post-exercise molecular responses in skeletal muscle in a training-accustomed state. Vastus lateralis muscle biopsies were obtained at rest pre- and post-training, and 1 h and 3 h after the single-bout exercise trial. Results: Training-induced changes in markers of ribosome biogenesis, including expression of the 45S rRNA (ribosomal RNA) precursor (~75%), and mature rRNA species 5.8S (~125%) and 28S (~75%) were greater for both MICT+RT and HIT+RT vs. RT, mirroring the larger increases in total RNA content (~27-47%). A single bout of RT performed post-training further increased the phosphorylation of p70S6K1 Thr389 (~50%) and regulators of 45S rRNA transcription, TIF-1A Ser649 (~52-75%) and UBF Ser388 (~49-64%) vs. concurrent exercise. The training-induced increase in type I muscle fibre cross-sectional area was attenuated for HIT+RT vs. RT (~34%), but was not related to changes in total skeletal muscle RNA content. Discussion: Training-induced increases in rRNA expression and total RNA content were greater with concurrent training vs. RT alone, suggesting enhanced ribosome biogenesis. This was despite RT preferentially inducing skeletal muscle mTORC1 and ribosome biogenesis signalling compared with concurrent exercise, when performed in a training-accustomed state. Together, these data suggest skeletal muscle ribosome biogenesis is not impeded with concurrent training, and that altered ribosome biogenesis does not appear to mediate interference to RT adaptations after short-term (8 wk) concurrent training. RIBOSOME BIOGENESIS AND INDIVIDUAL RESPONSES TO STRENGTH-TRAINING OF LOW AND MODERATE VOLUME

HAMMARSTRÖM, D., RØNNESTAD, B.R., BLOMSTRAND, E., WHIST, J.E., ELLEFSEN, S.

a, Lillehammer University College, Lillehammer Norway; b, GIH, The Swedish School of Sport and Health Sciences, Stockholm Sweden; c, Innlandet Hospital Trust, Lillehammer Norway.

Introduction Adaptive responses to a standardized strength training-program varies substantially between individuals. To maximize training efficacy, individualization is often necessary, typically achieved by manipulating exercise-training variables such as frequency, intensity and volume. Previous studies of effects of within-session training-volume on muscle hypertrophy and strength gains show benefits of multiple-sets per exercise [1,2], however without exploring an individual perspective. Recently, ribosome biogenesis was proposed as a key determinant for muscular hypertrophy [3]. The aim of the present study was to characterize individual variation in responses to 12 wk of strength-training of low and moderate training volumes, and to explore RNA abundance, a marker of ribosome abundance as a determinant for tolerance to increased training volume. Methods Thirty-four previously untrained male (n=16, (mean \pm SD) age 24 ± 4 yrs, height 183 ± 6 cm and weight 76 ± 11 kg) and female (n=18, 22 ± 1 yrs, 168 ± 7 cm, 64 ± 10 kg) participants completed a unilateral strength training-program three times per wk for 12 wks consisting of three exercises (leg-press, leg-curl and knee-extension)

of low (1-set per exercise, 1S) and moderate (3-sets per exercise, 3S) training volume allocated to either leg in a within-participant design. Knee-extensor 1RM and muscle cross-sectional area (CSA) assessed was determined before and after the intervention. Bilateral biopsies sampled at rest from m. vastus lateralis pre-training and after five sessions were used to determine total RNA abundance. Results 3S led to greater improvements than 1S in maximal strength ($46.5 \pm 22.4\%$ vs. $42 \pm 19.3\%$, $p=0.007$) and muscle CSA ($5.1 \pm 3.8\%$ vs. $3.7 \pm 3.8\%$, $p=0.006$). 24 out of 34 benefited more from 3S. This coincided with greater increases in total RNA after five training-sessions in the three-set leg in responders to 3S compared to responders to 1S (1.38 ± 0.51 vs. 1.14 ± 0.17 fold-change from baseline, $p<0.05$) with no differences in the one-set leg. Discussion This study demonstrates high inter-individual variations in adaptive responses to strength-training of different training-volumes. The results suggest that the ability to benefit from greater training volumes during a 12 wk training program is somehow connected with the ability to increase abundances of ribosomes during the initial part of the program. PROLONGED EXERCISE DURING CALORIC RESTRICTION AMPLIFIES MITOPHAGY-SIGNALING IN THE EXERCISED MUSCLES AND INCREASES FAT OXIDATION

MARTIN-RINCON, M.I., PEREZ-LOPEZ, A.I., PEREZ-SUAREZ, I.I., MORALES-ALAMO, D.I., LOSA-REYNA, J.I., PONCE-GONZÁLEZ, J.G.I., DE PABLOS-VELASCO, P.I., HOLMBERG, H.C.3, CALBET, J.A.1

1IUIBS, Univ of Las Palmas de GC and 2Alcalá de Henares, Spain; 3SWSRC, Mid Sweden Univ, Sweden

INTRODUCTION Mitochondria are continuously damaged by ROS. To avoid disease, dysfunctional mitochondria must be recognized and targeted for degradation by a specific mode of autophagy, named mitophagy. Exercise stimulates mitochondrial biogenesis (PGC1 α) and fusion (mitofusin, Mfn), as well as mitophagy (BNIP3) to enhance mitochondrial quality. PGC1 α is reduced and mitophagy increased with starvation. How exercise and starvation interact remains unknown in humans. Thus, we aimed to determine the impact of the amount of exercise in mitophagy during severe energy deficit in skeletal muscles (sm) submitted to two levels of exercise (8h/day and 45 min/d) or no-exercise. We hypothesized that exercise will blunt PGC1 α and enhance mitophagy responses to starvation. METHODS Fifteen overweight men underwent 4 days of caloric restriction (CR) (0.8 g/kg BW/day of either whey n=8 or sucrose n=7) and prolonged exercise (PE) (45min of one-arm cranking and 8h walking/day). Muscle biopsies from both deltoid and one vastus lateralis (VL) were taken before (PRE), after PE+CR and following 3 days of control diet (isoenergetic) and reduced exercise (CD); and sm AMPK, PGC1 α , SIRT3, MUL1, Mfn2 and BNIP3 expressions were analyzed by WB. Maximal fat oxidation (MFO) was determined by indirect calorimetry and body composition using DEXA. Statistical analysis was performed using repeated-measures ANOVA. RESULTS The energy deficit was 5000 Kcal/d during PE+CR. Compared to PRE, Mfn2 expression was reduced (-24%), and BNIP3 and MUL1 increased (93-97%) in VL after CD. In the exercised and non-exercised deltoid, Mfn2 and MUL1 did not change significantly, while BNIP3 was increased (+52%, $P<0.05$). PGC1 α and SIRT3 (mitochondrial protein) were similarly reduced and Thr172-AMPK phosphorylation increased, in both deltoid and VL. Responses were similar for the whey and sucrose groups. MFO was increased, and changes in MFO and BNIP3 were associated ($r=0.21$, $P=0.05$). DISCUSSION AND CONCLUSIONS Severe energy deficit was associated with reduced mitochondrial biogenesis and mitochondrial proteins in the three sm, regardless of the amount of exercise. Mitochondrial fusion was reduced and mitophagy stimulated, with this effect being greater in VL, indicating that a higher exercise amount during starvation amplifies the mitophagic response in the exercised sm. Increased mitophagy was associated with increased MFO. Protein ingestion did not attenuate mitophagy stimulation during starvation. Exercise did not attenuate the reduction in mitochondrial biogenesis elicited by starvation. Grant: MINECO PI14/01509

LOAD-INDUCED TYROSINE 397 PHOSPHORYLATION OF FOCAL ADHESION KINASE WITH RESISTANCE TRAINING IS MUSCLE REGION AND CONTRACTION-TYPE SPECIFIC

FRANCHI, M.V., RUOSS, S., SMITH, K., ATHERTON, P.J., NARICI, M.V., FLÜCK, M.

University of Nottingham

We previously showed that concentric (CON) vs. eccentric (ECC) type of exercise (matched for relative maximum load) leads to muscular hypertrophy through different anatomical adaptations. (1,2). Since FAK activation, measured by the proxy of Y397 phosphorylation (i.e. pY397-FAK), increases within minutes after muscle contraction and in proportion to muscle tension, we assessed whether the differences in muscle architectural responses to ECC and CON resistance training (RT) were associated with changes FAK content and in the specific Y397 phosphorylation of FAK (i.e. pY397-FAK / FAK). We hypothesized that the concentration and Y397 phosphorylation of FAK in response to training differ between contractions and between mid and distal muscle regions, reflecting distinct architectural adaptations. Four healthy young subjects (25.3 ± 7.2 years, BMI, 24.3 ± 3.6) carried out unilateral CON and ECC RT on a leg press machine i.e. each leg performing $4 \times 8-10$ reps at 80% CON or ECC 1-RM, $3 \times$ wk., for 4-wks (as per 3). Vastus lateralis (VL) muscle biopsies were collected within 60-90 minutes post exercise from the mid-belly and distal (4 cm above the myotendinous junction) portions of the VL muscle at 0 and 4 weeks of RT and analyzed for concentrations of FAK, pY397-FAK and pY397-FAK/FAK. Results were analyzed with a repeated ANOVA with Bonferroni's post hoc test. Correlations were tested with linear regression analysis. Although training produced similar hypertrophic responses (muscle thickness CON: +8.4 %; ECC: +7.6 %), these were attained through distinctly different architectural adaptations after ECC and CON training (i.e. greater fascicle length in response to ECC whereas greater increase in PA following CON RT) (3). The different anatomical changes with the two types of RT were reflected by exercise-specific and region-specific ($p<0.05$) alterations in specific Y397 phosphorylation of FAK post exercise and FAK concentration with RT. This difference was associated with an enhanced level of pY397-FAK / FAK in the distal compared to the mid-belly region post eccentric exercise ($P<0.05$), CON did not affect FAK concentration and specific Y397 FAK phosphorylation. At 4 weeks, FAK concentration positively correlated with Lf ($r=0.65$) and MT ($r=0.58$), whereas a negative correlation was found with PA ($r=-0.57$), suggesting that FAK could be linked to muscle remodeling mechanisms in response to different mechanical stimuli. Changes in pY397-FAK- concentration correlated with the work performed during maximal voluntary contraction ($r=0.62$). Collectively, the data highlight that the specific Y397 phosphorylation of FAK in the VL muscle is modified by training in proportion to the impacting force and region subjected to the highest degree of loading. Site-specific changes in pY397-FAK, and FAK content may play an important role in architectural adjustment of knee extensor muscle in response to CON vs. ECC training. 1)Reeves et al. Exp Phys 2009 2)Franchi et al. Acta Phys 2014 3)Franchi et al. Phys Rep 2015

INTERLEUKIN-15 RECEPTOR-ALPHA UPREGULATION IN SKELETAL MUSCLE BY EXERCISE AND CALORIC RESTRICTION

PEREZ-LOPEZ, A.1,2, PEREZ-SUAREZ, I.2, MARTIN-RINCON, M.2, MORALES-ALAMO, D.2, LOSA-REYNA, J.2, RODRIGUEZ-GARCIA, L.2, PONCE-GONZÁLEZ, J.G.2, DE PABLOS-VELASCO, P.L.2, HOLMBERG, H.C.3, CALBET, J.A.L.2

1 Univ of Alcalá, Spain, 2 IUIBS, Univ of Las Palmas de GC, Spain, 3 SWSRC, Mid Sweden Univ, Sweden

INTRODUCTION Overexpression of interleukin-15 (IL-15) has revealed the lipolytic, antiadipogenic and anabolic effects of this myokine. In skeletal muscle, IL-15 may act by binding to IL-15Ra, which seems to exert independent functions from those attributed to IL-15. Interestingly, deficiency of IL-15Ra or IL-15 overexpression in mice increased muscle oxidative capacity and fatigue resistance by eliciting AMPK/SIRT1/PGC1alpha signaling. However, IL-15Ra protein expression has not been studied in human skeletal muscle. Thus, we aimed to assess the potential role of skeletal muscle IL-15/IL-15Ra in the metabolic adaptations to exercise. **METHODS** Muscle biopsies were obtained from both deltoids and one vastus lateralis muscles of 15 overweight men to analyze skeletal muscle IL-15, IL-15Ra, AMPK, PGC1a and SIRT1 expressions by Western blot in three experimental phases: PRE, before; PE+CR, after 4 days of prolonged exercise (45min of one-arm cranking followed by 8h walking each day) and caloric restriction (0.8 g/kg BW/day of either whey (n=8) or sucrose (n=7)); CD, following 3 days of control diet (isoenergetic) and reduced exercise. Maximal fat oxidation (MFO) was determined by indirect calorimetry and body composition using DEXA. **RESULTS** Whole-body fat and lean mass were reduced 2.8 and 1.0 kg at CD, respectively ($P<0.05$). After PE+CR, the MFO of control arm, trained arm and leg muscles were elevated by 42%, 35% and 73%, respectively, remaining elevated at CD in all muscles ($P<0.05$). IL-15Ra protein expression increased by 8 and 11%, and Thr172-AMPK/Total AMPK by 27 and 56%, after PE+CR and CD, respectively. PGC1a protein and mRNA expressions decreased by 17% and 26% at CD ($P<0.05$). SIRT1 and IL-15 were not significantly altered. No significant differences were observed among muscles or due to the ingested solutions. Finally, changes in IL-15 and IL-15Ra were associated with changes in MFO ($r=0.21$ and 0.28 ; $P<0.05$), and the expression of IL-15 and IL-15Ra were inversely related to the proportion of myosin heavy chain type I ($r=-0.70$ and -0.93 ; $P<0.05$) and PGC1a ($r=-0.71$ and -0.79 ; $P<0.05$). **DISCUSSION** Skeletal muscle IL-15Ra was upregulated by prolonged exercise and this response was associated with elevated MFO in both exercised and non-exercised muscles. Thus, enhanced IL-15/IL-15Ra signaling may be involved in the metabolic adaptation of exercised and resting human skeletal muscles to a negative energy balance. The inverse relationship between PGC1a and IL-15Ra may reflect involvement of IL-15/IL-15Ra in the regulation of mitophagy and protein breakdown. Grant: MINECO PI14/01509

FIBRE-TYPE DEPENDENT ACTIVATION OF HUMAN MUSCLE CA₂₊ AND ATP-SENSITIVE SIGNALLING PATHWAYS BY EXERCISE IS MODIFIED BY ISCHAEMIA: ROLE IN FIBRE-TYPE SPECIFIC GENE REGULATION

CHRISTIANSEN, D., MURPHY, R.M., BISHOP, D.J.

Victoria University, Melbourne, VIC 3011; La Trobe University, Melbourne, VIC 3086

Skeletal muscle function is preserved or improved by exercise training. This may in part be ascribed to repeated, transient bursts in gene expression that accompany consecutive bouts of exercise (2). Activity-induced oscillations in cytosolic Ca₂₊ and ATP turnover have been linked to the activation of signalling cascades regulating muscle adaptation (1, 3). These cellular signals can be manipulated during exercise by decreasing muscle perfusion (ischaemic) or arterial oxygen saturation (hypoxia). These exercise models were used to examine the association between fibre-type dependent regulation of Ca₂₊ and ATP-sensitive signalling pathways and fibre-type specific gene transcription. Eight trained males (26 ± 5 y and 57.4 ± 6.3 mL·kg⁻¹·min⁻¹) completed three interval running sessions with (IT) or without ischaemia (CT), or in hypoxia (HT), in a randomised, crossover fashion separated by 1 week. A muscle sample was collected from both the ischaemic and control leg in IT, and from the dominant leg in CT and HT, before (Pre) and after exercise (+0h, +3h). Muscle fibres (n = 2600) were fibre-typed and grouped into type I and II fibres for immunoblotting to determine the phosphorylation of CaMKII, AMPK, ACC, MAPK and phospholamban (PLB), and for RT-PCR to quantify changes in expression of mitochondrial (PGC-1α) and ion transport (Na⁺-K⁺-ATPase) genes. p-ACCSer221/ACC increased in type II fibres at +0h in all conditions ($p < 0.05$); in type I fibres there was a greater increase at +0h in the ischaemic leg compared to CT, HT, and the control leg. p-PLBThr17/PLB increased in type II fibres in the ischaemic ($p < 0.05$), but not control, leg in IT. No change in this ratio was found in type II fibres after CT and HT, whilst it increased in type I fibres after all conditions ($p < 0.05$). Both p-CaMKII γ/δThr287/CaMKII and p-CaMKII β/MThr287/CaMKII was higher in type II vs. type I fibres at Pre and +0h ($p < 0.05$). p-CaMKII γ/δThr287/CaMKII in type II fibres decreased after CT ($p < 0.05$), but not after IT and HT, whilst p-CaMKII β/MThr287/CaMKII remained unchanged. Phosphorylation of p44/42 (Erk1/2) MAPKThr202/204/MAPK increased ($p < 0.05$) in both fibre types at +0h, with no differences between conditions. We demonstrate that contraction-stimulated activation of human muscle Ca₂₊ and ATP signalling pathways is fibre-type dependent and can be modified by ischaemia. This is likely to induce differential exercise-induced gene transcription in type I and II fibres, which may be important to the overall muscle adaptive response to exercise training. Fibre-type specific gene expression is currently being analysed and will also be presented. 1. Kristensen et al. Human muscle fibre type-specific regulation of AMPK.. J Physiol, 2015. 2. Perry et al. Oral presentations**OP-PM15 Performance & Water****THE RELATIONSHIP BETWEEN POWER THRUST AND POWER DRAG IN ELITE SHORT DISTANCE SWIMMERS**

ZAMPARO, P., CORTESI, M., GATTA, G.

University of Verona

Introduction At constant average speed (v), a balance between thrust force (F_t) and drag force (F_d) should occur: F_t-F_d = 0 (Toussaint et al. 1992); hence power thrust (P_t = F_t v) should be equal to the power needed to overcome drag forces at that speed (P_d = F_d v); the aim of this study was to measure P_t (full tethered swims) and to estimate P_d in active conditions (at sprint speed) and to compare these values. Methods Ten front crawl elite swimmers (male; 23.5 ± 3.4 years; expertise $93.1\% \pm 2.4$ of 50 m world record) participated to the study; their sprint speed was measured during a 30 m all-out trial. F_t was assessed during a 15 s full-tethered effort (Keskinen et al. 1989);

passive towing measurement were performed to determine speed specific drag in passive conditions (kP = passive drag force / v^2); drag force in active conditions ($F_d = kA v^2$) was calculated assuming that $kA = 1.4 \text{ kP}$ (Gatta et al. 2015). Results Average sprint speed was $2.20 \pm 0.07 \text{ m}\cdot\text{s}^{-1}$; kA , at this speed, was $34.7 \pm 2.5 \text{ N}\cdot\text{m}^{-2}\cdot\text{s}^{-2}$. A strong correlation between power thrust ($399 \pm 56 \text{ W}$) and power drag ($374 \pm 53 \text{ W}$) was observed: $Pd = 2.35 + 0.929 \cdot Pt$, $R^2 = 0.953$, $N = 10$, $p < 0.001$. The Bland-Altman level of agreement was generally less than $\pm 1.96 \text{ SD}$, the mean difference ($\pm \text{SD}$) between methods was $25.8 \pm 12.2 \text{ W}$. Discussion In this study, the swimmer power for propulsion was calculated as a product of force and velocity using two different methods. This evaluation shows that the power thrust values have a high degree of agreement with the (active) power drag values and this support the use of the full tethered test as an accurate, reliable test to compute the power propulsion of a swimmer. WINTER SWIMMING - HEALTHY OR HAZARDOUS?

ZEMAN, V., RACEK, J., RAJDL, D., TOPOLCAN, O., NOVAK, J., TRDLICKOVA, P.

Faculty of Medicine

INTRODUCTION WS is swimming in natural water at a temperature (T_w) under 8°C . WS has been known for many years as a non-competitive event. Recently, however, competitions in WS have been organized. Swimming produces heat. However it also causes vasodilation in the body surface area and in active muscles and also cold water streams along the body. That's why the body cooling is greater. Protection against heat losses is possible in two ways: A extension of the isolative ability of the body and B thermogenesis. A. Vasoconstriction appears in skin and subcutaneous tissue and in inactive muscles. During the long-term cold adaptation higher subcutaneous fat thickness occurs. B. Thermogenesis is possible due to muscle activity and shivering. The most effective form is the non-shivering thermogenesis induced due to NE. Cooling a muscle causes its worse function. Both muscle shortening velocity and power decrease and the muscle fatigue arises earlier. The cold activates the sympathetic nervous system. NE increases the BP, FFA mobilization and leukocytosis. The pituitary – adrenal axis is also activated. Thyroid hormones are necessary for the development of the cold adaptation. NE reduces blood flow also in kidneys and GF falls (I). HEALTH RISKS Hypothermia is divided into mild (Tr 32-35°C), middle (Tr 30-32°C), and severe (below 30°C). Hypothalamus begins to lose its ability to regulate body temperature. It is completely lost when Tr falls below 29°C. In severe hypothermia the hospitalisation is necessary. Humans die when their Tr falls to 24 - 25°C. Cooling of the heart tissue leads via sinus node to a progressive decline of HR followed by arrhythmias and cardiac arrest (4). The face cooling acts similar changes via the diving reflex. Accidents and serious disorders in WS during race appear mostly independently on the grade of hypothermia. During the last decade a case of stroke and a case of coronary artery disease during competition were recorded in CR. THE POSITIVE INFLUENCE WS is an instrument for the prevention of illnesses from cold. Enhanced immunity against respiratory infection diseases developed in subjects, who regularly shower or bathe in cold water. The cause lies in a higher level of plasmatic IgA (3). WS results in increased stimulation of immune system. Organism manages then easily common situations rising as a result of a relatively slight and short-term cold exposure (2) REFERENCES 1. PRIMING EFFECTS OF WATER IMMERSION ON PAIRED ASSOCIATIVE STIMULATION INDUCED NEURAL PLASTICITY IN THE PRIMARY MOTOR CORTEX

SATO, D., YAMASHIRO, K., YAMAZAKI, Y., TSUBAKI, A., ONISHI, H., UETAKE, Y., NAKANO, S., SHIMOYAMA, Y., MARUYAMA, A.

Niigata University of Health and Welfare

Introduction Recent studies have reported cortical activation during water immersion (WI). Our previous study have shown decreased specific inhibitory circuit in the primary motor cortex (M1) modulated by cholinergic neural activity, represented by short-latency afferent inhibition (SAI) during WI (Sato et al., 2013). In terms of neural plasticity, the history of neural activity determines the sign and magnitude of subsequent synaptic plasticity (Abraham, 2006). It is possible that WI would have homeostatic aftereffects on cholinergic activity, as stronger SAI is observed after WI compared to that at baseline. In such cases, priming WI might enhance and prolong long-term potentiation (LTP)-like plasticity induced by paired associative stimulation (PAS). Methods We performed two experiments in 16 healthy participants to better understand the effects of priming WI on PAS-induced plasticity and its neural substrate. WI was performed for 15 min prior to PAS. PAS consisted of 180 electrical stimuli of the left median nerve at the wrist paired with a single pulse transcranial magnetic stimulation (TMS) over the hotspot of the left abductor pollicis brevis muscle at a rate 0.2 Hz at rest. In experiment 1, we measured corticospinal excitability by using single pulse TMS before and after priming WI and immediately, at 15 min, and at 30min after PAS. In experiment 2, SAI was demonstrated by using paired-pulse TMS protocol before, immediately, at 5 min, 10 min, 20 min, 30 min, and 40 min after WI to clarify the homeostatic aftereffect of WI on cholinergic neural activity. Results Repeated measures analysis of variance revealed a significant interaction between "priming" and "time" [$F(2,44,36,56) = 7.82$, $p < 0.05$] as well as between reliable main effects of "priming" [$F(1,15) = 38.03$, $p < 0.05$] and "time" [$F(1,843,27,51) = 5.42$, $p < 0.05$]. Post hoc comparisons revealed that after PAS session, motor evoked potential (MEP) amplitudes in the priming WI trial were significantly higher than that in the control ($p < 0.05$). Additionally, post hoc comparisons revealed that MEP amplitudes significantly increased 15 min and 30 min after PAS only in the priming WI trial ($p < 0.05$). Discussion The present results have shown that priming WI enhanced PAS-induced LTP-like plasticity. Several pharmacological studies have found that cholinergic activation enhances LTP-like plasticity induced by PAS (Kuo et al. 2007). Therefore, one possible explanation for the present results would be homeostatic increased cholinergic activity as an aftereffect of WI. References Abraham WC (2006). EFFECTS OF ACUTE UNDERWATER IMMERSION ON REFLEX EXCITABILITY

JOZEFIAK, Z., AVELA, J., WALLER, B., CRONIN, N.

University of Jyvaskyla

Introduction Water as an exercise medium creates a unique environment for both training and rehabilitation purposes (Thein and Brody 1998), but the neurophysiological effects of water immersion are poorly understood. This is at least partly due to the methodological

difficulty of implementing underwater electrical stimulation and recording. Methods We have custom-built a water tank to enable recording of underwater reflex responses during prolonged water immersion. The setup allows a high degree of control of relevant factors such as posture, muscle activity, electrical stimulation and other possible external factors that could affect the Hoffmann reflex. After recording a high resolution recruitment curve on dry land, 23 stimuli were given within a certain range to obtain H-reflex and M-responses. Stimulation output and inter-stimulus interval (ISI) were randomized based on previous recommendations (Brinkworth et al. 2007; Zehr 2002). One hour of dry land and 1 hour of water immersion have been compared - a total of 10 recruitment curves were obtained during 2 hour long sessions. The test session was repeated after 1 week. In order to determine spinal excitability changes, the following parameters have been analyzed: peak-to-peak amplitude of the maximal reflex and muscle response (Hmax; Mmax), H/M ratio; latencies of the reflex and muscle responses (Hlat; Mlat), slope of the ascending part of the H-reflex recruitment curve (Knikou 2008). Results To date, 3 healthy subjects have been tested (mean age: 25.6 ± 2.9 years; height: 177.0 ± 2.1 cm; body mass: 69.3 ± 1.7 kg), and a further 13-16 will be tested in the near future. Results so far indicate that in general, maximal H/M ratio increases immediately after water immersion. Repeatability was also high, with mean differences between time points of 3.0% in the H/M ratio and 0.3% in maximal muscle response in the dry condition. Discussion To date, no study has examined neuromuscular changes during prolonged water immersion. Our results show highly repeatable underwater recording with both EMG and H-reflex methodology. In the future, further investigation of neuromuscular changes in an aquatic environment will be conducted with different populations (e.g. elderly, stroke, and spinal cord injured patients). ESTIMATING PEAK OXYGEN UPTAKE BASED ON POSTEXERCISE MEASUREMENTS IN SUPRAMAXIMAL SWIMMING

CHAVERRI, D.1, IGLESIAS, X.1, SCHULLER, T.2, HOFFMANN, U.2, RODRÍGUEZ, F.A.1

1: INEFC-Barcelona Sports Sciences Research Group, Universitat de Barcelona (Spain), 2: Institut für Physiologie und Anatomie, Deutsche Sporthochschule Köln (Germany)

Introduction In swimming, different approaches using postexercise measurements have been used to estimate peak oxygen uptake ($\dot{V}O_2\text{peak}$), e.g. single time-bin measurements (Costill et al. 1985), $\dot{V}O_2$ backward extrapolation (BE) (Léger et al 1980), and heart rate (HR)- $\dot{V}O_2$ modelling (Chaverri et al. 2015). To assess the validity of postexercise measurements in estimating $\dot{V}O_2\text{peak}$, we compared $\dot{V}O_2\text{peak}$ measured during supramaximal swimming with that estimated using various commonly adopted techniques. Methods 31 elite swimmers performed a 200-m supramaximal swim where $\dot{V}O_2$ was measured breath-by-breath (K4 b2, Cosmed, Italy) and HR beat-by-beat (CardioSwim, Frelap, Switzerland), 1 min before, during, and 3 min post-exercise. $\dot{V}O_2\text{peak}(20-0)$ was the average of the last 20 s of effort used as a criterion. The following postexercise measures were compared: 1) first 20-s average [$\dot{V}O_2\text{peak}(0-20)$]; 2) linear and semilogarithmic BE of the first 20 s [BE(20) and LOG(20)], first 30 s, and 3x20-s, 4x20-s and 3 or 4x20-s averages; and 3) predicted $\dot{V}O_2\text{peak}$ using mathematical modelling [$p\dot{V}O_2(0-20)$]. RM-ANOVA and post-hoc Bonferroni tests compared exercise $\dot{V}O_2\text{peak}$ and estimated values. Pearson's r^2 was used to assess correlation and for double cross-validation (DCV) analysis. Results Criterion exercise $\dot{V}O_2\text{peak}(20-0)$ ($3.531 \pm SD 738$ ml·min $^{-1}$) was different from all estimated parameters investigated ($p < 0.001$) except $p\dot{V}O_2(0-20)$ (mean diff. 1.1%, $p > 0.99$), BE(20) (2.4%, $p = 0.39$), and LOG(20) (2.6%, $p = 0.30$). Additionally, $p\dot{V}O_2(0-20)$ was strongly correlated with exercise $\dot{V}O_2\text{peak}$ ($r^2 = 0.962$; DCV: $r^2 = 0.977$ and $r^2 = 0.955$, $p < 0.001$). Discussion Our results confirmed the $\dot{V}O_2\text{peak}$ underestimation reported by Chaverri et al., 2015 when using a single time-bin post-exercise measure (e.g. 20 s, Costill et al. 1995), and the overestimation reported by Lavoie et al. (1983) when BE was used in supramaximal swimming. We conclude that the new modelling procedure based on postexercise $\dot{V}O_2$ and HR measurements provides the most valid and accurate procedure for estimating $\dot{V}O_2\text{peak}$ in supramaximal swimming whilst avoiding the estimation bias produced by other methods. OP-SH02 Psychology: Sport Performance

GOLD IN EDUCATION AND ELITE SPORT: A FLEMISH PERSPECTIVE ON THE COMPETENCES OF ELITE PUPIL-ATHLETES AND STUDENT-ATHLETES.

DE BRANDT, K., WYLLEMAN, P., DEFROYT, S., TAELMAN, K.

Vrije Universiteit Brussel, *Sport Vlaanderen

Introduction. Elite athletes face challenges in different domains (i.e. athletic, psychological, social, academic and financial) during their dual 'elite sport and study' career (DC) $^\circ$. To cope with these challenges, athletes require a set of competences in order to optimize their preparation for, and development throughout their DC $^\circ$. Aim. While past research generally used a qualitative approach to identify the competences required for a successful DC $^\circ$, this study used a quantitative approach to identify the competences (i.e. skills, attitudes, knowledge, experiences) athletes require to optimally prepare, manage and finalize their 'education and elite sport' pathway. Method. The online survey of the Erasmus+ Sport project 'Gold in Education and Elite Sport', which focused on i) the importance and possession of a predefined list of 38 DC competences on a 5-point scale, and ii) the importance and use of these competences in 7 specific challenging DC situations ('DC scenarios'), was presented to 891 Flemish 15-25 year-old athletes combining elite sport and study. SPSS was used for descriptive and comparative analyses, and MPlus was used for Exploratory Structural Equation Modelling (ESEM). Results. 524 athletes (59%) responded to the survey (mean age 17.6 ± 2.3 years; 61% male athletes vs. 39% female athletes; 74% pupils vs. 26% students). While all competence items were rated as important to very important ($4.3 \pm .70$), scores for possession were significantly lower ($3.6 \pm .87$; $p < .001$) with the largest difference between importance and possession found in management of mind and emotion (e.g. coping with stress, using setbacks as positive stimulus) and life management competences (e.g. efficient use of time; conscientious pro-active planning). On average, student-athletes experienced more scenarios than pupil-athletes (respectively 4.3 and 3.4; $p < .001$). For each of

the 7 scenarios, a set of transferable competences (useable across multiple scenarios) and specific competences (needed in a specific challenging situation) was defined. Further detailed results (i.e. scenarios, inter-individual differences and the ESEM results) will be presented. Discussion. A set of competences and scenarios relevant for a DC was identified. The use of 'scenarios' guaranteed context-specificity and the identification of transferable and specific competences. DC-support providers should be aware of these transferable and specific competences in order to proactively assist and empower athletes during their DC pathway. EGO DEPLETION AND GLUCOSE INGESTION DURING ATHLETIC PERFORMANCE

BOAT, R., TAYLOR, I.M., HULSTON, C.J.

Loughborough University

Introduction According to the strength model of self-control (Baumeister et al., 1998), self-control becomes diminished when an individual regulates his/her behaviours, a state known as ego depletion. Consequently, the individual will have a reduced capacity to perform any subsequent behaviour that requires self-regulation. This study explored whether depletion effects occur in the performance of a gross motor skill endurance task that requires self-regulation in well-trained athletes. Furthermore, the study examined the potential for glucose supplementation to moderate the ego depleting effect. Methods Fourteen endurance trained cyclists completed four simulated 16 km time trials on an electromagnetically braked cycle ergometer. Prior to each time trial, participants completed an easy Stroop task or a difficult Stroop task that required self-control. They also received either a glucose-based drink or placebo. Participants' performance time and heart rate were recorded throughout the time trials. Results Multilevel growth curve analysis revealed a significant two-way interaction for glucose and self-control ($b = -29.43$; $p = 0.036$). When a placebo drink was consumed, participants performed worse in the time trial following exertion of self-control, compared to when no self-control was required. This effect was not observed when a glucose drink was consumed ($b = -7.76$; $p = 0.438$). A significant three-way interaction revealed that ego depletion effects became significant after 80% of the trial had been completed ($b = 20.20$; $p = 0.037$). Discussion The results indicate that initial self-control exertion can negatively affect subsequent performance in well-trained endurance athletes as they perform highly practiced behaviour. In addition, the results suggest that the supplementation of glucose during a physical sports task that requires self-regulation can negate the ego depleting effect. However, this moderating effect may only manifest in longer duration endurance performances. The results provide support for the viability of utilising the strength model of self-control to understand self-regulation failures within athletic performance environments. The findings help understand the relationship between cognitively demanding acts and subsequent highly practiced endurance performance. NARCISSISM AND PERFORMANCE UNDER STRESS: EVERY PIECE OF NARCISSISM MATTERS

ZHANG, S., ROBERTS, R., WOODMAN, T., HARDY, L.

Institute for the Psychology of Elite Performance, Bangor University

Introduction Narcissists thrive under stress as stressful environments provide the narcissist with an opportunity for personal glory (Wallace & Baumeister, 2002). Previous work in this area has only focused on narcissistic grandiosity as a typical trait of arrogance and entitlement seeking. However, evidence has highlighted that grandiosity is multidimensional (containing adaptive and maladaptive components), and the influence of each of these in relation to performance is unknown. Therefore, the aim of the study was to provide a more detailed understanding of the narcissism-performance relationship by examining the potential interaction effect between adaptive and maladaptive narcissism. Method Sixty experienced male basketball players ($M_{age} = 21.87$, $SD = 2.13$) completed measures of narcissistic grandiosity (NPI-16) and performed a free throw task under low (individual session) and high stress (group competition). We measured anxiety in each condition using the CSAI-2R. Results Moderated regression analyses revealed a significant interaction between adaptive and maladaptive components of grandiose narcissism ($\Delta R^2 = .06$, $F = 5.14$, $\beta = .28$, $p = .03$). Adaptive narcissism was positively related to performance only when maladaptive narcissism was high ($\beta = .78$, $p < .01$); maladaptive narcissism was positively related to performance only when adaptive narcissism was high ($\beta = .42$, $p = .08$). Discussion Every piece of narcissism is essential to achieve the highest performance under stress though different dimensions of narcissism contribute differently. This finding may advance our understanding of individual differences' influence on performance. Future research would do well to clarify these effects and identify the potential underlying mechanism. References Wallace, H. M., & Baumeister, R. F. (2002). The performance of narcissists rises and falls with perceived opportunity for glory. *Journal of Personality and Social Psychology*, 82(5), 819-834.

WHAT SUPPORTS PEOPLE WITH MENTAL HEALTH PROBLEMS TO PARTICIPATE IN SPORT CLUB PROGRAMMES? A QUALITATIVE APPROACH

RUF, W., HEIMGARTNER, A., TITZE, S.

Institute of Sport Science

Introduction Quality of life among people with mental health problems can be improved through physical activity (Rosenbaum et al., 2014). In an Austrian pilot study, the majority of people with mental health problems reported that they are less active than they would like to be. Although sports clubs are widespread in Austria, it is assumed that their structures are inappropriate for this vulnerable group. Therefore, we studied among people with mental health problems and their trainers whether structures in sport clubs meet the needs of this target group. Methods For this study, individuals of the target group were eligible if they stayed at least once in a psychiatric hospital and attended the "Pro Move" physical activity program run by a mental health NGO at least once a month since 2013. Semi-structured interviews were undertaken with 15 people (2 women) with a mean age of 36.7 ($SD=11.8$) and a mean body mass index of 27.6 ($SD=5.6$) and 11 trainers of European sport club associations who offer sport programs for that target group were asked to complete a questionnaire. The data were transcribed and relevant paragraphs were assigned to categories related to structures in sport club by using a Grounded Theory approach (Strauss & Corbin, 2010) Results Trainers considered two options of how to structure physical activity programs for people with mental problems. The first option was that sport clubs should offer courses provided specifically for this target group. This is also preferred by many of the interviewed persons with mental health problems, as they reported experiencing an increased feeling of well-being and understanding in the own peer group. The second option was that people with mental health problems should participate in open courses eligible for the general population. For the target group this is feasible only if there is an existing

atmosphere of trust and well-being, which is strongly connected to the mental health literacy of trainers. Discussion In Austria, there is a gap between the readiness of people with mental health problems for physical activity and the provision of appropriate measures by sport clubs. Therefore, it is suggested that a case manager who is educated in sport and social care, is placed in sport clubs. Alternatively, regular meetings among the participants with mental health problems who attend a sport club programme should be established together with social care worker and the trainer. A LONGITUDINAL EXAMINATION OF ELITE ATHLETE WELL-BEING

CLANCY, R., HERRING, M.P., CAMPBELL, M.

University of Limerick

Introduction Elite athletes operate in demanding environments that consistently stretch their physical, psychological and emotional limits, and increase susceptibility to maladaptive behaviours/outcomes (e.g., disordered eating, burnout), reinforcing the need for ongoing psychological monitoring. Subjective measures of mood and mental health can be particularly useful tools, which may be indicative of future performance and provide guidance for titrating training load. Thus, this study characterised the mood and mental health profile of elite athletes, longitudinally examined these outcomes and their interrelations, and explored potential moderators (e.g., type of sport, gender, and age). Methods Elite team sport athletes (N=136) aged 18-37 years (23.21 ± 4.56) with an average of 12.77 ± 5.13 years sport experience were assessed using psychometric inventories over a 13-week period (compliance = ~94%). The sports represented were basketball, Gaelic football, field hockey, hurling, rowing, rugby, and soccer. Outcomes included the Profile of Mood States-Brief and Quick Inventory of Depressive Symptomatology (QIDS), administered weekly, and the Pittsburgh Sleep Quality Index (PSQI) and the trait subscale of the State-Trait Anxiety Inventory (STAI-Y2), administered every four weeks. Missing data was accounted for using Last Value Carried Forward imputation. Results The average Total Mood Disturbance (TMD) was 4.3 ($SD=8.7$), which is lower than that of similarly-aged Americans (26.1 ± 15.9 , Yeun & Shin-Park, 2006). 18.4% of athletes were classed as having mild depression across the 13 weeks (QIDS=6.3). 39.7% and 7.4% of athletes were categorised as poor quality sleepers (PSQI>5) and highly trait anxious (STAI-Y2>50), respectively. Nine of the ten athletes who were highly trait anxious and 19/25 athletes with mild depression were also poor sleepers. There was a significant difference in TMD for Gaelic (1.4 ± 7.6) and non-Gaelic (5.6 ± 8.7) sports ($t134=2.62$, $p \leq 0.01$). There were no significant differences by gender or five-year age group for any outcome. Discussion Measures of mood and mental health change and influence each other among elite athletes over a 13-week period. Monitoring such outcomes appears to be informative, as those with maladaptive behaviours (e.g., poor sleep quality) can be identified for intervention. Subjective measures of mood and mental health outcomes are easy to administer and may prove useful to guide training load adjustments and indicate future performance among team sport athletes. MENTAL TOUGHNESS IN PARALYMPIANS

POWELL, A.J., MYERS, T.D.

Newman University Birmingham

MENTAL TOUGHNESS IN PARALYMPIANS 1: NUB (Newman University, Birmingham) Mental Toughness (MT) has been described as a unidimensional construct that can vary across contexts and is important for performance, goal progress, and thriving despite stress (Guccardi et al., 2015). Martin et al. (2011) reported that athletes with disabilities demonstrate stronger resiliency and self-efficacy skills than able-bodied athletes. It can be assumed that athletes with disabilities have had to overcome potentially far more hardship than non-disabled counterparts, particularly in their non-sporting life. These experiences may provide insight into the development of MT. The aim of this study was to investigate MT and its development in disability sport by exploring the perceptions and experiences of Paralympic athletes. Methods A purposeful sample of elite Paralympic athletes (n=5) and coaches (n=1) were selected. The participants all competed at London 2012. Using semi-structured interviews in accordance with Smith et al. (2009), all participants were questioned about their perceptions and experiences of MT and its development in Paralympic athletes. Interviews were transcribed verbatim. Data were analysed thematically using Interpretive Phenomenological Analysis with trustworthiness established using bracketing and member checking. Results A number of characteristics associated with MT for Paralympic athletes were identified, including: confidence, hardness, optimism and the use of specific mental skills. Overcoming daily life challenges, demonstrating independence and the ability to deal with pain were seen as important in MT development. Discussion Findings highlight that critical incidents and personal adversity has facilitated the development of key mental characteristics. One possible reason is many athletes with disabilities have experienced a major life trauma, and as such may differ from athletes without disabilities on various coping skills, levels of optimism, or other important self-perceptions (Martin et al., 2011). It is conceivable that athletes with disabilities may rely on mental skills developed without formal input, perceived innate psychological strengths and affective strengths (e.g. optimism) to facilitate training and performance. Our findings highlight the association between the adaptive development of personal characteristics and overcoming physical and mental setbacks over a sustained time period, similar to previous findings (Guccardi et al., 2015). Overall, the findings suggest that athletes would benefit from exposure to demanding situations to develop superior coping skills and MT. OP-SH25 Children & Physical Exercise

EFFECT OF A SIX WEEK ACTIVE PLAY INTERVENTION ON PRESCHOOL CHILDREN'S FUNDAMENTAL MOVEMENT SKILL COMPETENCE: A CLUSTER-RANDOMISED CONTROL TRIAL

FOULKES, J.D.1, KNOWLES, Z.1, FAIRCLOUGH, S.J.2, STRATTON, G.3, O'DWYER, M.4, RIDGERS, N.D.5, FOWEATHER, L.1

Liverpool John Moores University

1: LJMU (Liverpool, UK), 2: SU (Swansea, UK), 3: EHU (Ormskirk, UK), 4: ECI (Dublin, Ireland), 5: DU (Victoria, Australia) Introduction The development of fundamental movement skill (FMS) competence promotes positive trajectories of physical activity, fitness and weight status (Robinson et al., 2015). However, evidence suggests that preschool children have low competency (Foulkes et al., 2015). This study examined the effectiveness of an active play intervention on FMS amongst 3- to 5-year-old children from deprived communities in NW England with the aim to inform local policy and educational practices. Methods In a cluster randomised controlled trial, 12 preschools were randomly assigned to either control (n=6) or intervention (n=6) groups. The intervention was implemented by a Local Authority, involving the training of preschool educators and provision of a 6-week Active Play programme; control schools followed usual practice. Data were collected at baseline (T0), post-intervention (T1) and at 6-month follow-up (T2). FMS were assessed using the Children's Activity and Movement in Preschool Study Motor Skills Protocol (Williams et al., 2009). Data were analysed using 2-level multi-level modelling (school, child), adjusted for baseline values of the outcomes and potential confounders. Differences in intervention effects by sex were also explored. Results Of 240 eligible children at baseline, 162 (68%) completed FMS assessments and were included in the final analyses (age Mean = 4.64 ± 0.58 ; 53.1% boys). Participant numbers decreased to 133 (55.4%) at T1 and 113 (47.1%) at T2. There were no significant differences between groups for total (T1: $\beta=1.45$, 95% CI -0.34 to 3.24; T2: $\beta=0.31$, 95% CI -1.31 to 1.93), object-control (T1: $\beta=1.01$, 95% CI -0.22 to 2.24; T2: $\beta=0.48$, 95% CI -1.07 to 2.03) or locomotor (T1: $\beta=0.46$, 95% CI -0.90 to 1.82; T2: $\beta=0.12$, 95% CI -0.93 to 1.17) scores. Conclusions This is the first study to examine the effectiveness of an intervention to promote FMS competency among young children from England. The results suggest that this Active Play intervention may have needed to run for longer and/or with a greater frequency of session delivery in order to be effective. Further, preschool staff may require additional training and support to promote FMS development. EFFECTS OF SCHOOL BASED EXERCISE INTERVENTION ON MOTOR PERFORMANCE, BLOOD PRESSURE AND ARTERIAL COMPLIANCE IN CHILDREN

KETELHUT, S., HACKE, C., KETELHUT, K.

Martin-Luther-Universität Halle-Wittenberg, Otto-von-Guericke-Universität Magdeburg, University Medical Centre Hamburg-Eppendorf, SRH Hochschule für Gesundheit Gera

Introduction: It is widely accepted, that sedentary lifestyle impairs motor performance (MP) and increases blood pressure (BP) in the young. Even though increased BP may lead to structural changes in vessels already at early age (Berenson et al., 1998), research assessing exercise effects on vascular function in children are spars. The present study aimed to evaluate the effectiveness of an exercise intervention (EI) on MP and BP but moreover on established markers of arterial compliance (AC). Methods: 105 students (mean age 8.2 ± 0.6 yr; 51% girls; BMI 17.8 ± 3.0 kg/m²) were randomized into intervention (IG) (N = 51) and control (CG) (N = 54) group. During a 37-week experimental period the IG received an additional EI (2x45min per week) on top of the regular school physical education class (3x45min per week). Apart from a MP-test ('CHECK!'), peripheral (pBP) and central (cBP) blood pressure, augmentation pressure (AP) and aortic pulse wave velocity (aPWV) were assessed non-invasively using Mobil-O-Graph (24 PWA monitor, IEM Stolberg, GERMANY). Multilevel linear models with random effects for schools and classes were used to analyze the effectiveness of the EI. Differences between the mean change of the outcome variable in the IG and CG were adjusted for confounders (age, sex, height and the variable at baseline). Results: There was a significant difference in the mean improvement in endurance performance (62.02 ± 168.09 m; p < .001), AP (-2.34 ± 7.47 mmHg; p = .007) and aPWV (-1.95 ± 0.718 m/s, p = .037) throughout intervention period, favoring IG. Furthermore the EI induced a significant decrease in peripheral (-4.34 ± 11.84 mmHg) and central (-3.93 ± 8.94 mmHg) systolic BP, AP (-1.67 ± 3.73 mmHg) and aPWV (-0.18 ± 0.35 m/s) in the children. Discussion: Already in children a school based EI had beneficial effects not only on endurance performance but moreover on aPWV and AP, as important determinants of left ventricular function and coronary blood flow (Gatzka et al., 1998). These positive effects may be due to an exercise induced improvement in endothelial function and vasoactive substances (Beck, et al., 2013). Based on the findings it seems advisable to increase regular physical activity in early childhood to positively influence cardiovascular risk profile. Future research should focus not only on BP but moreover on parameters of AC displaying higher prognostic value for cardiovascular morbidity (Roman et al., 2007). TRAINING IN THE MATRIX: INTRODUCING A COMBINED PROGRAM FOR YOUTH SOCCER PLAYERS DEVELOPMENT

ZAGO, M.1, SFORZA, C.1, GIURIOLA, M.2

1: University of Milan (Italy), 2: University of Pavia, FC Internazionale Milano (Italy)

INTRODUCTION High-intensity technical actions heavily influence the outcome of soccer matches. While performance factors are traditionally trained separately, we proposed a program combining technique and agility (combination of strength, speed, balance and coordination, (Sheppard and Young (2006)) for youth players' development. We assessed the effect of this program on motor and technical skills. METHODS The program was structured on a 14x12-m matrix of elastic tapes (lifted at 25 cm) that provides a constraints-driven reference for movement timing and techniques. Practices were aimed to develop game-like high-intensity technical actions with the ball.

Twenty U12 sub-elite male soccer players (41.8 ± 7.1 kg, 1.55 ± 0.08 m) from the same club were randomly assigned to an experimental (EG) and a control group (CG). A repeated-measures design was used: the EG was exposed to 20-40 min/session of differentiated training (22 weeks, 38 sessions) while the CG continued the traditional training. Shuttle Dribbling Test (SDT, Huijgen et al. (2010)) and the Loughborough Soccer Passing Test (LSPT, Ali (2011)) were performed before and after the differentiated training. Medians and interquartile ranges (IQR) of percentage change between measurements, correlation coefficients (r) with individuals' stature increments and Cohen's d effect size were computed. RESULTS The stature increment between measurements was 3.5 (IQR 0.1) cm for the CG and 3.8 (0.2) cm for the EG ($d=0.11$). In the SDT, the EG improved by 4.1%, while the CG performance decreased by 0.6% ($d=0.97$); in the LSPT, EG improved by 6.8% while the CG by 0.3% ($d=0.78$). Performance and stature changes were moderately-to-low correlated (CG vs. EG): $r=0.35$ vs. -0.17 (SDT); $r=0.41$ vs. 0.18 (LSPT). DISCUSSION The matrix was designed to stress dynamic balance, quick changes-of-direction, and specific agility/coordination skills: the program produced higher performance improvements, compared to traditional training, in 180°-changes-of-direction and in a controlling and passing dynamic task. It seemed to balance the losses in coordination caused by the adolescent motor awkwardness (Quatman-Yates et al., 2012). The program acts simultaneously on the physical, technical and perceptual corners of soccer performance, thus optimizing the training process. Despite more age/proficiency levels have to be considered, the methodological implications of this study could be beneficial for youth training effectiveness.

DETERMINANTS OF ORGANIZED PHYSICAL ACTIVITY PARTICIPATION DURING THE TRANSITION FROM CHILDHOOD TO ADOLESCENCE IN GERMANY: THE NATIONWIDE KIGGS COHORT STUDY

MANZ, K., KRUG, S., SCHIENKIEWITZ, A., FINGER, J.

Robert Koch-Institut

Introduction Organized physical activities (OPAs) are characterized by high intensity levels and can thus be more beneficial for health than other types of physical activity (1). However, studies suggest that OPAs decline from childhood to adolescence and determinants of OPA change are widely unknown (2). Therefore, this study aims at investigating changes in OPA participation during the transition from childhood to adolescence and the role of factors influencing OPA change. Methods This nationwide cohort study uses data from the cluster-randomized German Health Interview and Examination Survey for Children and Adolescents (KiGGS). Participants aged 6 to 10 years at KiGGS baseline (2003-2006) and 12 to 16 years at KiGGS Wave 1 (2009-2012) were included ($n = 3790$) in the study sample. The KiGGS response rate for the above mentioned age group was 70% and the KiGGS Wave 1 re-participation rate 74%. Weighted prevalence proportions were calculated for the OPA participation categories maintenance (reference), dropout, commencement, and abstinence. Multinomial logistic regression analysis was used to analyze the role of sex, age, socioeconomic status (SES), migrant background, family form, health status, motor fitness, media use, and residential area as influencing factors of OPA participation between KiGGS baseline and KiGGS Wave 1. Results The weighted prevalence was 48.5% (CI-95%: 46.2-50.8) for OPA maintenance, 12.3% (10.8-14.0) for commencement, 20.5% (18.7-22.4) for dropout and 18.7% (16.8-20.8) for abstinence. The predictor analysis indicates that being a girl and having a low motor fitness as well as having a low SES consistently predicted the abstinence, dropout and commencement of OPA participation. Conclusion To reduce the decline in OPA participation during childhood, especially girls and children from low SES families should be supported to participate in OPA or to maintain their OPA. The early promotion of motor fitness could be a promising approach. References 1. Marques A, Ekelund U, Sardinha LB. OP-SH20 Sport Consumers, Events & Tourism

HOW INTERNATIONAL SPORT EVENTS SUPPORT URBAN DEVELOPMENT? EFFECTS OF EYOF 2017 AND POSSIBILITIES OF GYŐR

MATE, T., ANDRAS, K.

Széchenyi István University and Corvinus University of Budapest

In the summer of 2017, for the first time it will be held in Hungary an international sports event represent several sports, which belongs to the Olympic events. The presentation is addressed to answer the question, how international sport events support urban development. Can be increase sport economic activity in City of Győr thanks to the effects of the EYOF? How new sport facilities can be operated sustainable and optimised economically? The main appearance of sports economics today are the international sport events. The central product of professional sport is variety of sports and sport events [András, 2011]. Important international sport events (e.g. Olympic Games, World Cups) from sports economics point of view has impacts to all the sport markets (consumer market, players market, market for broadcasting rights, sports sponsorship market, merchandising market). [András, 2003]. These international sport events have specific impacts not only on their own markets, but also on the host country / city's economy. Furthermore, in many cases can be discover such impacts that are not primarily economic, but are closely related to the economy. EYOF is an incentive factor in urban development, open up new opportunities for the City of Győr as a catalyst of investments. World-class sports facilities will be built and with the construction of the Olympic Centre neighborhood rehabilitation will be established. The purpose is sustainability, long-term and 100% utilization of facilities and optimization of operation. The biggest heritage of international sport event is facility development. In our study we present the experiences of utilization and facility management of sport facilities, based on our research carried out with online questionnaire. The research collects experiences of utilization and facility management of sport facilities from 8 cities of 7 countries (Central-Eastern Europe, Visegradi 4 Countries, neighbouring countries of Hungary extended to twin cities of Győr). We give the answer to the questions as follows: who is the operator and owner of sport facilities, level of capacity utilization of sport facilities, what is the primary function of sport facilities, how the users are paying for the usage of sport facilities? There is special attention dedicated to the topic from the fact that Hungary is competing to organize the Olympics Games in 2024. The application is based on the country's outstanding sport successes and the

experiences collected during several international sport events organized and held successfully in recent years. We can say that Hungary is world-class in organization of international sports events. The study aims to show how international sport events become developing power of the host country/cities. References: Krisztina András [2011]: 'The operating model of professional football. THE LEGACY OF THE FIFA WORLD CUP 2014 FACILITIES: WHITE ELEPHANTS OR FACILITIES FOR ENTERTAINMENT AND SPORTS?

ROCCO JR, A., MAZZEI, L.

School of Physical Education and Sport - USP

Introduction Brazil built and/or remodeled 12 football stadiums to host the FIFA World Cup (WC) 2014. The total invested in these arenas was around 1.956 trillion Euro. One and a half year after from the WC, the press reported that 8 of these 12 stadiums have losses in their operations. The aim of this paper is to evaluate the perspective of legacy for the 12 facilities built for the WC. Methods To achieve the aim, a questionnaire to evaluate the fans-consumers perception were applied in three different moments during 2014: a) before the WC in the "old" Brazilian stadiums; b) during the WC, in the stadiums used in the event; and, c) third, in the stadiums WC facilities, but during the local competitions, managed by Brazilian football organizations. The SPSS was used for descriptive analyses to identify the differences among the three moments. Content Analysis in news published by the press were also used to evaluate the legacy perspective of the WC facilities. Results A total sample of 11,052 people were answered the questionnaire in of the three moments. The main results were: in the first/third moments do not matter the quality of services offered of the facilities and event, but emotional aspects (related to football clubs) that make fans-consumers went to the stadiums. The entertainment was the main issue identified fans-consumers perception during the WC. It was identified high satisfaction rates and 93.19% said they would like to return to the facilities stadium, which can explained by the experienced lived during the second moment. Discussion Paramio et al. (2008) draw attention to the fact that the post-modern stadiums, arising from 1990, were born to be more functional and improve their design, the safety, accessibility and comfort for the spectators and especially the possibilities of economic exploitation of the facilities, including the promotion of others activities than football. All of the results clearly suggest that the new sports facilities and the quality of services collaborate to further football "entertainment" in the worldwide context. It is the "McDonaldization of society" (Ritzer, 2010). Although the public enjoyed the experience of the WC stadiums, in four cities these spaces are not feasible, in another four the combination sport x entertainment x world-class cities needs to be extremely efficient and only with efficient management can enable a sustainable operation in the Brazilian football facilities. The political choices of the host cities before the WC did not allow to Brazil to get the coherence that should exist between world-class cities, world-class stadiums and world-class events. References Paramio, J.L.; Buraimo, B.; Campos. C. (2008). From Modern to Postmodern: the development of football stadia in Europe. September 2008. Ritzer. G. (2010). The McDonaldization of Society. RESEARCH ON THE STRUCTURAL COMPONENTS AND FUNCTION ROUTE OF THE TECHNOLOGICAL INNOVATION OF SPORTING GOODS MANUFACTURER

LEI, Z., JIANRONG, Q., QINGHUI, L., DONG, Z., HE, D.

China Institute of Sport Science

Companies achieve competitive advantage through acts of innovation. Used literature research, interview method, questionnaire method, interpretative structural modeling, structural equation model to analyse the structural components and function route of the technological innovation of sporting goods manufacturer. It was found that the technological innovation of sporting goods manufacturer is a systemic behavior, a result of many factors' combined action. These components include research and development department, production department, sales department, universities, research institutes, intermediaries, governments, upstream firms, financial institutions, consumers, trades, sports event organizations, athletes, associations, original equipment manufacturers, medias, dealers and other firms. The structural modeling of components is a three-level hierarchical structure, the Level II contains research and development unit, manufacture unit and commercialization unit, some components of Level III have multifunction. The components increase the technological innovation output performance through promoting the running effect of research and development unit, manufacture unit and commercialization unit.

PS-PL02 Promoting physical activity – environmental and economic health approaches

URBAN ENVIRONMENTS - KEY DETERMINANT IN PROMOTING ACTIVE LIVING

BULL, F.

The University of Western Australia

Promoting physical activity is a global priority. In 2013 a global target for all countries was agreed, namely to increase population level of physical activity by 10% by 2025. How will we achieve this goal? A key determinant of participation is the urban environment, it can enable or hinder the opportunities to be active. Research from Australia and elsewhere provides clear evidence on the key features of a supportive 'healthy and active' environment. These include safe accessible infrastructure for walking and cycling, adequate open spaces and sporting facilities, quality public transport and appropriate diversity of destinations within walking and cycling distances. Findings from research will be presented to showcase how we can design cities and communities to be active spaces for people of all ages and tools to use in sharing this evidence. Our greatest challenge is achieving large scale implementation of what we know and effectively

engaging sectors outside of health and sports, such as transport and planning. Working in partnerships is necessary to ensure evidence is used to inform policy and create programs so we can achieve active healthy communities for future generations.

THE WHO HEALTH ECONOMIC ASSESSMENT TOOL – IN WHAT WAY CAN IT SUPPORT PHYSICAL ACTIVITY AND SUSTAINABILITY?

RACIOPPI, F., RUTTER, H.2, CAVILL, N.3, KAHLMEIER, S.4, SCHWEIZER, C.1, FOSTER, C.5, GOETSCHI, T.4, KELLY, P.6, OJA, P.7, WOODCOCK, J.8, SOMMER, H.8, DINSDALE, H.9

1. World Health Organization (WHO) Regional Office for Europe, Copenhagen, DK, 2. London School of Hygiene and Tropical Medicine, UK, 3. Cavill Associates, UK, 4. Uni of Zurich, Switzerland, 5. Oxford

Introduction With nearly one million deaths per year attributable to physical inactivity in the 53 countries of the WHO European Region, this risk factor has become a leading public health priority. Regular cycling and walking are highly effective in reducing the risk of premature mortality and morbidity from the broad range of non-communicable diseases related to physical inactivity. If accompanied by a modal shift that reduces motorized transport levels, cycling and walking can provide additional co-benefits by reducing emissions of air pollutants, greenhouse gases and noise, alleviating congestion, improving road safety, and contributing to a better quality of urban life. Since promoting cycling and walking depends on policy decisions taken mostly by local authorities in charge of urban transport and land use planning, there is a need to support them in appreciating the magnitude of the benefits that could be delivered by cycling and walking, including in economic terms. **Methods** The WHO Health Economic Assessment Tools (HEAT) for walking and cycling (WHO, 2014) were developed to estimate the economic value of reduced premature mortality that results from regular walking or cycling. HEAT are available online, based on best available evidence, and open to further developments as new knowledge becomes available. They are specifically designed to meet the needs of an audience that may have limited access to the extensive set of inputs that would be required by complex assessment models in terms of epidemiological, transport-related and economic data, and/or limited experience of how to perform these assessments. At the same time, the HEAT allow for more advanced implementations, if data and expertise are available. **Results** Since 2007, nearly 100 applications of the HEAT have been documented applied globally by cities, national governments, researchers, practitioners and active mobility advocates, including 14 government or policy guidance documents and 28 academic papers. **Discussion** In the context of the 2030 Sustainable Development Agenda, cycling and walking can contribute to the achievement of sustainable development goals related not only to health, but also to "making cities and human settlements inclusive, safe, resilient and sustainable". The HEAT support the key actors for the promotion of cycling and walking in this endeavour.

KINEMATIC STEP-PARAMETERS AND TRIPLE JUMP PERFORMANCE IN FEMALE YOUTH ATHLETES

JAITNER, T., VAN HAREN, A., HAHN, D.

TU Dortmund University; RUB Bochum University

INTRODUCTION Especially in youth athletes, the step in triple jumping is considered to be crucial since it rather serves as a transition phase between hop and jump than as a major contributor to the overall distance (Hay, 1993). This is further supported by observations that during the step youth athletes do not perform a jump but a running step, which is in accordance with the suggestion of Hay and Miller (1985) that a more accentuated step results in a greater overall distance. Therefore, the aim of this study was to investigate the relationship between kinematic step-parameters and step-distance as well as their contribution to the overall performance. **METHODS** Distances and contact times of hop, step and jump as well as flight times of hop and step were recorded from 129 jumps of 32 female youth triple jumpers using Optojump next™ (Microgate, Italy) during regional and national championships. Mean approach velocity (v_a) was determined between 6m and 1m before take-off. Actual overall distance, phase distances and phase ratios (% of overall distance) were determined according to Hay (1993). Step flight ratio and the change in horizontal velocity from hop to step (Δv) were also calculated. Several correlation coefficients between the kinematic parameters obtained were determined according to Pearson and Spearman depending on normal distribution. **RESULTS** Mean and SD for v_a , overall and phase distances reached $7.7 \pm .5$ m/s, $10.69 \pm .63$ m, $3.89 \pm .31$ m (hop), $2.62 \pm .48$ m (step), and $4.18 \pm .39$ m (jump), respectively. Mean phase ratios were $36 \pm 2\%$ (hop), $24 \pm 4\%$ (step), $39 \pm 4\%$ (jump). Step flight ratio achieved $49 \pm 13\%$, while Δv was -1.5 ± 3.8 m/s. Overall distance showed moderate correlations to v_a ($r = .443$) and step-distance ($r = .548$) but a strong correlation to hop-distance ($r = .841$). Further did step-distance inversely influence jump-distance ($r = -.61$). Step-parameters phase ratio, Δv , flight ratio were highly to moderately related to step distance ($r = .944, -.565, .684$) but could not predict overall triple jump performance ($r \le .4$). **DISCUSSION** According to our results, hop distance had the greatest influence on triple jump performance. However, also the step significantly affected overall distance, and kinematic step parameters revealed that a good step is mainly characterized by a high phase ratio but also by a reduction in velocity from hop to step and a high flight ratio. This points towards a jump-accentuated step rather than representing a running step used as transition phase from hop to jump. In future, multi-regression analysis is needed to explain the more complex interaction of the parameters that contribute to greater performances. **REFERENCES** Hay, J.G. (1993). *J. Biomech.*, 26, Suppl. 1, 7-21. Hay, J.G. & Miller, J.A. (1985). *IJSB*, 1, 185-196.

EFFECTS OF MUSCLE FORCES ON HORIZONTAL AND VERTICAL VELOCITIES OF THE BODY MASS CENTER DURING FORWARD AND VERTICAL JUMPING

SUZUKI, Y.1, KOBAYASHI, Y.2, TAKIZAWA, M.2, MURATA, M.3

1: OCU (Osaka, Japan), 2: IPUHS (Ami, Japan), 3: JISS (Tokyo, Japan)

Introduction To jump higher or farther, an athlete needs to produce greater velocity of the center of body mass until take-off. Because most of this velocity is produced by the muscles of the lower limbs, information about how these individual muscles accelerate the body mass center is useful to understanding the mechanism of jump motions. The purpose of this study was to estimate the effects of muscle forces on the horizontal and vertical velocities of the body mass center during forward and vertical jumps. Methods Vertical (VJ) and forward squat jumps (FJ) were simulated using a forward dynamic model of the musculoskeletal system, and induced acceleration analysis was performed to quantify the velocity of the mass center produced by each muscle force. The musculoskeletal system used in this study consisted of four rigid segments (head-arms-trunk, thighs, shanks, and feet) connected with hinge joints. In this model, six muscle-tendon complexes (gluteus maximus, rectus femoris, vasti, hamstrings, gastrocnemius, and soleus) were implemented. A Hill-type muscle model consisting of a contractile element, a series elastic element, and a parallel elastic element was used to represent each of these six muscle-tendon complexes. Activation dynamics of the muscles were modeled based on Bobbert & van Zandwijk (1999). Stimulation of each muscle was increased toward its maximum of 1.0, then decreased toward its minimum of 0. The object functions for motion optimization were set as height and horizontal distance of the mass center for VJ and FJ, respectively. The stimulation onset and offset times of each muscle were optimized using a genetic algorithm. Results & Discussion The horizontal and vertical velocities of the mass center at the instant of take-off were 0.05 m/s and 2.65 m/s for VJ and 0.93 m/s and 2.28 m/s for FJ. In both VJ and FJ, most vertical velocity was produced by the soleus and gastrocnemius. During VJ and FJ, the hamstrings, soleus, and gastrocnemius accelerated the mass center forward, while the rectus femoris and vasti accelerated backward. A marked difference was observed in the forward velocity produced by the hamstrings (VJ, 0.80 m/s; FJ, 1.45 m/s). This difference between VJ and FJ appeared to be because the hamstrings were the main contributor to forward acceleration, but also slightly accelerated the mass center downward. These results suggest that the hamstrings play an important role in increasing forward velocity and adapting the direction of the mass center's velocity during jumping. THE EFFECT OF ANKLE TAPING ON ANKLE DYNAMICS DURING LANDINGS ON AN INCLINED SURFACE

SATO, N., NUNOME, H., HOPPER, L., IKEGAMI, Y.

Nagoya Gakuin University

Introduction Ankle taping is commonly used to reduce the incidence of ankle sprains (Verhagen et al., 2000). There are no consistent results regarding the efficacy of taping on modifying ankle joint dynamics. The purpose of this study was to determine the effect of ankle taping on ankle joint kinematics and kinetics by analyzing external moment derived from two component of ground reaction force (GRF) during drop landings on an inclined surface. Methods Twenty-five healthy adults participated in this study. The participants landed on a force platform which was inclined at 25 degrees from a height of 0.3 m. Their landing movement were captured using a eight-camera motion capture system. Stirrups and figure eight taping techniques were used. After the taping trials, the taping straps were disconnected and the participants were repeated exact same landing trials in this condition as control trials. Dependent variables included the average magnitude of the external inversion ankle moment of force from initial foot contact to the end of the first peak of GRF, the effective lever arm length to medio-lateral and vertical GRF components, and the ankle inversion angle at the peak ankle inversion moment were calculated and compared between the two trials. Results In the taping trials, the average inversion moment was significantly smaller ($p < 0.01$) than that of the control trials. There was no significant difference in the effective lever arm length to the vertical GRF component. However, medio-lateral GRF at the peak ankle inversion moment, was significantly smaller ($p < 0.05$) in the taping trials. The resultant ankle inversion angle at the peak ankle inversion moment was also significantly smaller ($p < 0.05$) in the taping trials. Discussion Ankle taping could work to prevent ankle joint inversion during landing, due to smaller ankle inversion moments and joint angles under taped conditions. If ankle taping alters the foot orientation relative to the ground and shortens the effective lever arm to medio-lateral GRF during landing, this may subsequently reduce the external inverting moment of force at the ankle. Foot Pressure Analysis of The Grab, Track and Kick Start Techniques in Swimming Introduction: The goal of swimming race is to complete the required distance in the least amount of time. Swimmers start performance is vital to win the race. The purpose of the current study was to investigate plantar pressure values and start performance parameters for grab, track, and kick-start techniques from the Omega OSB11 starting block. Method: Nineteen male from the Turkish national swimming team (age 16.84 ± 1.68 years, height 179.9 ± 5.8 cm, body mass 57.9 ± 7.1 kg) volunteered to participate in this study. The swimmers were instructed to perform three different start techniques (grab, tract and kick start) and finish the start performance at 15-m distance. The participants completed a warm up similar to their pre-race routine and they performed two trials for each start technique. Trials were recorded with two digital video cameras. Start efficiency times were recorded by a touchpad positioned at 15 m distance from starting block and electronic time system (Omega, ARES21, Switzerland) for grab-start, track-start and kick-start techniques. Foot plantar pressure data were collected using an F-Scan VersaTek wireless system (Tekscan, Inc. South Boston, MA) during three different start techniques. Prior to data collection F-scan sensors (model: 3000E; resolution: 3.9 sensors/cm²) were calibrated and data was taken with the 100 Hz sampling rate. Peak and average pressure data were analyzed by using the F-Scan Mobile Research software. Results: Statistical comparisons were made among plantar pressure values of three different start techniques and also 15 m swimming performance using one-way ANNOVA. The average and peak foot pressure values (N/cm²) were significantly lower for kick-start position (mean: 12.68 ± 2.3 ; peak: 16.45 ± 3.4) than both tract (mean: 16.58 ± 3.4 ; peak: 21.0 ± 3.7) and grab-start (mean: 19.42 ± 2.8 ; peak: 23.58 ± 4) positions ($p=0.00$) during push of phase in the front leg. Similarly, the average and peak foot pressure values were significantly less for kick-start position than both tract and grab-start positions ($p=0.00$) during push of phase in the rear leg. Although, there were no significant differences in time to 15m, distance of entrance among swimming start techniques, kick start technique was faster and also resulted in longer distance of entry than the other start techniques ($p>0.05$). Discussion: At kick start technique, although the foot pressure was lower than the other start techniques during push off phase, distance of entry was

longer and the time of the 15 m swimming is shorter. However, this study results are conflicting with another study. Slowson SE et al. (2013) stated that swimmers generating higher than average peak forces were more likely to produce a better overall start performance. In our study, low levels of average peak pressure resulted in better start performance. Future works should be applied to explain relationship between foot pressure, block time, distance of entry and muscle strength. Suzun17@yahoo.com

REDUCED ACTIVATION IN ISOMETRIC MUSCLE ACTION AFTER LENGTHENING CONTRACTIONS IS NOT ACCOMPANIED BY REDUCED PERIPHERAL FATIGUE

SEIBERL, W.1, PATERNOSTER, F.K.1, HAHN, D.2, SCHWIRTZ, A.1

1) Technical University of Munich, 2) Ruhr-University Bochum

Introduction: When an active muscle is stretched the resulting post-eccentric steady-state force is greater than an isometric force at corresponding muscle length and activation. Further, for a given force less muscle activation is required after active stretch. The characteristics of this activation reduction (AR) within so-called residual force enhancement (RFE) were associated with reduced metabolic costs [1, 2]. This study focused on long lasting effects of RFE mechanisms and aimed to identify if stretch-induced AR persists over sustained contractions resulting in a positive influence on the development of peripheral and/or central fatigue. **Methods:** Knee extension torque of n=16 subjects was measured and EMG data of mm. vastus lateralis, rectus femoris, vastus medialis were recorded (4kHz). A 60s fatiguing isometric muscle action was performed at an intensity level of 60% of maximum voluntary contraction (MVC). After 4h rest, a second 60s fatiguing isometric contraction was performed that was preceded by an active stretch (20°; 60°·s⁻¹). Each fatiguing task was preceded and followed by MVCs. The interpolated twitch technique was used to analyze voluntary activation (VA) and peripheral fatigue. Baseline parameters contained MVC torques, VA and the resting twitches (RT). For endurance trials force and EMG data were analyzed over 5 time windows every 10s. Repeated measures ANOVA served for statistics. **Results:** We found no significant differences of baseline values before endurance tasks but significant AR after stretch contractions (~90% of isometric EMG). After fatiguing trials MVC torque and RTs were significantly reduced (~70% of baseline) but there were no differences between contraction conditions. **Conclusion:** Results of AR are in accordance with previous work [2]. Although there was reduced activation for maintaining a given amount of force, preceding stretch did not reduce influence of peripheral fatigue, measured immediately after fatiguing trials. It is known that mechanisms associated with RFE operate as long as the muscle is kept active. It may be speculated that reduced activation was possible due to passive structural connections, such as titin, that support maintenance of muscle force. However, these mechanisms do not persist after deactivation and therefore may not have influenced fatigue tests. **References:** 1. Joumaa, V. and W. Herzog, Energy cost of force production is reduced after active stretch in skinned muscle fibres. *Journal of biomechanics*, 2013. 46(6): p. 1135-1139. wolfgang.seiberl@tum.de

OXYGEN CONSUMPTION OF GASTROCNEMIUS MEDIALIS MUSCLE DURING SUBMAXIMAL VOLUNTARY ISOMETRIC CONTRACTIONS WITH AND WITHOUT PRECEDING STRETCH

PATERNOSTER, F.K.1, SEIBERL, W.1, SCHWIRTZ, A.1, HAHN, D.2

1 Technical University of Munich 2 Ruhr-University of Bochum

Introduction Activation reduction (AR) within the context of residual force enhancement stands for a lower muscle activity in the isometric steady state after an active stretch compared to a purely isometric contraction at the same muscle length and a given force. AR is associated with a potential reduction of metabolic cost during the contraction and Joumaa and Herzog (2013) showed energetic advantages during force production after active stretch for skinned muscle fibers. However, to date it is unclear if these results can be transferred to in vivo human muscle function. Therefore, the aim of this study was to measure oxygen consumption during isometric contractions of gastrocnemius medialis (GM) with and without the presence of AR. **Method** Subjects (n=7) performed submaximal voluntary isometric plantar flexions (30% MVC, 60s) at 15° dorsi flexion with and without a preceding 30° amplitude stretch (w=60°/s.). Ankle joint torque during contractions was measured using an isokinetic dynamometer and muscle activity of the triceps surae was obtained by EMG. A near infrared spectroscopy system (NIRS) was used to quantify oxygen consumption of GM. To exclude blood volume changes throughout the contractions an external pressure cuff was used to fully occlude the lower leg. Results Sustained torque and ankle angle data revealed no differences between contraction conditions during the isometric steady state ($p > 0.05$). There was a significant overall AR up to $7.8\% \pm 5.2\%$ for the summed triceps EMG, and $20.5\% \pm 11.7\%$ for explicitly measured GM after active stretch compared to the pure isometric contraction. Oxygen consumption of GM showed no statistical difference ($p = 0.082$), despite a decrease of $6.2\% \pm 6\%$ regarding the mean slopes of the oxygenated and deoxygenated hemoglobin after active stretch, as a representative of oxygen consumption per unit of time. **Discussion** The observed AR is in accordance to previous published results (Seiberl et al. 2012). However, reduced activation did not lead to energetic benefits in terms of oxygen consumption. These results were not expected as hypotheses were based on previous work of Joumaa and Herzog (2013). This may be due to used methods. The NIRS system only reflects small parts of the GM muscle and therefore only provides an incomplete reflection of the energy consumption of the whole triceps group. This may explain the differences regarding beneficial energetic effects of AR and muscle oxygenation. **References** Joumaa V. and Herzog W. (2013). *J. Biomech* 46, 1135-1139 Seiberl W. et al. ASSOCIATIONS OF SLEEP DURATION, BODY COMPOSITION AND AEROBIC FITNESS IN YOUTH

OLAFSDOTTIR, A.S., HERMODSDOTTIR, H.E.R., KJARTANSODOTTIR, I.K.

University of Iceland, School of Education

Adolescence is the second most rapid period of body growth and development after infancy and therefore they need a lot of sleep. However, it can often be difficult for adolescents to obtain enough sleep because they tend to go to bed late and wake up early, due to

changes in biological clock and lifestyle. Short sleep duration has been associated with higher body mass index (BMI), higher body fat percentage and increased risk of obesity in studies, especially in children and adults. However, less is known about this relationship between sleep duration and body composition in adolescents. Therefore, the aim was to examine the relationship between sleep duration and body composition in Icelandic youth as well as the relationship between sleep duration and the feeling of getting enough sleep. This was a cross-sectional study of 262 (55% girls) Icelandic youth, aged 17.5 to 19.0 years. Body composition was assessed with measurements of height, weight, BMI, waist circumference (WC), waist to height ratio (WHR), and body fat percentage. Sleep duration and the feeling of getting enough sleep were assessed by questionnaire, and average sleep duration score was calculated from the ratio between sleep on weekdays and weekends. Aerobic fitness was estimated by a graded exercise test on a cycle ergometer. Hierarchical multiple linear regression was performed to evaluate the relationship between body composition variables and sleep duration, after controlling for peak oxygen uptake (VO_{2peak}) and leisure time behavior. The primary findings of this study were that sleep duration during weekdays, when adjusted for VO_{2peak} and leisure time behavior, was negatively associated with body composition in boys only, but sleep was only associated with body composition in girls in the unadjusted model. Of all body composition measures WC had the strongest association with sleep duration. Both boys and girls who thought they did not get enough sleep were more often classified as sleeping six hours or less compared to those who felt they slept enough. In addition, those sleeping six hours or less also had more unfavorable body composition measurements compared to those who slept longer, indicating that six hours or less sleep may not be enough for this age group. This study indicates that sleep has small but important association with body composition and the association between shorter sleep duration and body composition is complex, and it may vary between the sexes in late adolescence.

REDUCED HBA1C AFTER 12 WEEKS OF HIGH-INTENSIVE AEROBIC INTERVAL TRAINING AMONG TYPE 2 DIABETICS.

STØA, E.M., MELING, S., NYHUS, L.K., STRØMSTAD, G., MANGERUD, K.M., HELGERUD, J., BRATLAND-SANDA, S., STØREN, Ø.
University College of Southeast Norway

Background: The effectiveness of high-intensity aerobic interval training (HAIT) to reduce risk factors associated with type 2 diabetes (T2D) remains to be established. This study investigated the effects of HAIT on maximal oxygen uptake (VO_{2max}), glycated Hemoglobin type A1C (HbA1c), fat oxidation rate (FatOx), work economy (WE), body weight (BW) percent body fat (%BF), energy expenditure (EE) during exercise, lactate threshold (LT) blood pressure (BP) and blood lipid profile (triglycerides, HDL, LDL, total cholesterol) among individuals with type 2 diabetes. **Methods:** 19 sedentary men and women diagnosed with T2D completed 12 weeks of supervised high-intensity outdoor training three times per week. The interval training program consisted of 4 x 4 minutes at an intensity between 85-95% Hfpeak. **Results:** After the HAIT intervention, VO_{2max} was increased by 21% (from 25.6 ml·kg⁻¹·min⁻¹ to 30.9 ml·kg⁻¹·min⁻¹, p <0.01), and HbA1c reduced by 8% (from 7.78% to 7.2%, p <0.01). Reductions were also found in BW (p <0.01), %BF (p <0.01), waist circumference (p <0.01), hip circumference (p <0.01), diastolic BP (p <0.01). Velocity at LT (p <0.01) was also increased. There was a tendency towards an improved FatOx at 60% VO_{2max} (from 0.368 to 0.420 g·min⁻¹, p = 0.065). No changes were found in WE or blood lipid profile. **Conclusion:** The results from this study showed that HAIT was an effective exercise strategy to improve aerobic fitness and reduce risk factors associated with type 2 diabetes.

REPEATED SPRINT EXERCISE TRAINING IN NORMOBARIC HYPOXIA IMPROVES CARDIO-METABOLIC FUNCTION IN OBESE YOUNG WOMEN

KONG, Z., SONG, L., SHI, Q., NIE, J.
University of Macau

Background No studies investigates whether low-volume HIE in hypoxia including repeated sprinting exercise (RSE) has an extra effect on body composition and metabolic risk factors. **METHODS** A single-blind randomized controlled experimental design was used to conduct a 5-week repeated-sprint exercise intervention in hypoxia or normoxia. 24 obese young women completed all 20 sessions either in hypoxic (RS_H, N=11) or normoxic high-intensity interval exercise training (RS_N, N=13). The RSE protocol comprised 8 s of sprinting and 12 s of rest for a maximum of 60 repetitions for 20 min. Body composition measured by DEXA and blood samples were assessed at pre- and post-intervention in the follicular or luteal phase of menstrual cycle. Physical activity and food diary were estimated during the study. **RESULTS** There were no within- and between-group differences in daily energy intake and physical activity at pre-, during-, and post-intervention times (p > 0.05). Five weeks of RSE resulted in significantly improvements in absolute and relative VO_{2peak} and maximal O₂ pulse in both groups (p<0.01). The increments of VO_{2peak} and maximal O₂ pulse in RS_H (~20%) were twice as much as in RS_N (~10%) (p<0.05, d = 0.88-0.95). There were no significant improvements in weight, BMI, total or regional body composition, TC, HDL-C, LDL-C, and leptin after hypoxic or normoxic training and no differences between groups. There was a trend to decrease in TG in RS_H (p=0.051) and the decrement tended to be significant than RS_N training, either (RS_N -22.8±36.0%, RS_H 6.8±31.7%, p = 0.054, d = 0.87). For the subjects in RS_H, the changes in VO_{2peak} were moderately related to the changes in total FM ($r = -0.64$, $p < 0.05$), leg FM ($r = -0.74$, $p < 0.01$) and Trunk FM ($r = -0.50$, $p = 0.121$), while significant correlations were found between the changes of maximal O₂ pulse and the changes of total FM ($r = -0.70$, $p < 0.05$), leg FM ($r = -0.64$, $p < 0.05$), and Trunk FM ($r = -0.64$, $p < 0.05$). In contrast, low and no significant correlations ($r = -0.03$ to -0.25) between VO_{2peak}/maximal O₂ pulse and total and regional fat mass in the subjects of RS_N. Changes of blood lipids and serum leptin didn't correlate with the changes of cardiovascular fitness and body composition (p > 0.05). **DISCUSSION** 20 sessions in five weeks of hypoxic and normoxic repeated-sprint exercise training improved cardiorespiratory fitness but had no effect on body composition, TC, HDL-C, LDL-C and circulating leptin levels in sedentary obese young women, whereas hypoxic RS training had larger enhancements in VO_{2peak}, maximal peak O₂ pulse and TG than normoxic RS did. We did not observe significant improvements in RS_H and RS_N group as well as an additive effect on body composition caused by RS_H. The changes of VO_{2peak} and maximal peak O₂ pulse were negatively associated with the changes of total and regional fat mass in RS_H but not in RS_N, suggesting that hypoxia seems to play a crucial role in improving body composition.

EFFECTS OF CONCURRENT STRENGTH AND ENDURANCE TRAINING ON PHYSICAL PERFORMANCE IN PATIENTS WITH PARKINSON'S DISEASE

VAJDA, M.1, TIRPÁKOVÁ, V.3, SLOBODOVÁ, L.2,4, CVEČKA, J.1, VALKOVIČ, P.4, VANDERKA, M.1, KRÁLIK, M.1, UKROPEC, J.2, UKROPCOVÁ, B.2,4, SEDLIAK, M.1

Comenius University

1: Faculty of Physical Education and Sports Comenius University; 2: Institute of Experimental Endocrinology, BMC, SAS; 3: Slovak Medical University; 4: Faculty of Medicine, CU, Bratislava, Slovakia
Introduction Parkinson's disease (PD) is a neurodegenerative disease characterized, among others by postural instability, rigidity, tremor and hypokinesia. Structured physical activity programs have been shown to have a positive effect on muscle strength, endurance and functional tasks/performance in PD patients (Combs et al., 2013; Paul et al., 2014). The combination of endurance and resistance exercise may result in synergy training effect (Shulman et al., 2013). This study aimed to identify the effects of concurrent supervised strength and endurance training on physical performance in PD patients. **Methods** Two groups volunteered in this study: PD group (6/2, F/M, 64±7.43 years) and Control group (8/3, F/M, 68±8.38 years). The 12-week training consisted of two concurrent strength-endurance sessions and one endurance-coordination session/week. Both groups performed the same program. Physical performance was measured before and after intervention: 1RM (leg-press), maximal isometric knee extension and flexion, Rockport Walk Test, 10 Meter Timed Fast (10mF) and Comfortable (10mC) Speed Walking tests, Five Times Sit and Stand Test and static postural stability in a different mode (open eyes, closed eyes and semi-tandem). The repeated ANOVA was used for main effect of training and the Mann-Whitney U-test for between group comparisons. Results In both groups, physical performance was improved in 1RM ($p<0.05$), Rockport Walk Test ($p<0.001$), 10mC ($p<0.001$) and Five Times Tit and Stand Test ($p<0.05$) following 12-weeks training. No significant differences were recorded in other tests. No significant between-group differences were reported in any measured parameters. **Discussion** The 12-week concurrent strength-endurance training was effective in improving physical performance in PD patients. The improvements were comparable to healthy controls. We suggest that supervised physical intervention combining strength, endurance and coordination may be an effective supportive strategy in treatment of Parkinson's disease. RELATIONSHIP OF PHYSICAL FITNESS, VITALITY, AND COGNITIVE FUNCTION WITH PHYSICAL ACTIVITY PATTERNS IN INSTITUTIONALIZED ELDERLY INDIVIDUALS

KAMIYA, M., IKEZOE, T., MASAKI, M., ARAKI, K., KATO, T., INOUE, W., ISONO, R., KOYAMA, Y., NAKAO, S., ICHIHASHI, N.

Kyoto University

Introduction It has been reported that daytime physical activity patterns, such as walking and sitting time, are associated with physical fitness in institutionalized elderly individuals (Ikezoe et al., 2013). However, the effect of vitality and cognitive function on physical activity patterns remains unclear. The aim of this study was to examine the relationship of physical fitness, vitality, and cognitive function with physical activity patterns in institutionalized elderly individuals. **Methods** The subjects comprised 27 elderly individuals (8 men and 19 women, mean age 83.2 years) who resided in a nursing home. The subjects were able to ambulate independently and did not have an unstable physical condition or severe dementia. Physical activity patterns, such as walking, standing, sitting, and lying total time in 24 hours, were assessed using the two tri-axial accelerometers (A-MES; Solid Brains Inc.). The number of steps taken in 24-hours was also measured. Physical activity data were collected for two days. Activities of daily living-related vitality and cognitive function were assessed by vitality index (VI) and Mini-Mental State Examination (MMSE), respectively. Physical fitness measures included muscle strength (hip extension, knee extension, and plantar flexor), balance (one-legged standing time and TUG), muscle power (five-time chair stand), agility (stepping test) and muscle endurance (30-s chair stand). Stepwise regression analysis was performed with physical activities as dependent variables and VI, MMSE, and physical fitness as independent variables. **Results** Mean total times in 24-hours were as follows: walking 159.7 ± 72.8 min (11.1%), standing 83.1 ± 58.3 min (5.8%), sitting 455.8 ± 137.7 min (31.7%), and lying 741.4 ± 177.4 min (51.5%). The number of steps was 3945.8 ± 3307.8 . Stepwise regression analyses identified plantar flexor strength for walking time ($\beta = 0.425$) and stepping test for the number of steps ($\beta = 0.583$). No factor affected the standing, sitting, and lying times. **Discussion** This study showed that plantar flexor strength and agility were independent determinants of time spent on walking and number of steps, which suggests that ambulatory activity in institutionalized elderly individuals may be more related to physical fitness than vitality and cognitive function. On the other hand, our findings showed no associations of physical fitness, vitality, and cognitive function with total times of standing, sitting, and lying. EFFECTIVENESS OF SUPERVISED EXERCISE PROGRAM FOR CARDIAC PATIENTS IN A "PLAESTRA SICURA" CERTIFIED FITNESS CENTER

FELISATTI, M., BRANDOLESE, I., POZZATO, E., TRENTINI, M., CHIARANDA, G., POMIDORI, L.

Esercizio Vita Center

INTRODUCTION Emilia-Romagna (Region of Italy) encourages a network of certificated gyms and fitness centers ("Palestra Sicura") for supervised exercise programs for people affected by chronic diseases, including cardiovascular diseases. Exercise is prescribed by the Sports Medicine Centers of the Public Healthcare System and supervised by II level degree exercise professionals in the "Palestra Sicura" gym. Aim of the study was to verify the additional benefit of a 1 yr supervised exercise program against a non-supervised exercise program. The supervised program was performed in the "Palestra Sicura" Esercizio Vita (Ferrara, Italy). **METHODS** Patients (age 70, 8 ± 3.4 yrs) were tested for clinical purpose at the local Sports Medicine Center with Bruce stress test for estimation of VO_{2peak} (Bruce; 1972) and with a percentually-regulated walking test performed on a treadmill (IKWT, Chiaranda et al; 2013). "Palestra Sicura" exercise professionals collected data of 7 consecutive cardiac patients (age 70.8 ± 3.4 yrs) through at a 3-steps test: at the beginning of a non-supervised exercise program (T0), at the time of referral to the palestra sicura (TR) and after 12 months of supervised exercise program (TC). A physical activity questionnaire has been delivered both at TC e TR (Ainsworth et al; 2011). Paired t-tests were performed to test significant differences among T0 and TR and TR and TC. **RESULTS** No patient dropped out before the end of the supervised exercise program. Physical activity level increased from 12.3 ± 6.1 mets/week to 24.3 ± 8.3 met week ($p < 0.005$). Walking speed at the IKWT test was 3.5 ± 0.8 at T0, 3.6 ± 0.7 at TR and significantly increased to 4.4 ± 1.1 at TC ($p < 0.01$). VO_{2peak} estimation by Bruce test METmax estimated by Bruce Stress Test

was 5.7 ± 1.2 at T0, 5.9 ± 0.9 at TR and significantly increased to 6.5 ± 1.4 at TC ($P < 0.01$), while no significant variation in HR max was observed. DISCUSSION A significant improvement in functional capacity and physical activity level was seen during the 12 months supervised program with respect to the previous non-supervised program. The observed improvement in walking speed of 0.8 km/h was associated to a 50% reduction of risks of death. The network of fitness centers with II level degree exercise specialist may increase the efficiency of exercise-based secondary prevention program. LOCATION ANALYSIS OF REHABILITATION SPORT PROGRAMS AND THEIR REACHABILITY - SERVICES FOR THE ELDERLY PUBLIC AND THEIR HEALTH CARE IN RURAL AREAS

BEHRENS, K.1, WEIPPERT, M.1, BEHRENS, M.1, PUDSCHUN, U.3, KLINGER, R.2

(1) Department of Sport Science, University of Rostock, Germany (2) Department of Sport Physiology and Health Science (Rostock), Germany (3) Landessportbund Mecklenburg-Vorpommern (Schwerin), Germany

Background: Emerging and progressing chronic diseases are known to be significantly enforced by physical inactivity. In regards to the negative development of kinetic behavior and its consequences, there has been a strenuous effort to increase sportive and physical activities among all age groups. Sport associations have therefore established a use of adequate instruments to effectively attend to the process of "healthy aging" and specifically release the health care system (§43 (1) SGB V i. V. m. §44 (1) SGB IX). In this context we investigated the care system coverage of ambulant rehabilitation sports (aRS) in Westmecklenburg/MV and their reachability. We prepared cartographic data on the reachability by car and by public transport (ÖPNV) at different times of day. **Result:** The ÖPNV reachability analysis clearly shows great difficulty to fairly reach the offered rehabilitation sport programs in this region. 47,7 % of the population need more than 60 min and 18,6 % need more than 90 min driving time to make use of a 45-minute offer in the morning hours. Using the offered programs in the evening hours is additionally difficult: 33,3 % of the Westmecklenburg population need more than two hours for the way back home. On the other hand, regional metropolises of Westmecklenburg and their immediate environs have an overall good reachability provided there are any sport offers to use. **Discussion:** The results underline the necessity to further extend aRS-offers. Both urban as well as rural areas lack a sufficient quantity of rehabilitation sport offers.

AEROBIC EXERCISE TRAINING CHANGES IN BRACHIAL ARTERY SHEAR PATTERNS IN MIDDLE AGED AND OLDER ADULTS

TANAHASHI, K., KOSAKI, K., SAWANO, Y., AKAZAWA, N., YOSHIKAWA, T., TAGAWA, K., MATSUBARA, T., MYOENZONO, K., TOCHIGI, Y., MAEDA, S.

University of Tsukuba

Introduction: Hemodynamic shear stress is the frictional force of blood on the arterial wall. Shear stress demonstrates a typical pattern (i.e., antegrade and retrograde shear). Elevation in antegrade shear stress is associated with anti-atherogenic effects on the endothelium. In contrast, elevation in retrograde shear stress may be potentially pro-atherogenic effects. Aging causes to decreased antegrade shear rate and increased retrograde shear rate in peripheral conduit arteries. The change in shear patterns with aging may participate in development and progression of atherosclerosis. Aerobic exercise training is an effective strategy to prevent atherosclerotic cardiovascular disease. However, the effect of aerobic exercise training on peripheral conduit arteries shear patterns in middle aged and older adults has not been investigated. The purpose of this study was to determine whether aerobic exercise training changes in brachial artery shear patterns in middle aged and older adults. **Methods:** Thirty-nine middle aged and older adults were divided into 2 groups: an exercise group ($n = 26$) and a control group ($n = 13$). Subjects in the exercise group completed 12 weeks of aerobic exercise training (65%–80% of maximal heart rate, 40–60 min/day, 3–6 days/week). Before and after each intervention, resting brachial artery shear rate was evaluated in all participants. **Results:** The baseline brachial antegrade shear rate, retrograde shear rate and most other key dependent variables did not differ between the 2 groups. In the exercise group, brachial antegrade shear rate significantly increased after exercise intervention ($P < 0.01$), and retrograde shear rate significantly decreased ($P < 0.05$). **Conclusion:** We found that aerobic exercise training changes in brachial artery shear patterns in middle aged and older adults. The result of this study suggests that the change in shear patterns by aerobic exercise training may have a beneficial effect in prevention of atherosclerotic disease.

EFFECTS OF EXERCISE ON ISOPROTERENOL-INDUCED CARDIAC DAMAGE IN RAT LINKED TO BRAIN FUNCTIONS

TÓTH, K., SCHOEAKER, R.G., VAN DER ZEE, E.A., NYAKAS, C.J.

University of Physical Education, Budapest, Hungary

Introduction A bidirectional relationship was found between myocardial infarction (MI) and depression in patients, furthermore comorbidity worsens prognosis. Alterations in neuroimmune processes are suspected to play a role in this link. Studies on rats also confirmed this phenomenon and opened new aspects in finding the exact underlying mechanisms in the brain immune system. In clinical practice currently no treatment is applied that targets both conditions at once, although exercise has already been shown to be beneficial for both conditions separately. Moreover, the accompanying depression in MI needs special and novel exercise treatment protocol. **Objectives** To investigate the future options in movement therapy, rats were used to study (1) whether isoproterenol-induced cardiac damage can mimic MI by leading to neuroinflammation, behavioral and cognitive changes; and (2) whether exercise can affect these parameters and improve health condition. **Methods** Female Wistar rats (11 months) were injected with either isoproterenol hydrochloride (ISO); a non-selective β -adrenoceptor agonist (in 70mg/kg dose) or saline s.c. on two consecutive days. Both groups were divided into sedentary and exercise subgroups undergoing 4 weeks of moderate intensity treadmill running. Cardiac function was assessed with echocardiography. Depressive-like behavior was measured by open field (OF) and sucrose preference tests, while cognition with novel location (NL) and novel object recognition tests. Neuroinflammation was estimated by microglia activation histologically. **Results** Cardiac dysfunction after ISO injection was confirmed by lower ejection fraction, which was slightly counterweighted by exercise. ISO enhanced hyper-ramification type of microglial activation in the hippocampus. Behaviorally ISO treatment had no influence on hedonic behavior of depression type, but exercise decreased anxiety in the OF. Regarding cognition ISO interfered with NL performance. Exercise appeared to counteract most of the ISO-induced effects in a variable extent. **Conclusions** Cardiac dysfunction after repeated ISO injection influenced microglial activa-

tion in the brain probably leading to an increased immunoreactivity. Immune changes could variably be coupled to behavior: no clear change in depression but a detrimental kind of effect on spatial recognition was observed. Continuous aerobic exercise partly affected cardiac function in this setting, and seemed to counteract to depressive symptoms evoked by ISO treatment.

EXERCISE PROGRAMS TARGETING POSTMENOPAUSAL WOMEN: A NEW NETWORK OF INTERVENTION

TRENTINI, M., FELISATTI, M., POZZATO, E., POMIDORI, L.

Esercizio Vita Center

INTRODUCTION Only a minority of the population, who suffers from chronic diseases, is currently meeting the recommended levels of physical activity. An Italian regional network of certificated gyms (from Emilia Romagna) has been created in order to combine clinical approaches with strategies aimed at fighting against this problem. These centers provide services for people with or without doctors' prescriptions (DGR n. 1154/2011). The purpose of this study is to analyze the adherence and compliance to ExP administered to postmenopausal women, provided by local start-up "Esercizio Vita" center. **METHODS** 86 postmenopausal women (68.4 ± 7.8 yrs) who followed the ExP for the prevention of fall risk (ACSM 2012), were recruited. The sample was followed throughout 18 months (T0-T18) and analyzed for adherence (Wilson et al., 2009); compliance (Insull, 1997); functional assessment 6MWT, Sit And Reach, Berg Scale; type of submission. Finally, subjects had to answer a telephonic questionnaire. **RESULTS** Adherents at the ExP represented 44.2 % of the sample. They have been divided into: compliants (23.7%) and partially compliants (76.3%); no one was non-compliant. Significant improvements were seen in the flexibility of adherents and compliants ($p = 0.0392$) and in the balance of adherents and partially compliants ($p = 0.0026$). The main sending mode was word of mouth (51.2%), except for elderly and low performing subjects (12.8% of the sample) where the main sending mode were doctors' prescriptions (45.5%). The reasons for prolonged periods of non-physical activities were: family commitments (42.6%), health issues (31.1%) and logistic problems (26.3%). **DISCUSSION** As demonstrated in literature, significant improvements were observed in balance and flexibility in adherent postmenopausal women. The importance of this study was to analyze territorial response regarding adherence to ExP in the population who suffers from chronic diseases. We consider that these first signs show how these certificated and combined strategies (clinical and fitness) influence both the public and personal opinion about physical activity. Further studies are needed. **REFERENCES** Deliberazione di Giunta Regionale n.1154 dell' 1 agosto 2011. WORK ABILITY AND WORK-RELATED PHYSICAL ACTIVITY OF EMPLOYEES REGARDING AGE AND OCCUPATION IN A MEDIUM-SIZED BUSINESS

WILKE, C., ASHTON, P., ELIS, T., BIALLAS, B., FROBÖSE, I.

German Sport University Cologne

Introduction Work-related physical activity (PA) and work ability are of growing importance in modern working society. There is evidence for age- and job-related differences regarding PA and work ability. This study analyses work ability and work-related PA of employees in a medium-sized business regarding age and occupation. **Methods** The total sample consists of 148 employees with 116 male (78.4%) and 32 female (21.6%) subjects and a mean age of 40.85 ± 10.07 years. 100 subjects (67.6%) are white-collar workers (WC), and 48 (32.4%) are blue-collar workers (BC). Work ability is measured using the Work Ability Index (WAI). The present study obtained data on the employees PA via the Global Physical Activity Questionnaire (GPAQ). The statistical analysis is carried out with SPSS 21.0. **Results** Analysis of WAI shows higher levels of work ability for WC compared to BC ($p < .001$). Further significant differences were revealed for work-related PA with BC reaching a higher level than WC ($p < .001$). Concerning age no significant differences were found neither for work ability nor work-related PA. Overall, more than half of all subjects meet the current guidelines for physical activity of 2.5 hours per week set up by the American College of Sport Medicine (Haskell et al., 2007). However WC are less able to meet activity guidelines than BC. **Discussion** The present study shows significant differences in work ability and work-related PA regarding occupation. Other research indicates that work ability varies between occupations (Tuomi et al., 2001). The comparison of the age groups shows a similar percentage of low active employees throughout all age groups. Further, older employees with an age between 50 and 65 reveal the lowest percentage of high active employees. This matches other findings (Allender et al., 2008). As a conclusion elder employees are not necessarily less active, yet the present study underlines the evidence so far that elder employees have a higher probability of not meeting current activity guidelines. The results indicate that nearly half of all WC and 75% of BC meet the activity guidelines. **References** Haskell WL, Lee IM, Pate RR, Powell KE, Blair SN, Franklin BA, et al. (2007). EXERCISE, LIFESTYLE AND HEALTH HABITS OF YOUNG ADULTS

AL-NAKEEB, Y.

Qatar University

Introduction This project examined the lifestyle, health habits and risk factors of young adults at Qatar University. It explored the clustering and differences in dietary habits, body mass index (BMI) and physical activity (PA) amongst male and female students, both Qatari and non-Qatari. Low levels of physical inactivity and poor dietary practices have been reported amongst youth living in the Arabian Gulf countries predisposing them to health problems (Al-Nakeeb, 2012 & 2014). **Methods** Seven hundred and thirty two students aged 18–25 year completed a self-reported questionnaire designed to quantify healthy and unhealthy dietary habits. In addition, an objective measure of participants' BMI was calculated and classified for overweight and obesity according to age and gender-specific cut-off points of

the International Obesity Task Force criteria (Cole, et al. 2000). The total energy expenditure per week was calculated based on the metabolic equivalent (MET-min) values of reported activities (Ainsworth, et al. 2000). Results Both males and females had a high prevalence of being overweight and/or obese with low levels of PA, according to well-established international standards. Three clusters were identified based on the students' lifestyle and dietary habits. Cluster 1 (high risk factors), included those who engaged the least in healthy dietary practices and consumed the unhealthiest foods, participated in less PA and had the highest BMI. Cluster 2 (moderate risk factors), included those with considerably more habits falling into the moderate category, engagement in the most PA, the least TV and computer viewing time and had the lowest BMI. Cluster 3 (low risk factors), included those who engaged the most with the four healthy dietary practices, the least with the four unhealthy dietary practices and participated in moderate PA per week. Discussion The findings from this study reaffirm the notion that health practices tend to occur in clusters rather than in isolation (Swinburn, et al., 2011). The study provides valuable data that could be used by policy makers, university management and faculty alike to address issues concerning the health and wellbeing of students, such as limiting the progression of CVD diseases and improving the health of future generations in Qatar. This could be achieved through intervention strategies that lead to changing the built environment and affecting behavioural modification of student's lifestyle and health habits. EFFECTS OF ONE- AND TWO-HANDED BACKHAND STROKES ON BONE MINERAL DENSITY AND CONTENT OF THE DISTAL RADIUS IN POSTMENOPAUSAL TENNIS PLAYERS

WANG, H.S.1, CHEN, H.Y.1, CHAO, H.H.2, LIN, H.S.1, CHIANG, Y.P.3

1:National Taiwan Normal University, 2:National Taiwan University, 3:MacKay Memorial Hospital

Introduction: Previous studies showed that long-term unilateral tennis activity had a positive effect on the bone mineral content (BMC) and density (BMD) of the dominant arm. Hence, the inter-arm asymmetry of bone mass can be observed. Backhand groundstrokes in tennis can be divided into one- and two-handed, but only two-handed backhand strokes induce the bone of non-dominant arm to respond to the mechanical loading. Therefore, the aim of this study was to evaluate the effect of using one- and two-handed backhand strokes on the BMD and BMC of the postmenopausal tennis players. Methods: Bone area, BMC and BMD of the lumbar, hip and distal radius were measured by DXA in postmenopausal women of one-handed backhand tennis players (OTG; 59.2 ± 6.1 years), two-handed backhand tennis players (TTG; 58.2 ± 4.4 years) and swimmers as a control group (SG; 57.1 ± 5.0 years) ($n=14$ per group). Results: There were no significant differences between groups on dominant or nondominant arm of any bone variables. At the ultra-distal radius (trabecular), OTG and TTG had significantly greater inter-arm difference of BMC (13.5 % & 11.8 %) and BMD (14.0 % & 10.4 %) than SG (1.9 % & 1.7 %; $p<.05$). At the mid-distal radius (cortical), OTG had greater inter-arm difference of BMC (13.4 %) and BMD (9.9 %) than SG (3.4 % & 0.4 %), and greater than TTG (3.5 %, $p<.05$) in BMD. At the 1/3 distal radius (cortical), OTG had greater inter-arm difference of BMC (11.4 %) than TTG and SG (4.4 % & 2.9 %, respectively, $p<.05$). Moreover, OTG had higher inter-arm difference of grip strength than TTG and SG (21.6 %, 10.2 % & 10.4 %, respectively, $p<.05$). Furthermore, TTG had significantly higher BMC and BMD of lumbar and femoral neck than SG, and both OTG and TTG had higher BMD of inter-trochanter than SG ($p<.05$). Conclusion: Using two-handed backhand strokes is associated with enhanced BMC and BMD of the nondominant arm, lumbar and hip, which may effectively help to maintain bone mass or attenuate bone loss of specific sites and reduce the risk of future fractures.

GENDER DIFFERENCES IN FACTORS AFFECTING DEPRESSIVE STATE IN JAPANESE UNIVERSITY STUDENTS

SHIMAMOTO, H., NAITO, T., KADOTA, K., FUJITA, K., KOJIMA, R.

Osaka University

PURPOSE Recently, in Japan, lifestyle has shifted to night type. The tendency is remarkable in university students. In addition, depressive tendency has been becoming prominent in this age. Also, it is concerned that physical activity decreases and physical fitness becomes lower. Therefore, it is meaningful to examine relationships among the factors. In this study, we studied the influences of physical activity, physical fitness, daily sleepiness on degree of depressive state and their gender differences in Japanese university students. METHODS One-hundred and twenty-five undergraduate students participated in this study (77 men and 48 women). We measured physical activity level using an accelerometer (LifeCorder LC1, Kenz, Nagoya, Japan) for 2 weeks. The LC measured the daily number of steps (steps per day), 24-energy expenditure (kJ per day), and energy expenditure of exercise (kJ per day). To evaluate the level of endurance fitness, Maximal oxygen uptake (VO_{2max}) was calculated by an indirect method using a cycle ergometer. The VO_{2max} was predicted by the nomogram of Åstrand and Rhyming, a modality that is generally used to predict the VO_{2max}. Depressive tendency and daytime sleepiness was evaluated with questionnaire, PHQ9 (Kroenke et al., 2001) and JESS (Japanese version of the Epworth Sleepiness Scale) (Takegami et al., 2009), respectively. RESULTS The mean of PHQ9 score, sleepiness score, the number of steps, and VO_{2max} were 5.3 ± 3.4 , 10.5 ± 3.7 , 9955.6 ± 3293.3 steps, and 43.6 ± 7.1 ml/kg/min., respectively. A decision tree analysis revealed a gender difference in factors correlated with degree of depression. In male, the degree of depression was positively correlated with activity time and physical fitness, while, in female, there was a significantly positive correlation between the degree of depression and sleepiness. DISCUSSION Our results show that increasing physical activity level and physical fitness increases the degree of depression in male, while, in female, sleepiness has a large influence. Taken together, we concluded that biological mechanism for increasing depression probably is different between men and women. REFERENCES Kroenke K, Spitzer RL, Williams JB.(2001). EFFECTS OF METHODS FOR WARM-UP PRIOR TO BENCH PRESS EXERCISE ON IEMG, MEF AND THE NUMBER OF REPETITIONS IN PECTORALIS AND TRICEPS

YOON, C., KIM, B.K., KIM, D.O., JEONG, H.J., KOO, G.H., SON, J.H., KIM, K.H., KIM, A.R.

Dan Kook University

Introduction The purpose of this study was to find out the effect of different way to warm up prior to bench press resistance exercise on iEMG, MEF and number of repetitions in pectoralis and triceps. Methods Male college students who experienced resistance training for about 1 years were recruited. Three method after warming up(Non Warm-Up, Stretch Warm-Up, Resistance Exercise Warm-Up) on a bench press was performed. iEMG and MEF during bench press exercise were analyzed. For statistical significance, we used t-test and

one way ANOVA. Results First, iEMG in pectoralis major during bench press exercise was recorded the highest when measured after resistance exercise warm-up, and that of non-warm-up was the lowest ($p<.001$). Second, iEMG in triceps during bench press exercise was recorded the highest when measured after non-warm-up, and that of resistance warm-up was the lowest ($p<.001$). Third, pectoralis major's MEF during bench press exercise was found to be the greatest after no warm-up session, but to be the lowest resistance exercise warm-up ($p<.001$). Fourth, triceps's MEF during bench press exercise was found to be the greatest after resistance warm-up session, but to be the lowest after no warm-up session ($p<.001$). Fifth, the number of repetition was the highest during bench press exercise after resistance exercise warp-up session, but the lowest after no warp-up session. Conclusion As a result, warm-up session prior to bench press exercise can lead to higher iEMG in pectoralis major and lower MEF in triceps and therefore can play very important role in performing a number of repetitions. * a1004m@naver.com

EFFECTS OF AEROBIC INTERVAL TRAINING AND MODERATE CONTINUOUS TRAINING ON CARDIAC, MUSCULAR, AND CEREBRAL HEMODYNAMICS SUPPRESSED BY SEVERE HYPOXIA IN HUMANS

WANG, J., HSU, C.

Chang Gung University and Chang Gung Memorial Hospital

Background: Aerobic interval training (AIT) is a more effective modality for improving aerobic fitness than is traditional moderate continuous training (MCT). However, severe hypoxic exposure disturbs vascular hemodynamics. This study investigates how interval and continuous exercise regimens influence hemodynamics and oxygenation in cardiac, muscle, and cerebral tissues during severe hypoxic exposure in humans. **Methods:** Sixty healthy sedentary males were randomized to engage either aerobic exercise training (AIT, 3-minute intervals at 40% and 80%VO_{2max}, n=20) or moderate continuous training (MCT, sustained 60%VO_{2max}, n=20) for 30 minutes/day, 5 days/week for 6 weeks, or to a control group that did not receive exercise intervention (CTL, n=20). Hemodynamic responses to hypoxic exercise (HE, 100 W under 12%O₂ for 30 min) were determined before and after various regimens. A noninvasive bio-reactance device was adopted to measure cardiac hemodynamics, whereas a near-infrared spectroscopy was employed to assess perfusion/O₂ extraction in frontal cerebral lobe ($\Delta[\text{THb}]FC / \Delta[\text{HHb}]FC$) and vastus lateralis ($\Delta[\text{THb}]VL / \Delta[\text{HHb}]VL$), respectively. **Results:** Following the 6-week intervention, the AIT group had a larger improvement in aerobic capacity than the MCT and CTL groups. Moreover, AIT exhibited higher levels of cardiac output, $\Delta[\text{THb}]FC$, $\Delta[\text{THb}]VL$, and $\Delta[\text{HHb}]VL$ during exercise, compared to MCT did. Although acute HE decreased oxygenation of the FC, none of the 6-wk interventions influenced the cerebral perfusion and oxygenation during HE. However, AIT, but not MCT, ameliorated the suppression of cardiac stroke volume and the VL hyperemic response and re-oxygenation rate by acute HE. **Conclusions:** AIT effectively improves cardiopulmonary fitness and increases resistance to disturbance of cardiac hemodynamics by severe hypoxia, concurrence with enhancing O₂ delivery/utilization in skeletal muscles but not cerebral tissues. **References:** 1. COMPARISON OF YOUNG ADULTS BODY BALANCE AND PHYSICAL ACTIVITY

ALEKNAITE-DAMBRAUSKIENE, I.I, DOMEIKA, A.I, BILINAUSKAITE, M.I, GRIGAS, V.I, ŽAGRĀKALIS, T.

1: KUT (Kaunas, Lithuania)

Introduction Physical inactivity levels are rising in many countries with major implications for the prevalence of non-communicable diseases and the general health of the population worldwide (WHO, 2010). The aim of this research is to evaluate relationship between level of physical activity, type of sports and maintenance of body balance. **Methods** 96 young adults of both sexes were included in this study, their ages ranged between 17 and 21 years. All study participants were interrogated by special questioner and their body balance maintenance was tested with "Fall risk test" on Bidex Balance System (BBS). The main aim of test was evaluated the maintenance of body balance. The person under investigation must keep body mass center in the middle of unstable Bidex platform, when instability level decreased from 8 to 1. The test was performed three times for each person, one time duration was 40seconds. **Results** The analysis of the relationship between overall stability index (OSI) and sport type showed that the young adults with aerobic physical activity had better (lower) OSI than persons, who exercised team sports($p<0.05$). Also we found that participants with aerobic physical activity had lower OSI than physically inactive young adults ($p<0.05$). Our study results showed that women OSI was better than men ($p<0.05$). However, there were no statistically significant differences between physically active and inactive people. The strong relationship was found between person's height and OSI ($p<0.01$). Discussion BBS allows evaluating three stability indexes: anteroposterior index, mediolateral index and OSI. Other studies show, that OSI is the most reliable of all three mentioned above (Karimi et al., 2008; Oh et al., 2011). For this reason, present investigation estimates OSI results. The main result of this study there is no differences between active and inactive young adults, however important to say that balance is residual phenomenon which depends on long – term and type of physical activity. Our study as other researchers (Greve et al., 2013) showed better women's maintenance of balance than men's because of neuromuscular and neurophysiological factors. Furthermore, study revealed that relation between height and balance maintenance became more difficult, because of the higher position of center of mass (Alonso et al., 2012). **References** Alonso AC, LunaNM, Mochizuki L, Barbieri F, Santos S, Grevel JM.Clinics (Sao Paulo). 2012 Dec;67(12):1433-41. CALORIC RESTRICTION IMPROVED AGING RESULTED DECLINE OF TESTOSTERONE SECRETION BY DECREASING OXIDATIVE STRESS IN TESTICULAR TISSUES OF MALE RATS

TSAI, H., TSAI, S., KAU, M., FENG, Y.

University of Taipei, National Taipei University of Nursing and Health Science

The previous reports have demonstrated that diet food could affect human physiological and reproductive system, including testosterone production, sperm motility and quantity. Testicular tissue composed a lot of fat and fatty acids, high-fat diet is one component to induce inflammation and oxidative stress which cause to damage testicular function. The purpose is to explore whether calorie-restricted diet could slow down the aging-resulted degenerate of testis in rats. Four and sixteen-month-old Sprague Dawley (SD) male rats were randomly divided into two groups and fed with normal diet (N) and caloric restriction diet (CR) for fourteen weeks. On the age of seven-month (adult) and nineteen-month (old), rats were sacrifice. The blood was collected to measure plasma testosterone by using enzyme immunoassay (EIA). The testicular tissues were collected, weighted, and homogenized to measure the activities of antioxidant enzymes and production of lipid peroxidation and glutathione with commercial kits. All data were analyzed with one way analysis of variance (ANOVA). Where a significant main effect was observed, Duncan's post-hoc analysis was used to locate differences between means. Statistical significance was accepted at $p < 0.05$. The results showed that calorie restriction significantly limited the gain of body weight in both age. Either N or CR, aging resulted significant decline ($p < 0.05$) of reproductive tissue weight, including testis, epididymis and seminal vesicles. Fed with normal diet, old rats showed significant lower plasma testosterone than adult rats, and CR enhanced secretion of testosterone in old rats ($p < 0.05$). Testicular MDA was significant increased by ageing in N but not in CR. As fed with normal diet, aging significantly ($p < 0.05$) decreased the activities of SOD, GPx and GSSG, but significantly ($p < 0.01$) increased the activity of catalase. Calorie-restriction diet improved the activity of SOD ($p < 0.05$), but not altered the activities of catalase, GPx, and GR. The production of GSH was lower in old rats than adult rats, diet did not alter the aging effect on GSH production. In conclusion, both of age and caloric restriction have could effect on reproductive system. Caloric restriction decreased reproductive tissue weight but enhanced testosterone secretion by improving activity of SOD and decreasing production of lipid peroxidation. Maybe caloric restriction could work as an effective strategy to delay onset of aging.

EFFECT OF THE DIETARY SUPPLEMENT SP® ON EXERCISE PERFORMANCE

GATTERER, H., PHILIPPE, M., FRÖHLICH, H., BACHLER, S., MOSBACH, F., BURTSCHER, M.

University Innsbruck

Introduction Super Performance (SP®) is a dietary supplement containing a mixture of substances shown to have some exercise performance enhancing effects (e.g. caffeine, carbonate, branched chain amino acids). Anecdotal reports from athletes suggest the effectiveness of the supplement. However, no scientific data exist so far. Thus, the aim of the study was to investigate the effect of SP® on exercise capacity. Methods Nine sport students performed 3 cycle exercise tests to exhaustion, each separated by 1 week. The first test was considered a familiarization test. In a random order half of the participants performed the second test with SP® supplementation (intake of 40g SP®, 24 and 1 hour before each test) and half with a placebo substance (same amount). During test 3, the order was vice versa (cross-over setting). The cycle test started by 100 watt and workload was increased by 50 watt every 3 minutes. During each test a gas analyses was performed and lactate concentration was determined at the end of each stage. Results SP® supplementation, when compared to placebo, improved maximal power output (299 ± 28 vs. 292 ± 27 watt, respectively; $p < 0.05$), increased maximal lactate concentration (13.4 ± 2.3 vs 10.9 ± 2.1 mmol/L, respectively; $p < 0.05$), and power output at the individual threshold (Dmax) (226 ± 24 vs. 220 ± 21 watt, respectively; $p < 0.05$). Power output at the 4 mmol/l threshold was reduced (220 ± 33 vs. 229 ± 32 ; $p < 0.05$) during the SP® trial. Changes in maximal power output of the cycle tests were positively associated with changes in the maximal lactate concentration ($r = 0.801$, $p = 0.017$). Discussion SP® supplementation increased power output during an incremental exercise test. It seems reasonable to speculate that central and peripheral factors linked to caffeine, carbonate, and branched chain amino acids ingestion might be responsible for the observed performance improvements (Kreider et al., 2010). EFFECT OF DEHYDROPIANDROSTERONE SUPPLEMENT COMBINED WITH WHOLE-BODY VIBRATION TRAINING ON EXERCISE PERFORMANCE AND BIOCHEMICAL PROFILES

CHEN, W.C.1, TSAI, P.H.2, HO, Y.C.3, CHEN, Y.M.4, LI, M.C.4, HUANG, C.C.4

Chang Gung University of Science and Technology

Introduction Whole-body vibration (WBV) is a well-known light-resistance exercise by automatic adaptations to rapid and repeated oscillations from a vibrating platform, which is also a simple and convenient exercise for older adults. Dehydroepiandrosterone (DHEA) is secreted primarily by the adrenal gland and is the most abundant sex steroid. However, the potential benefits of WBV and DHEA supplementation on athlete to changes in body composition, exercise performance, and fatigue are currently unclear. The objective of the study is to investigate the beneficial effects of WBV training and DHEA supplementation on body composition, exercise performance, and physical fatigue-related and biochemical responses in C57BL/6 mice. Methods Male C57BL/6 mice were randomly divided into 4 groups: Sedentary control group with vehicle (SD), DHEA supplementation (5 mg/kg, DHEA) group, WBV group and WBV with DHEA supplementation group (25 mg/kg, DHEA+WBV) for 6 weeks and followed by 6 weeks WBV of 5 days per week. Exercise performance was evaluated by forelimb grip strength and exhaustive swimming time as well as by changes in body composition and anti-fatigue activity levels of serum lactate, ammonia, glucose, and creatine kinase (CK) after a 15-min swimming exercise. The biochemical parameters were at the end of the experiment. Results In our study, mice supplementation of DHEA increase the serum testosterone, muscle mass and have anti-fatigue activity; Whole body vibration (WBV) training increase muscle strength and serum glucose level. However, DHEA supplement combined with WBV training was just slightly increase muscle strength and glycogen. Discussion In the result we find DHEA can enhance the serum testosterone, muscle mass and have anti-fatigue activity and WBV also can increase muscle strength and serum glucose level. But it is interesting that DHEA+WBV just slightly increase muscle strength and glycogen. We doubt that supplementation of DHEA should

need more strengthen training program to achieve the better results. Due to DHEA usually are used to increase muscle mass, strength, and energy. We think it have high potential to improve the aging symptoms, however aging symptoms is very complicated. We will try to find another optimal exercise treatment to solve the problems. For the future study we will modified our WBV training program with resistance training to achieve our expected results. References Chen, Y. M., Tsai, Y. H., Tsai, T. Y., Chiu, Y. CAFFEINE SUPPLEMENTATION HAS NO EFFECT OVER PERFORMANCE IN YOUNG ELITE FOOTBALL PLAYERS

MACKAY, K., DÍAZ-CASTRO, F., PEÑAILILLO, L., ZBINDEN-FONCEA, H.

Universidad Finis Terrae

Introduction: Caffeine has been used as an ergogenic aid in sports performance for at least two decades (Tarnopolsky et al 2010). Studies have hypothesized that due to its stimulant properties on the central nervous system it can be used as an enhancing aid which may improve athletic performance and decrease muscle fatigue. The aim of this study was to observe the effect of the consumption of caffeine on performance in young elite football players before, throughout a 45 min match and after, simulating the end of the first half of a match and observe their performance status for the second half. **Methods:** In a randomized single-blind design, the players (16.4 ± 0.5 years, 69.1 ± 7.5 kg, 175.6 ± 6.6 cm, $13.7\% \pm 3.0$ % body fat) recruited from the national junior chilean team, were given either a capsule of 3 mg · kg⁻¹ b.w. of caffeine or placebo (dextrose) 60 min prior to the match. Match activities was assessed with a GPS system and 5 m (acceleration), 15 m (flying time), and 20 m (maximal velocity) sprints and an agility test was measured with timing gates and photocells before and 5 minutes after the 45 min match. Heart rate was monitored throughout the 45 min game. **Results:** No differences ($P > 0.05$) was observed between the caffeine and placebo group regarding total distance covered (4850.6 ± 231 vs. 4976 ± 386.4 m), sprint number (143.2 ± 10.8 vs. 161.4 ± 22.0), repeated sprints (143.2 ± 11.1 vs. 153.9 ± 24.1), maximal heart rate (198.9 ± 6.7 vs. 197.6 ± 8.0), high intensity zones (zone 5 and 6: 280.5 ± 34.5 vs. 237.6 ± 60.5 m and 178.7 ± 65.6 vs. 157.6 ± 59.1 m, respectively). Acceleration, flying time, maximal velocity, and the agility test showed no differences between groups, before or after the match ($P > 0.05$). **Discussion:** Caffeine administration did not show an ergogenic effect in young elite football players for acceleration, flying time, velocity, agility, or any match activities. Our study is in agreement with the results observed by Pettersen et al. 2014, where no effects in performance was observed in young football players after the consumption of caffeine. Our results conclude that the consumption of 3 mg · kg⁻¹ b.w. caffeine has no effect in preserving performance after 45 min of a football match. References Tarnopolsky, M.A. (2010). DIETARY CAFFEINE INGESTION ENHANCES PERFORMANCE IN AMATEUR MARATHONERS.

ROBLES-RODRÍGUEZ, C.I., FERNÁNDEZ-TORRES, V.J.I., VAZ, C.2, GUTIÉRREZ-MANZANEDO, J.V.1, PONCE-GONZÁLEZ, J.G.1

1Department of Physical Education, Faculty of Education: University of Cadiz, Puerto Real, Spain. 2Centro Andaluz de Medicina del Deporte de Bahía Sur, San Fernando, Cádiz, Spain.

Introduction: Caffeine stimulates lipolysis, which promotes the uptake of fatty acids during exercise, which may improve the performance in endurance sports such as marathon. However, little is known about the effects of caffeine intake on performance in amateur marathoners. Hence, the main aim of this study was to verify if caffeine intake could be associated with improvements in a marathon performance of amateur athletes. **Methods:** Twenty two healthy voluntary unprofessional athletes who participated in 2014 Madrid Marathon were recruited for this study. Finally, the marathoners who managed to finish the race were 16 athletes. Food and drink intake was assessed using a weighed diet record during seven consecutive days of week before of competition with an electronic kitchen scale (HR2395, Philips, Netherlands). All participants were instructed to register all food and beverages in as much detail as possible and to weigh the amounts to the nearest one gram. All the dietary records were analyzed using the nutrient analysis software DIAL V.2 to examine the caffeine intake. In addition, each participant performed a maximal incremental test to exhaustion on treadmill (HP Cosmos Vyasis LE 300 CE; Germany) connected to a gas analyzer (Jaeguer Oxycon Pro, Hoechberg, Germany) and heart rate (HR) monitor (Polar S610, Kempele, Finland) to measure VO₂max and HRmax, respectively. The test started at a speed of 7 km/h and the increase was of 0.1 km/h every 6 seconds (1 km/h every minute). The participants were divided in two groups in accordance with their time race by percentile 50 (fast and slow runners), with cut-point at 3h 33min. Results Mean total intake of caffeine in all participants was 33.9 ± 21.7 mg/day. Fast runners showed higher caffeine intake (43.3 ± 25.4 mg/day) compared to slow runners (23.5 ± 10.6 mg/day) (+89%; $p < 0.05$), even after accounting for VO₂max or age as covariate ($p = 0.03$ and $p = 0.08$, respectively). Caffeine intake was negatively associated with the marathon time race ($r = -0.5$, $p < 0.05$), showing a possible benefit of caffeine on performance. The fast runners showed 14% higher VO₂max in absolute terms versus slow runners ($p < 0.05$), but not in relative values. Absolute VO₂max was associated negatively with time race ($r = -0.6$, $p < 0.05$), but not with caffeine ingestion. **Discussion:** Caffeine intake is associated with better performance in the race. In concordance, Hodgson et al.(2013) and Graham and Spriet (1991) showed respectively that 5 mg/kg and 9 mg/kg ingestion of caffeine 1 h prior to exercise improved endurance exercise performance.

EFFECTS OF COMBINING BEEF, WHEY OR CARBOHYDRATE SUPPLEMENTATION WITH RESISTANCE TRAINING ON BODY COMPOSITION, AND MARKERS OF HEALTH IN COLLEGE ATHLETES.

SEJO, M., LARUMBE-ZABALA, E., ASHRAFI, N., NIELSEN, B., NACLERIO, F.

University of Greenwich

Introduction: Beef is a nutrient-rich, high-quality protein containing all the essential amino acids in proportions similar to those found in human skeletal muscle. The current study aimed at comparing the impact of an oral supplementation with hydrolysate beef protein, whey protein isolate and carbohydrate on body composition, and general markers of health in college athletes. **Methods:** Thirty-three resistance-trained males and females (26.4 ± 7.1 years) were randomly assigned to 1 of 3 groups: hydrolysed beef protein (B n=12), whey protein (W n=9), or non-protein isoenergetic carbohydrate (maltodextrin; CHO n=12). All had to take 20 g of the proteins or carbohydrate, mixed with 250 ml of orange juice, once a day (immediately after workout or before breakfast) during the training period. Body composition, using plethysmography, total cholesterol LDL, HDL cholesterol, urea, uric acid, creatinine, alanine transaminase, aspartate transami-

nase and HNP 1-3 salivary immune-peptides were assessed before and after intervention. Results Only B showed significant increase of fat-free mass ($p=0.007$ d=0.95; +1.8%). Positive trends were observed for W ($p=0.075$ d=0.68; +0.9%) and CHO ($p=0.081$ d=0.58; +1.5%). No changes have been observed for the fat mass in all the three treatment groups. Although the three treatment groups showed no significant differences for all the health blood related markers, compared with the pre intervention values, only B showed a significant decrease in the basal ($p<0.001$; d=0.7; -35.8%) and post workout ($p<0.001$; d=0.7; -26.1%) levels of the HNP 1-3 immune-peptides. Discussion Results demonstrated that combining of 250 ml of orange juice mixed with 20 g of beef protein hydrolysate would maximise fat-free mass, and elicit positive immunity adaptation compared to mixing of orange juice with 20 g of whey protein isolate or 20 g of maltodextrin. Our results support previous positive effect of beef protein in promoting fat-free mass accretion (Negro et al., 2014) and muscle protein synthesis (Phillips, 2012) in adults. Consumption of beef protein supplementation with orange juice after workout or before breakfast would maximise fat free mass gains, and would also promote positive humoral immunity adaptation with no negative effect on the general markers of health. EFFECTS OF HYDROGEN RICH WATER ON INTERMITTENT EXERCISE

DA PONTE, A., GIOVANELLI, N., NIGRIS, D., LAZZER, S.

IRCCS CRO National Cancer Institute, University of Udine

Introduction Recent studies showed a positive effect of Hydrogen Rich Water (HRW) consumption on acid-basic homeostasis at rest. We investigated 2-weeks of HRW intake on repeated sprint performance and acid-base status during prolonged intermittent cycling exercise. Methods: in a single-blind protocol, nine trained male cyclists (age 41.2 ± 7.9 years [mean \pm SD], maximal oxygen uptake [VO_{2max}] 52.6 ± 4.4 ml/kg/min) were provided daily with 2 liters of normal water (pH 7.6, oxidation/reduction potential [ORP] + 230 mV, free Hydrogen content 150 ppb) (CTRL) or Hydrogen Rich (pH 9.5, ORP -450 mV, free Hydrogen 450 ppb) water (HRW) produced by a dedicate device. Tests were performed at baseline and after each period of two weeks of treatment. The sequence of treatments was randomized. The 30-min intermittent cycling trial consisted in ten 3-min blocks, each one composed by 90 sec at 40% VO_{2max}, 60 sec at 60% VO_{2max}, 16 sec all out sprint, and 14 sec active rest. Pulmonary O₂ uptake (VO₂), heart rate and power output were measured during the whole test, while mean and peak power output (PPO), time to peak power and fatigue index (FI) were determined during all the 16 s sprints. Blood Lactate, pH and bicarbonate ([HCO₃-]) concentrations were determined at rest and after each sprint. Results: PPO decreased significantly (mean -10%, $p<0.05$) in the control group from the 5th sprint when expressed as a percentage of the first sprint, and from the 8th sprint when expressed as absolute value, while it remained unchanged in HRW group. Mean power, FI and time to peak power showed no differences. In both conditions lactate levels increased and [HCO₃-] concentration and pH decreased progressively as a function of the number of sprints, showing a trend in favor of lower lactate and higher [HCO₃-] and pH in HRW vs CTRL. No side effects were recorded during HRW intake. Discussion: Two weeks of hydrogen rich water intake seems to improve performance in prolonged intermittent exercise, reducing fatigue and power decrement as happening with acute bicarbonate pre-exercise load. This research on HRW suggests that HRW could be used instead of bicarbonate for improving performance in anaerobic lactic exercise with the advantages of no side effects, no sodium overload and of encouraging correct hydration. PROBIOTIC SUPPLEMENTATION AND GASTROINTESTINAL ENDOTOXEMIA BEFORE AND AFTER THE MARATHON DES SABLES.

SUCKLING, C., ROBERTS, J., PEEPLE, G., GORDON, D., MARSHALL, H., TAYLOR, L., ROBERTS, M.

Anglia Ruskin University, University of Bedfordshire, Aspetar, University of Hertfordshire

Whilst evidence of increased gastrointestinal endotoxemia (GE) has been previously demonstrated during single-day ultra-endurance events, less is known on the prevalence of GE following extreme ultra-events such as the Marathon Des Sables (MDS). The potential benefit of probiotic formulas on gut integrity during ultra-endurance events also requires further investigation. PURPOSE: To assess the impact of probiotic supplementation with or without glutamine on GE prevalence in runners competing in a multi-day ultra-run (MDS). METHODS: Thirty four healthy participants from the 2015 MDS UK cohort volunteered for a 12 week pre-race intervention and were randomly assigned to either: probiotic (PRO; 100mg.d⁻¹ lactobacillus acidophilus) (age 40 ± 3 yrs., weight 79.4 ± 2.0 kg, VO_{2max} 4.2 ± 0.1 L.min⁻¹), probiotic with glutamine (PROglut; 40.5mg.d⁻¹ lactobacillus acidophilus and 900mg.d⁻¹L-glutamine) (age 39 ± 2 yrs., weight 70.6 ± 4.8 kg, VO_{2max} 4.0 ± 0.2 L.min⁻¹) and control (CON) (age 42 ± 3 yrs., weight 79.2 ± 3.8 kg, VO_{2max} 4.0 ± 0.3 L.min⁻¹). Plasma lipopolysaccharides (LPS) (via Limulus Amebocyte Lysate chromogenic endotoxin quantification) were assessed at weeks 0, 12, post-race and 7 days post-race. Performance data was collated from official timing chips. Data presented as mean \pm SE. RESULTS: Mild to moderate GE was prevalent in all groups at baseline (PRO 9.71 ± 0.85 pg.ml⁻¹, PROglut 9.89 ± 1.43 pg.ml⁻¹, CON 9.40 ± 0.57 pg.ml⁻¹; $P>0.05$). Whilst LPS, post intervention, was lower in PROglut there was no significance between groups (9.81 ± 1.47 pg.ml⁻¹ vs 12.80 ± 0.93 pg.ml⁻¹ (PRO) vs 11.72 ± 1.08 pg.mol⁻¹ (CON); $P>0.05$). LPS were evidently reduced 6hrs post-race, but not different between groups (PRO: 7.29 ± 1.41 pg.ml⁻¹, PROglut: 6.95 ± 0.94 pg.ml⁻¹, CON: 9.73 ± 1.39 pg.ml⁻¹; $P>0.05$). Plasma LPS returned to baseline levels 7 days post-race (PRO 7.60 ± 0.95 pg.ml⁻¹, PROglut 10.41 ± 1.04 pg.ml⁻¹, CON 8.57 ± 0.75 pg.ml⁻¹; $P>0.05$). Race performance (hrs:mins) was not significant between groups, despite PRO and PROglut being ~9hrs faster than CON (41:28±2:31 vs 41:58±4:02 vs 50:43±4:38; $P>0.05$). CONCLUSION: Moderate GE was prevalent in all groups pre-race and fell significantly during the short-term recovery period. Despite promising results neither probiotic formula had a significant impact on GE or race performance.

EXERCISE DOES NOT SEEM TO CHANGE QUALITATIVE FRUCTOSE DISPOSAL INTO GLUCOSE OR LACTATE

CROS, J., CLOUET, T., ROSSET, R., TAPPY, L.

University of Lausanne

Introduction Fructose is present in many sport drinks. It is known to be metabolized in a two-step process, involving conversion into lactate and glucose in the liver followed by their oxidation in extra-splanchnic tissues. Glucose synthesis from fructose is energetically more efficient when glyceraldehyde-3-Phosphate (P), rather than pyruvate-lactate, is used as a precursor. The relative activities of these two

pathways remain however unknown. The aim of this study was thus to explore metabolic fate of fructose carbons at rest and during exercise using highly enriched ¹³C fructose and isotopomer analysis of plasma glucose and lactate. Methods Three healthy sedentary volunteers [age (mean±SD): 23±1 y, weight: 67.1±11.3 kg and BMI: 21.8±2.1 kg/m²] were studied after a 3-day weight-maintenance diet [55% carbohydrate (35% starch, 20% sugar), 30% lipids, and 15% proteins]. On the 4th day, fasted subjects ingested a test-meal covering 30% of daily energy requirements (with 35% as fat, 15% as protein, 20% as glucose and 30% as fructose of which 5% was uniformly labelled with ¹³C). Postprandial metabolism was studied for 6 hours by repeated blood sampling. Plasma glucose (M+1 to M+6) and lactate (M+1 to M+3) isotopomer distribution were determined by gas chromatography-mass spectrometry. Gluconeogenesis from glyceraldehyde-3-P was calculated using glucose M+3, and from pyruvate using glucose M+2. Pyruvate-phosphoenolpyruvate cycling was assessed from lactate M+1 and M+2. One subject repeated the experiment while adding a 60-min cycling exercise at 50% VO₂ max immediately after test-meal ingestion (EX). Results In C, plasma glucose isotopomer ratios were 13±4, 10±5, 66±4, 8±1, 2±0 and 1±0 % of M+1 to M+6 respectively, and labelled plasma lactate ratios were 24±6, 18±0 and 57±6 % of M+1 to M+3 respectively. EX did not alter relative abundances, with 10, 8, 70, 7, 2 and 3 % of labelled plasma glucose as M+1 to M+6 and 30, 15 and 54 % of labelled plasma lactate as M+1 to M+3, respectively. Discussion Glucose isotopomer distribution indicate that gluconeogenesis from fructose mainly proceeds from glyceraldehyde-3-P, both at rest and during exercise, and that gluconeogenesis from pyruvate remains low (less than 20%). The absence of glucose M+6 indicates that direct conversion of fructose into glucose does not occur. In addition, production of lactate isotopomers indicate a substantial activity of pyruvate-phosphoenolpyruvate cycling after fructose ingestion. Contact jerry.cros@unil.ch

AEROBIC EXERCISE TRAINING IMPROVES RESPONSE OF CENTRAL BLOOD PRESSURE TO ORAL GLUCOSE LOADING IN OVERWEIGHT/OBESE MEN

YOSHIKAWA, T.1,2, KUMAGAI, H.1,2, MYOENZONO, K.1, TSUJIMOTO, T.1, TANAKA, K.1, MAEDA, S.1

1: University of Tsukuba (Ibaraki, Japan), 2: Research Fellow of Japanese Society for the Promotion of Science

Introduction: Central blood pressure carries important aspects for prediction of future cardiovascular events beyond peripheral blood pressure. Recent studies have shown that central blood pressure decreases after meal intake or glucose challenge, and the postprandial hemodynamic responses are blunted by obesity and insulin resistance. We investigated whether 12-week aerobic exercise training improves the response of central blood pressure to oral glucose loading in overweight/obese men. Methods: Thirteen overweight/obese men (age: 50 ± 2 years, BMI: 27.1 ± 0.7 kg/m², expressed as mean ± SEM) completed 12-week aerobic exercise training. Participants were instructed to perform walking or jogging for 40-60 minutes/session, 1-3 times/week under the supervision of exercise trainers, and were also encouraged to increase physical activity on their own at home to achieve a total of at least 150 minutes/week of moderate-to-vigorous intensity physical activity. Before and after the program, we evaluated anthropometric variables, homeostasis model assessment of insulin resistance (HOMA-IR), and central blood pressure. Central systolic blood pressure (i.e. radial second systolic peak pressure) was assessed using applanation tonometry at fasting and 2-hour after 75-g oral glucose loading. Results: The 12-week exercise training led to a significant weight loss (81.5 ± 2.5 to 78.8 ± 2.5 kg, P < 0.05) and a significant decrease in HOMA-IR (2.4 ± 0.4 to 1.8 ± 0.4, P < 0.05). Regular exercise did not change central systolic blood pressure at fasting state (109 ± 5 to 106 ± 4 mmHg, NS). Glucose loading decreased central systolic blood pressure only after 12-week exercise training (106 ± 4 to 99 ± 4 mmHg, P < 0.01), but not before the training (109 ± 5 to 107 ± 5 mmHg, NS). Additionally, there was a significant difference in central systolic blood pressure at 2-hour after glucose loading between before and after the exercise program (107 ± 5 to 99 ± 4 mmHg, P < 0.05). Discussion: We demonstrated for the first time that 12-week aerobic exercise training improves response of central systolic blood pressure to oral glucose loading in overweight/obese men. Previous studies have revealed that obesity and insulin resistance play key roles in diminishing of postprandial hemodynamic responses. In this study, exercise training led to a significant weight loss and a significant reduction in insulin resistance, indicating these changes contributed to the improvement of central blood pressure regulation after glucose loading. Finally, we suggest that aerobic exercise training has a greater effect on postprandial than fasting central hemodynamics. Contact: yoshikawat@live.jp

VENOUS RESPONSE OF SUPERFICIAL AND DEEP VEINS IN UPPER ARM DURING HEAD-UP TILT

OUE, A.1, OTSUKI, A.2, SAITO, M.1, SADAMOTO, T.2

1: Toyo University, 2: Japan Women's College of Physical Education

Introduction Vasoconstriction in arteries is induced by the increase in sympathetic nerve activity (SNA) via baroreflexes when the posture changes from supine to standing (Escourrou et al. 1993, Kitano et al. 2005). However, it is not understood well whether the increase in SNA during postural change causes the venoconstriction and secondary to decrease in venous compliance. In addition, there are deep and superficial veins in the limb, and the sensitivity of sympathetic nerve stimulation is different between both veins. Based on this, it is hypothesized that venous response during postural change differs between deep and superficial veins. Thus, to clarify our hypothesis, we investigated the change in cross-sectional area (CSA) and compliance of deep and superficial veins in upper arm during head-up tilt (HUT). Methods 10 healthy young subjects were exposed to 0°, 30° and 60° HUT each for 9 min. After the cuff wrapped on upper arm inflated to 60 mmHg for 8 min, CSA in a superficial basilic vein and a deep brachial vein was measured by ultrasound technique during gradual deflation in the cuff pressure (P) from 60 to 0 mmHg at 1 mmHg/s. The relation curve of CSA = β₂ × (P)² + β₁ × (P) + β₀ was determined in each vein and thereafter the venous compliance equation was obtained as the compliance = β₁ + 2 × β₂ × (P). Mean arterial pressure (MAP), heart rate (HR), stroke volume (SV), cardiac output (CO) and arterial vascular resistance in the forearm (AVR) were measured. Results Postural change induced the decrease in SV and the increase in HR and AVR, and these responses depended on angle of HUT. MAP and CO were unchanged. CSA of deep vein decreased during 30° and 60° HUT compared with 0° HUT, although compliance of deep vein did not change. CSA and compliance of superficial vein did not differ among conditions. Discussion The increased HR and AVR during HUT lead to the maintenance of MAP and CO in spite of the decrease in venous return, indicating the increase in SNA via unloading of cardiopulmonary receptors during HUT in our study. At this time, the decreased CSA of not superficial but deep vein was confirmed. Our data revealed that the increase in SNA during HUT caused the venoconstriction but did not decrease

venous compliance, which specifically occurred in deep vein. These results suggest that venous response of deep vein rather than superficial vein might contribute to the control of blood pressure during orthostatic stress. ACUTE CARDIAC AUTONOMIC RESPONSES TO AN INCREMENTAL ISOMETRIC EXERCISE TEST IN PRE-HYPERTENSIVE MALES.

TAYLOR, K.A., WILES, J.D., COLEMAN, D.A., SHARMA, R., O'DRISCOLL, J.M.

Canterbury Christ Church University

Introduction: Arterial hypertension and autonomic dysfunction are significant risk factors for cardiovascular disease. Isometric exercise training (IET) has been shown to reduce resting arterial blood pressure (BP) in normotensive and hypertensive populations; however, the mechanisms responsible remain unclear. Acute changes in autonomic modulation may be mechanistically linked to the reductions in resting BP observed following IET. Therefore, the aim of this study was to assess the cardiac autonomic responses to a single incremental isometric exercise test. Methods: Twenty-four pre-hypertensive male participants were recruited (mean age 44.8 ± 8.4 years, systolic BP 133 ± 5.7 mmHg, diastolic BP 82 ± 6.4 mmHg). Each participant performed an incremental isometric wall squat test consisting of up to five, 2-minute stages of progressively increasing intensity, without rest. Haemodynamic and cardiac autonomic function was recorded at rest, during isometric contraction and immediately during recovery from beat-to-beat analysis of heart rate and BP using a plethysmographic device, the Task Force Monitor®. Total power spectral density and associated low frequency (LF) and high frequency (HF) power spectral components in absolute (ms²) and normalised units (nu) and the LF/HF ratio were determined. Results: Systolic BP significantly increased from rest to during isometric contraction (133 ± 5.7 to 174 ± 18.5 , $p < 0.001$) and significantly attenuated (133 ± 5.7 to 107 ± 23.7 , $p < 0.001$) in recovery. Similar responses were seen in diastolic BP with a significant increase from rest to isometric contraction (82 ± 6.4 to 115 ± 16.3 , $p < 0.001$) followed by a significant reduction (115 ± 3.6 to 61 ± 19 , $p < 0.001$) in recovery. With respect to cardiac autonomic responses, there was a statistically significant increase in LFnu from rest to during isometric contraction ($60.1 \pm 16.8\%$ to $69.3 \pm 13.2\%$, $p = 0.007$), followed by a significant attenuation below baseline in recovery ($60.1 \pm 16.8\%$ to 46.9 ± 13.9 , $p = 0.01$). The reverse was seen in HFnu with a significant decrease from rest to isometric contraction ($39.9 \pm 16.8\%$ to $30.7 \pm 13.2\%$, $p = 0.007$) and significant increase above baseline in recovery ($39.9 \pm 16.8\%$ to $53.1 \pm 13.9\%$, $p = 0.01$). Consequently, these autonomic responses were associated with a significant increase in the LF/HF ratio from rest to during isometric contraction (2.45 ± 0.51 to 3.82 ± 0.52 , $p = 0.02$) followed by a significant reduction below baseline (2.45 ± 0.51 to 1.12 ± 0.14 , $p = 0.046$) in recovery. Discussion: A single isometric exercise test significantly increased arterial BP, which was coupled with a significant residual increase in sympathetic over parasympathetic activity. In recovery, arterial BP significantly decreased below baseline, which was associated with a directionally opposite autonomic response beyond baseline, demonstrated by a significant residual increase in parasympathetic over sympathetic modulation. This acute cardiac autonomic and/or BP response may be important mechanisms attenuating resting BP following a programme of IET.

ELEVATED VISCERAL ADIPOSITY AND ACUTE NEURAL STRESS; IMPLICATIONS FOR CEREBROVASCULAR FUNCTION

HODSON, D.A.1,2, MARLEY, C.J.2, BRUGNIAUX, J.V.2, PETIT, R.3, BLUNDELL, H.3, EVANS, W.3, BAILEY, D.M.2

1:CU (Coventry, UK), 2:USW (Wales, UK), 3:UHW (Wales, UK)

Introduction Obesity has been demonstrated as a risk factor for the development of cerebrovascular disease (Goldstein et al., 2006), with the need to assess the effect of body fat distribution and more importantly visceral adiposity on cerebrovascular function becoming ever more apparent. The effect of a neural stress still remains unexplored within the literature. The aim of the study was to examine if an elevated visceral adiposity impairs cerebrovascular function and if this is further impaired by a neural stress. Methods Ten non-mediated aged matched obese 28 (mean) ± 8 (SD) years and 13 non-obese (22 ± 5 years) participants classified by body mass index (36.9 ± 9.0 vs 24.2 ± 2.9 kg/m², respectively) were recruited. Visceral adipose tissue (VAT) was assessed via computer tomography (GE Hawkeye Scanner), trunk fat percentage (TF) was assessed via dual energy x-ray absorptiometry (Lunnar Scanner) and waist circumference (WC) was measured at the midpoint between the last palpable rib and the top of the iliac crest. Middle cerebral artery velocity (MCAv, Transcranial doppler Ultrasound) and mean arterial pressure (MAP, finger photoplethysmography) were measured pre and post a neural stress (battery of psychometric tests). Cerebrovascular resistance (CVR) and conductance (CVC) were calculated as MAP/MCAv and MCAv/MAP respectively. Data were analysed using a 2-way repeated measures ANOVA and independent t-tests to establish group difference. Correlations were performed using a Pearson Moment Correlations, with significance established at $P < 0.05$. Results Obese had a higher VAT (81 ± 28 vs 42 ± 23 cm²), TF (34 ± 5 vs $26 \pm 7\%$) and WC (115.4 ± 22.8 vs 80.9 ± 8.7 cm) compared to the non-obese ($P < 0.05$). Obese had a higher CVR (1.54 ± 0.40 to 1.55 ± 0.39 vs 1.23 ± 0.37 to 1.32 ± 0.27 mmHg/cm/s) and MAP (91 ± 9 to 87 ± 13 vs 77 ± 22 to 83 ± 11 mmHg) ($P < 0.05$) but no difference ($P > 0.05$) were noted in MCAv (65 ± 15 to 59 ± 14 vs 64 ± 11 to 65 ± 11 cm/s) and CVC (0.69 ± 0.21 to 0.68 ± 0.16 vs 0.99 ± 0.69 to 0.79 ± 0.16 cm/s/mmHg) when compared to the non-obese. Correlations were observed between VAT and MCAv ($r = -0.45$, $P < 0.05$), CVR ($r = 0.47$, $P < 0.05$) and CVC ($r = -0.45$, $P < 0.05$) and TF and CVR ($r = 0.42$, $P < 0.05$). There was no effect of neural stress on cerebrovascular functions. Discussion The findings demonstrate an increase visceral adiposity was associated with impaired cerebrovascular function however there was no effect of an acute neural stress demonstrating the need to further investigations. VERY SHORT-TERM HRV ANALYSIS TO ASSESS AUTONOMIC CONTRIBUTIONS TO HEART RATE RECOVERY AFTER LOW INTENSITY EXERCISE

WEIPPERT, M., BEHRENS, M., BRUHN, S., BEHRENS, K., MAU-MOELLER, A., HUSMANN, F., ZSCHORLICH, V.

University of Rostock

Introduction Heart rate (HR) recovery dynamics are of prognostic value in diseased and athletic populations [1], because they can mirror states of altered autonomic control. While HR analysis alone holds only limited information regarding qualitative adjustments following exercise, very short-term HR variability analysis (vsHRV) [2] might be of additional value as it can reflect different autonomic contributions to HR control. The aim of this study was to assess autonomic contributions to the immediate HR-response following low-intensity exercise using vsHRV. Methods In this randomized cross-over study 22 healthy males (26.5 ± 3.7 yrs, 76.6 ± 7.5 kg, 182.0 ± 6.6 cm) performed one-legged isometric (ISO) and concentric (CON) HR-matched exercises with the right quadriceps femoris muscle at $11.6 \pm 2.8\%$ and $1.3 \pm$

1.1% of isometric maximal voluntary torque for 5 min. Cardiovascular (diastolic, systolic and mean arterial blood pressure, rate pressure product, HR, HRV) and respiratory responses (breathing rate, minute ventilation, oxygen uptake, carbon dioxide production) were measured before (PRE), during ISO and CON, during the first 5 min of recovery (REC 1 – 5) and during 5 min after recovery (POST). HR and vsHRV vagal modulation index HF-Power were analysed for the first 5 adjacent 60 sec periods following exercise cessation. Results HR moderately raised by from 68 ± 8 bpm at PRE to 82 ± 8 bpm during both types of exercise (+21%, $p < 0.001$). While rating of perceived exertion, HRV indices of autonomic control, blood pressures, rate pressure product and respiratory responses were significantly different during the HR-matched exercises, contraction modality itself had no effect on REC and POST periods. After CON HR decreased to 74.7 ± 8.0 bpm at REC 1 (-9%, $p < 0.001$) and further to 69.5 ± 8.2 bpm at REC 2 (-7% vs. REC 1, $p < 0.001$). Similarly, HR declined after ISO to 73.8 ± 8.3 bpm at REC 1 (-10%, $p < 0.001$) and further to 69.7 ± 8.8 bpm at REC 2 (-6% vs. REC 1, $p < 0.001$). HR stayed at this level during REC 3 – 5. In contrast to HR, HF-Power fully recovered within the first 60 sec (REC 1). Discussion Our results indicate a fast parasympathetic and a slower sympathetic component, irrespective of the exercise modality, contributing to the HR recovery after low-intensity one-legged exercise. They further give evidence for vsHRV analysis after low intensity exercise being an appropriate tool to assess distinctive autonomic responses during immediate recovery. 1. Buchheit, M. URINARY NO₂-/NO₃-OUTPUT WHILE PERFORMING A HIGH-INTENSITY INTERMITTENT TRAINING ON CYCLE ERGOMETER

LÜTZOW, M.1, FINKEL, A.1,2, BLAU, L.1, RÖHRICH, M.1, HANFF, E.3, TSIKAS, D.3, MAASEN, N.1,2, MAASEN, M.1,2

1. INSTITUTE F. SPORTS MEDICINE Hannover Medical School, Hannover 2. INSTITUTE F. SPORTS SCIENCE, Leibniz University, Hannover 3. CENTRE OF PHARMACOLOGY AND TOXICOLOGY, Hannover Medical School, Hannover

Introduction There are a lot of recent studies, analyzing the impact of dietary nitrate-supplementation on exercise performance. However the fate of NO₃ in the body is not fully understood. In this study we investigated the changes of urinary nitrate and nitrite excretion in subjects supplemented for 10 days with nitrate while performing a high-intensity intermittent training (HIIT) on a cycle ergometer. Methods Seventeen healthy male volunteers performed the HIIT (45x 30s at 100% - 10W and 30s of 10W, 45) while ingesting either sodium-nitrate [8.5mg/kg body weight/d] (N, n=9) or sodium-chloride [8.5 mg/kg body weight/d] (PLA n=8). Training was individually designed according to the subjects maximal power reached in an incremental exercise test performed prior to the training. Urine samples were taken both before and after the training. Concentration of nitrate, nitrite and creatinine in urine, as well as in plasma (pl) was measured simultaneously by gas chromatography-mass spectrometry (GC-MS) in 100- μ L aliquots by a previously reported method (Tsikas, 2000). Results Mean collection time of urine (time between both samples) was N: 125+/-21.9min, PLA: 118.9+/-13.4min. Urine flow rate was N: 1.95+/-1.3ml/min, PLA: 2.61+/-2.4ml/min. Both parameters are not significantly different. Mean [NO₃]pl differed from N 217.16+/-67.8 μ M to PLA 132.7+/-95.6 μ M ($p=0.059$); [NO₂]pl was 1.53+/-0.199 N and 1.17+/-0.24 in PLA ($p=0.0054$). The urine [NO₃] was in N 3162.3+/-1830.1 μ mol/L and 333.9+/-275.4 in PLA ($p=0.001$). Urine [NO₂] in N was 1.68+/-0.24 and in PLA 1.24+/-0.11 ($p<0.001$). Mean NO₃ output was N 704.2+/-676.7 μ mol; PLA 65.76+/-37.91 μ mol ($p<0.03$). Mean NO₂ output was N 0.388+/-0.25 μ mol; PLA 0.381+/-0.37 μ mol (n.s.). Renal clearance for NO₃ was N 25.61+/-23.8ml/min; PLA 8.5+/-8.5ml/min ($p=0.024$) and for NO₂ N 2.75+/-1.98ml/min; PLA 2.66+/-2.45ml/min (n.s.). The relative excretion for NO₂ was 2% under both conditions. For NO₃ it was 23%+/-14% under NO₃-supplementation and 7%+/-6% under PLA. Discussion Despite different [NO₂]pl the NO₂ output does not differ between both groups. In contrast with NO₃-supplementation the excretion was load dependent. The creatinine clearance was similar under both conditions. Assuming a plasma volume of 3.5l in N, almost the entire NO₃ content of the plasma was eliminated by urinary excretion within 2 hours. Therefore, we postulate a large amount of resynthesizes, and/or a great contribution of NO₃ stores under substitution. M. EFFECTS OF ANABOLIC ANDROGENIC STEROIDS INTERRUPTION AFTER TRAINING AND DETRAINING IN CALCANEUS TENDON: HISTOLOGICAL CHARACTERISTICS

OLIVEIRA, A., BARIN, F., SILVA, L., DA COSTA, O., DURIGAN, J., MARQUETI, R.

UNIVERSITY OF BRASILIA

INTRODUCTION The consumption of anabolic androgenic steroids (AAS) contributes to tendon inertness and rigidity, it alters the biomechanical properties of tendons and increases the potential risk of injury. (Marqueti et al. 2011; Marqueti et al. 2014). However, others potential detrimental effects caused by AAS in tendon remains unclear. The aim of present study was to evaluate the calcaneal tendon histological properties in combination with AAS administration and vertical jump after 6 weeks of ASS interruption and detraining. METHODS Forty Wistar novergicus albinus were randomized in two groups: Immediately After (IA) and Six Weeks After (6W); and in subgroups, equally: sedentary (S), trained (T), sedentary with AAS administration (SAAS), and trained with ASS administration (TAAS). Trained groups performed jumps in water: 4 series of 10 jumps each, a 30-second interval between the series, with 50-80% overload of the animal weight. After 7 weeks, IA group was euthanatized and 6W group stopped both training and AAS treatment. 6W rats were euthanatized after 6 weeks of detraining. RESULTS Immediately after intervention period, SAAS had showed more cells volume density (Vv%) of tendon proper than S in proximal region (PR). In peritendinous sheath, SAAS and TAAS had less adipose tissue than S. But in T blood vessels and cell Vv% in peritendinous sheath increased while SASS and TAAS decreased it. After 6 weeks, cells Vv% of tendon proper increased in T and TAAS, distal region (DR) but it had decreased in SAAS and TAAS in PR; adipose tissue had increased in T in PR and in SAAS and TAAS in DR; blood vessels Vv% had decreased in T in DR, but it had showed high levels in TAAS; and in SAAS, both, in both regions, and in DR of TAAS, the cell Vv% in peritendinous sheath had presented higher levels of content. DISCUSSION The main findings suggest that steroids can negatively affect tendon extracellular matrix (ECM) immediately after AAS administration as decreased blood vessels Vv% and cell Vv% in peritendinous sheath. AAS administration is correlated with higher levels cells Vv% of tendon proper. However, after 6 weeks, AAS, associated or not with training, showed a positive factor to maintain blood vessels Vv% in DR and cells Vv% of tendon proper content in both regions. Lastly, these signals can be associated to tendon recovery because stopping administrating AAS have improved tendon ECM and structure. EFFECTS OF SPRINTER'S ABILITY ON GAZE MOTION AND COGNITION DURING SPRINT OBSERVATION

KURABE, Y.1, NURUKI, A.2, ONO, K.1, YAMAZAKI, Y.1, ICHIKAWA, H.1, YAMASHIRO, K.1, SATO, D.1, MARUYAMA, A.1

1, Niigata University of Health and Welfare/Niigata, Japan/ 2, Kagoshima University/Kagoshima, Japan)

Introduction Action observation of excellent motion is important to acquire superior skills via the process of motor learning. Good sprint skill is evident in the analysis of elite sprinters such as gold medalists. Many sprinters, however, understand that acquisition of good skill is such a challenge that it can be accomplished only with intense practice. Good sprinters might have abilities to trace significant observation points during observation of performance by other elite sprinters and to enhance sensitivity of cognition for self-awareness. We aimed to compare sprinters and novices in terms of their gaze motion during observation of good sprint presented by a slow-motion video and their expressions of self-awareness to the sprint motion. **Methods** Subjects were ten student sprinters aged 18–22 years and eight novices aged 20–22 years. Sprinters were separated into good and poor groups by the result of athlete competition. An eye-gaze tracking system with an infrared light-emitting diode (IR LED) was used to define the coordinate for eye performance during visual sprint observation. The sampling rate (60Hz) was rapid enough to record the smooth-pursuit eye movements covering a 24-inch-wide screen. A sprint converted slow motion (1/10 speed) was presented on the monitor positioned at a distance of 120 cm in front of the subject. The coordinate of the eye movement (resolution, 1024 768 pixels) was superimposed by a synchronous trigger with the slow sprint motion video. We explicitly asked the subjects to concentrate on the images of the motion during the observation. The coordinate of the horizontal axis in the video images was set through a sprint cycle. The coordinate of the vertical axis was divided into three phases as follows: (1) around head, (2) torso and hip, and (3) legs and feet. The number of eye points located in each of the 3 segments were counted throughout the cycle. In addition, we asked the subjects to explain the characteristics of the sprint motion and gaze points of three models of elite sprinters after observation in order to assess the cognition for self-awareness. **Results** The good sprinters concentrated about 31% of the gaze points on (3) during a sprint cycle whereas the poor sprinters did about 10% on this segment, respectively. Novices spent about 73% of time on (1) and (2). Good sprinters particularly explained motions occurred in the segment (3) in the interview. The focus of the explanation of the poor sprinters was on either segment (2) or (3). Novices gave their impressions of sprint motions vaguely. **Discussion** The differences of gaze motion during sprint observation could reflect the sprinter's ability and the sensitivity of cognition for self-awareness to sprint motion. The pattern of gaze points for sprint motion would be significant in terms of improving sprint skill via motor learning. **References** Aglioti et al. EFFECT OF DIFFERENT DOSE OF LEUCINE INGESTION FOLLOW RESISTANCE EXERCISE ON SATELLITE CELL ACTIVATION OF SKELETAL MUSCLE IN RATS

LIM, C.H.1, GIL, J.H.1, JANG, H.Y.1, KIM, C.K.1

1:KNSU/Seoul, South Korea/

Introduction Skeletal muscle satellite cells (SCs) are essential for muscle growth, repair and regeneration in most of all conditions (Brack and Rando 2012, Lepper et al., 2011). And one of essential amino acid, leucine is known that it can promote proliferation and differentiation of SCs (Dai et al., 2015). However, potential influence of dose-dependent leucine supplementation after resistance exercise has not been well studied. Present study investigates potential influence of dose-dependent leucine supplementation follow resistance exercise on satellite cell metabolism in skeletal muscle in rats. **Methods** 10 week-old male SD rats were assigned to sedentary control (CON), 10%(0.135g/kg/wt) leucine supplementation group (L1), 50%(0.675g/kg/wt) leucine supplementation group (L5), exercise group (E), exercise with 10% leucine supplementation group (EL1) and exercise with 50% leucine supplementation group (EL5), total six groups. Ladder exercise was performed the groups involved in exercise intervention. And leucine supplementation was given daily at the same time to all of leucine supplementation groups, 45 min after finishing ladder exercise. SCs and embryonic myosin fiber were identified by immunohistochemistry. **Results** In SCs, E, L1E, and L5E groups were significantly higher than CON group in Pax7/fiber number ($p=.005$, $p=.024$, $p=.016$). However, no difference in the number of Pax7/fiber among these groups. In embryonic myosin fiber, E, L1E and L5E groups were significantly increased in comparison with CON group ($p=.004$, $p=.004$, $p=.000$). Moreover, L5E group is markedly higher than E and L1E group in embryonic myosin fiber ($p=.001$, $p=.001$). **Discussion** It means that resistance exercise is effective stimulus for proliferation and differentiation of SCs. No additional effect by leucine supplementation on SCs proliferation found. However, resistance exercise and high dose leucine supplementation promoted differentiation of SCs by forming embryonic myosin fibers. **References** Dai J, Yu M, Shen Z, Guo C, Zhaoliang S, Qiu X. METABOLIC AND AEROBIC PROFILE OF WOMEN WITH AND WITHOUT NON-ALCOHOLIC FATTY LIVER DISEASE

MONTENEGRO, C.G.P.1,3, PITTA, R.M.1, POLITO, L.F.T.1,2, MAREGA, M.3, CARVALHO, J.A.M.3, CESCHINI, F.1, BOCALINI, D.1, FIGUEIRA JUNIOR, A.J.1

1: São Judas Tadeu University (São Paulo, Brazil), 2: Metodista University of São Paulo (São Paulo, Brazil), 3: Albert Einstein Israelita Hospital (São Paulo, Brazil)

Introduction Non-alcoholic fatty liver disease (NAFLD) is a disease with high prevalence in adults, which has a high evolutionary potential for hepatic steatosis (HS), characterized by the accumulation of lipids in the hepatocytes, representing more than 5% of the liver weight. In the world, the prevalence of HS remains between 10 and 24% in adults of both sex and the physical inactivity, poor nutritional habits and metabolic syndrome are considered risk factors for the development of such histological disorder. **Objective:** The purpose of this study was to evaluate the relationship between the metabolic profile, aerobic fitness and the presence of HS in women. **Methods** We evaluated 454 women (mean age 36.6 ± 6.9 years old), followed at the Continuing Review of Health service of the Israelita Albert Einstein Israelita Hospital- São Paulo - Brazil. The sample was separated into two groups; who had negative diagnosis of HS (weight 61.6 ± 9.3 Kg; height 164.6 ± 6.2 ; BMI 23.0 ± 3.3) and positive diagnosis of HS (weight 69.6 ± 8.3 Kg; height 163.8 ± 5.7 cm; BMI 26.1 ± 3.2 kg/m²) For analysis of aerobic fitness we used the incremental test by the Ellestad / Memorial protocol. For biochemical profile analysis was carried out blood sampling for measurement range glutamyl transpeptidase (Gamma GT), total cholesterol, HDL cholesterol, LDL cholesterol, triglycerides and C-reactive protein. The HS diagnosis was made by abdominal ultrasound. To determine the level of physical activity (PA) was used in the short version of International Physical Activity Questionnaire (IPAQ). Analysis of variance was performed using the Student t test, Mann Whitney U test (significance level: $p <0.05$). The statistical package was the Statistical Package for Social Sciences (SPSS 17.0). **Results** Results showed that 62.1% (N = 282) women are considered inactive and 4.8% (n = 22) of the total sample has HS. There was a signifi-

cant difference in the comparison of aerobic fitness among women with and without a diagnosis of HS (11.2 ± 1 and 12.2 ± 2.4 METS, respectively). Biochemical results indicated significant difference for triglycerides (127.9 ± 50.1 and 87.7 ± 41.6 mg/dL), HDL Cholesterol (53.8 ± 13.2 and 62.5 ± 13.6 mg/dL) and Gamma GT (35.6 ± 23.4 and 18.7 ± 9.3 U/L) in the comparison of positive HS and negative HS, respectively. However there was not significant difference in the same comparison to LDL cholesterol (116.5 ± 31.4 and 104.9 ± 28.0 mg/dL) and CRP (3.7 ± 2.9 e 2.6 ± 4.3 mg/dL). Discussion The group with HS presence showed lower aerobic capacity, higher rates of liver enzymes (reflecting the biggest oxidative stress) and higher plasma levels of CRP and these findings show cardiovascular risk increase with de HS presence. EARLY TREATMENT WITH LOW POWER LASER DECREASE INFLAMMATORY RESPONSE INDUCED ACUTE TRAUMATIC INJURY MUSCLE

DIAS, F.

Universidade do Extremo Sul Catarinense - UNESC

Introduction Studies in recent years have shown that low-level laser therapy (LBP) modulates various biochemical processes, especially those related to increased mitochondrial respiration and tissue repair. The objective was to evaluate the influence of the therapy on acute LBP inflammatory response induced by a traumatic muscle injury model in Wistar rats. Methods Animals were randomly divided into following four groups: control group (CG), muscle injury group (IG), CG + LLLT, and IG + LLLT: laser treatment with doses of 3 and 5 J/cm². Muscle traumatic injury was induced by a single-impact blunt trauma in the rat gastrocnemius. Irradiation for 3 or 5 J/cm² was initiated 2, 12, and 24 h after muscle trauma induction, and the treatment was continued for five consecutive days. Results The results demonstrate that GaAs with a dose of 3 J / cm² irradiation starting 2 hours after muscle injury model decreased all the oxidative stress parameters analyzed such as oxidation of lipids and protein content, antioxidants enzyme activities as GPX, SOD and CAT and the concentration of nitrite in the plasma. The GaAs therapy also induced a decrease in gene expression of IL-6, VEGF and BDNF whereas IL-10 level was increased after 5 days of injury. The behavioral results of motor deficit (open field) demonstrated that animals with muscular injury treated with GaAs (3 J / cm²) had an increase of the distance traveled and the number of surveys compared with muscle injury group Discussion The LLLT caused a reduction in the oxidant and inflammatory biomarkers, indicating that LLLT has a positive biological effect by modulating the redox state and accelerating the recovery of injured tissue. However, when irradiation was started 12 or 24 h after induction of trauma the LBI recovery effect was lost. This suggests that the sooner inflammation and oxidant status is resolved, the faster is the functional recovery of the injured muscle. We suggest that the group that received laser GaAs with a dose of 3 J / cm² irradiation starting 2 h after injury, showed an improvement in locomotion and exploration activity compared to previous results. Taken together, these findings strongly suggest that laser irradiation induced biostimulatory processes that accelerated or resolved the acute inflammatory response, as well as, the oxidant state elicited by the muscle trauma and this effect was dose and time dependente. A CROSS SECTIONAL ANALYSIS OF INFLUENCING FACTORS ON MISPERCEPTION IN SELF-REPORTED PHYSICAL ACTIVITY

RUDOLF, K., DEJONGHE, L., FROBÖSE, I., SCHALLER, A.

German Sport University Cologne

Introduction Misperception of one's own physical activity level is a recurrent problem in rehabilitation and health promotion [1-2]. The present study aims to determine (1) the closeness of agreement between self-reported and objective measure of physical activity; (2) influencing factors on over- and underestimation of physical activity and sedentary behavior; (3) differences in self-estimation between low back pain (LBP) patients and healthy controls. Methods 27 LBP patients and 53 healthy vocational school students wore a triaxial accelerometer (Actigraph GT3X+) during waking hours on seven consecutive days and answered a questionnaire (GPAQ) on physical activity over the same period of time. Bland-Altman analysis was performed for describing the closeness of agreement of the assessment methods. Influence of age, sex and body mass index on misperception of physical activity and sedentary behavior was examined with multiple linear regression. Mann-Whitney U tests were used for detection of group differences. Results Bland-Altman analysis showed poor agreement of self-reported and objective data with significant overestimation of moderate (42 min/day; p=0.003) and vigorous activity (39 min/day; p<0.001). Sedentary behavior was significantly underestimated (-122 min/day; p<0.001). No significant influence of age, sex or body mass index on misperception of physical activity and sedentary behavior was detected. Group differences were found in the estimation of sedentary behavior (p<0.001) and moderate physical activity (p=0.015) with significantly bigger misperception in LBP patients. Discussion Findings based on self-reported physical activity have to be interpreted with caution since significant misperception and sedentary behavior is present in LBP patients and healthy controls. The present results contradict other studies that identified an influence of age, sex and body mass index on the overestimation of physical activity [1]. Further research on influencing factors is needed to identify possible strategies to overcome the problems associated with misperception in self-reports. Moreover, the causality between misperception and LBP needs to be examined. References 1. Godino, J.G., Watkinson, C., Corder, K., Sutton, S., Griffin, S.J., van Sluijs, E.M.F. 1: The University of Tokyo (Kashiwa, Japan), 2: The University of Tokyo (Tokyo, Japan), 3: Fuji Onsen Hospital (Fuefuki, Japan) Purpose This study aimed to investigate the acute effects of pole walking in water on gait and spasticity during walking in a patient with hemiplegia. Methods The subject was a 64-year-old man with a right hemiplegia. He suffered from a left cerebral infarction 12 years previously, which resulted in Wernicke-Mann hemiplegia of the right limb. He performed walking in the pool with two poles for 20 minutes. The water temperature was 36°C. Four-meter walking test was conducted before and after pole walking in water. The subject used a cane during the walking test. A three-axis accelerometer was placed at the level of the second thoracic vertebra and the acceleration signal during walking was sampled at a rate of 100 Hz. The time interval between each step and the maximal acceleration value during foot contact were calculated from the acceleration signal in the vertical (VT) direction for six steps. Surface electromyograms (EMGs) of tibialis anterior, soleus, medial gastrocnemius (MG), rectus femoris (RF), biceps femoris long head, biceps brachii, triceps brachii, and trapezius upper fibers on the hemiplegic side was measured at a sampling rate of 1000 Hz during the walking tests and during pole walking in water. Results In the pre-exercise test, the time interval from the left heel contact to the right heel contact was 2.11 ± 0.29 seconds and from the right heel contact to the left heel contact was 3.30 ± 0.67 seconds. The maximum acceleration in the VT direction was 1.109 ± 0.031 g during the left foot contact and 1.098 ± 0.022 g during the right foot contact. These measurements changed to 0.91 ± 0.03 seconds, 1.25 ± 0.06 seconds, 1.394 ± 0.098 g, and 1.311 ± 0.060 g after exercise, respectively. Locomotor-like EMG activities appeared in MG and RF during and after pole walking in water, although these muscles showed spastic and tonic patterns of EMGs in the pre-exercise test. Discussion The decrease in the time interval and the increase in the VT acceleration indicate that the patient walked more smoothly and faster after pole walking in water. Exercise in water and walking with two poles could decrease postural threat for a patient with hemiplegia, which can decrease muscle spindle sensitivity and affect EMG activities during walking (Horslen et al., 2013). Although the present study is a case report and included only one subject, the results suggest that pole walking in water had an acute neurophysiological effect of decreasing spasticity on a hemiplegic patient, and changed the gait of the patient. EPIDEMIOLOGICAL STUDY OF INJURIES IN A SPANISH HONOR LEAGUE RUGBY TEAM

GARCÍA-FERNÁNDEZ, P.1, GUODEMAR-PÉREZ, J.2, HERVÁS-PÉREZ, J.P.2, CIMADEVILLA FERNÁNDEZ-POLA, E.2, CABALLERO-CORELLA, M.2, TAILLEFER-GARCIA, H.1

1 Department of Physical therapy, Faculty/Power of Sciences of the Health, University Alfonso X Wise (Madrid, Spain); 2 Department of Physical therapy, Faculty/Power of Sciences of the Health, Unive

Introduction The amount and type of injuries in rugby practice depends on the division, if training or competition, player position (front or three quarters) and the time of the season. Rugby is a full-contact sport, so most of the injuries are moderate and mechanisms caused by extrinsic character. The purpose of this prospective investigation was to study the incidence, moment that injuries happen nature and severity of rugby injuries occurring in 32 players in an Honor League team of Madrid during the 2014-15 season. Methods Prospective and observational epidemiological study. For equipment was taken into account a division of honor from Rugby in Madrid. Were recorded prospectively injuries sustained in playing and training throughout the 2014-2015. We create a test for collecting anthropometric and personal data, characteristics of each player and their medical history. As a method for collecting information sheet data collection for epidemiological studies in professional rugby is constructed using the OSICS Result 32 players with an average age of 24.27. From a total of 62 injuries, the most frequent were ligamentous (32.26%), followed by muscle injuries (27.42%), 10 wounds (16.13%), 8 bone lesions (12.90%) and 7 tendon injuries (11.29%). Fronts are more lesions (74.19%) in comparison with the three quarters (25.81%) The most frequent lesions occurred in lower extremities with 26 injuries (41.95%), 12 injuries to the area of the head (19.35%), 11 injuries in upper extremities (17.74%), 8 lesions on the trunk (12.90%) and 5 in the area of the neck (8.06%). The area of the lower limb which suffered the highest number of injuries was knee (9 lesions) (34.62%), 6 in hamstring (23.08%), 5 in ankle (19.23%), 4 in calf muscle (15.38%) and 2 in quadriceps (7.69%). Discussion A total of 62 injuries were sustained, of which 24.19% were minor, 46.77% were moderate and 29.03% were major. The incidence of injury was 5.18 per 1000 player-game hours. This study reflects that rugby is a risk sport activity with a high incidence of injury. It's important for player to know this findings in fact of prepare themselves fisically and have a good treatment for each injury. For every 1000 hours of play in games are produced 29.4 injuries, and only two injuries per 1000 hours of training. This occurs because in practice it reduces contact between players to prevent injuries that physical contact is the main risk factor in this sport.

EFFECT OF A FREQUENT THERAPEUTIC CLIMBING TRAINING ON PHYSICAL ACTIVITY OF PEOPLE WITH MULTIPLE SCLEROSIS

GRAF, A., KERN, C., OBERHOFFER, R.

Technische Universität München

Introduction Previous studies demonstrated that physical activity has a positive effect on the health of people with Multiple Sclerosis (MS). Further, research has shown that people with MS are less physically active (Tzschoppe et. al. 2013, Motl et. al. 2010). Kern (2014) demonstrated that, a special therapeutic climbing program can motivate people with MS to be more physically active. Therefore, the aim of the study was to evaluate the motivation through therapeutic climbing (TC) on the physical activity level in everyday life of people with MS. Methods In this study, 81 people with MS were assessed using the BAECKE questionnaire ("short form questionnaire for the measurement of habitual physical activity", Wagner & Singer, 2003). The questionnaire distinguishes between three categories of physical activity: 'sports', 'working' and 'leisure time activities'. The TC training consisted of 2 hour sessions once a week, while the control group (CG) does not undergo any additional training. However, the work index was ignored in the present study, since 45% of the studied people with MS were not able to work. Results The therapeutic climbing group and control group (TC n=43, CG n=36, exclusion n=3) consist of 73% female and 27% male participants (mean age 48). The mean sport index of TC (2.86 ± 0.67) and the mean leisure time index (3.02 ± 1.07) was higher in comparison to the CG (sport index: 1.91 ± 0.83 , leisure time index 2.60 ± 1.10). There are significant differences in sport index ($p=0.00$) and leisure time index ($p=0.05$). With strong power a high and moderate effect size could be achieved (Sport index: d Cohen 1.26, leisure time index: d Cohen 0.39). Conclusion The results of this study pointed out that TC has a positive effect on physical activity of people with MS in their everyday life. In general the people of the climbing group are more active which could be demonstrated in the higher sporting and leisure time index and they do more different sports in comparison to the CG. The sports index has the highest validi-

ty in context with MS because it contains questions about the duration and intensity of sports. Further research may reveal, if the motivation for the climbing program exists because of a higher affinity to sports in general.

EXERCISE PRESCRIPTION OF MEDITATIVE KARATE KATA CAN IMPROVE PHYSICAL AND MENTAL ABILITIES IN THE SENIOR-AGED INDIVIDUALS

YOSHIHARU, F.

1.Fukui College of Heath Science /2.Dr.FUJIEDA's clinical office

Introduction Impaired cognition and activities of daily living (ADL) have already become a major problem that cannot be ignorable in the highly aged societies. It has been anecdotally told that ascetics of traditional oriental martial arts such as karate or tai chi, tend to have longevities with physical and mental toughness. This study was to investigate the physical and mental effects of karate kata prescription on the senior-aged. Methods Physically active volunteers of 21 Japanese elders with atherosclerotic risks such as hypertension or diabetes mellitus participated in this 12-week intervention. According to the individual's will, they were divided into a kata group (KG: 73.0 ± 6.9 year-old, 2 males, 10 females) and a jogging group (JG: 66.8 ± 5.4 year-old, 2 males, 7 females). We adopted Goju-style karate katas of Sanchin and Tensho that require ascetics to learn proper posture, coordination body movements with respiration and mental concentration. KG was instructed these meditative katas at least twice a week through 12 weeks. JG was prescribed a walking-to-jogging program as a control exercise at similar frequency. Each participant was also asked to join the sub programs, which was consisted of stretching, resistance machine training, cycle ergometer riding or treadmill walking. To esteem the effects on physical fitness, Chair-standing test (CS30) and Six-minute walking test (6MWT) were performed at baseline and after this intervention. Cerebral Exponent Macro (CEM), which was calculated from reading voice by using a chaotic algorism, and heart rate responses against reading aloud tasks were adopted as stress indicators of neo-cortex or autonomic nerve system. New Stroop test II was used for evaluating cognitive functions. Results and Discussions With respect to the safety, all participants of KG accomplished their prescribed program, while 2 females of JG did not due to suffering from lumbago and lower leg disturbance respectively. Worsened atherosclerotic risks were not recognized in both KG and JG. Regarding the effects on physical condition, KG ($p < 0.01$) showed a greater improvement of CS 30 results than JG ($p < 0.05$), although only JG gained 6MWT distance ($p < 0.05$). Increasing of forced expiratory volume was observed in only KG. As to the effects on mental aspect, reductions of heart rate responses against reading aloud tasks were observed in KG and JG (respectively, $p < 0.05$). However, improved CEM with a statistical tendency was indicated only in KG ($p < 0.1$). KG also tended to show an enhancement of the new Stroop tasks ($p = 0.05$). Effects of exercise generally depend on age and baseline conditions of the subjects, and property of the program. Compared with JG, KG revealed favorable changes on physical and mental functions of the senior with lower orthopedic risks despite of older age ($p < 0.05$). We conclude that exercise program based on meditative karate kata could safely improve muscle strength related to ADL, pulmonary function and mental ability among the senior-aged individuals.

CORRELATION BETWEEN FOOT FUNCTION INDEX AND REARFOOT ANGLE WITH THE DOWN STAIRS FUNCTIONAL TASK: STANCE PHASE

YI, L., LOPES, C.F., LUCARELI, P.R.G., RIBEIRO, A.P.

Federal University of Sao Paulo

INTRODUCTION The influence of the feet position during functional tasks has shown great clinical interest. So far it has not been found studies that indicate the relationship between static clinical measures and dynamical feet functional task of down stairs, that is impaired especially when the foot injury are present. OBJECTIVE To verify the correlation between the Foot posture index (FPI) and rearfoot angle during the stance phase of the down stairs functional task. METHODS Twenty two individuals were evaluated, 22 feet, 5 men and 17 women (22.8 ± 3.6 years old, 60.2 ± 12.2 kg, 165 ± 0.08 cm, 21.8 ± 3.0 kg/m²). To evaluate the static clinical measures were used FPI to analyze foot posture [1] and the goniometer to measure rearfoot angle [2,3]. Down stairs functional task evaluation has been performed by feet kinematic analysis using eight cameras for three dimensions capture (sagittal, frontal and transverse). Three trials were registered. Oxford Foot Model [4] and Vicon Nexus® software were used to analyze and process data. The data analysis was applied by Pearson correlation test, with alpha error of 5%. RESULTS When correlate clinical measures, FPI and rearfoot angle, with the variable rearfoot in relation to the ground during the stance phase, were found $r=0.28$ (FPI-sagittal), $r=0.29$ (FPI-transversal) e $r=0.20$ (rearfoot angle-sagittal), as represented in table 1. When correlate clinical measures, FPI and rearfoot angle, with the variable rearfoot em relation to the tibia, during the stance phase, were found $r=0.27$ (FPI-frontal), $r=0.36$ (rearfoot angle-frontal) e $r=0.33$ (rearfoot angle-transversal), as observed in table 2. DISCUSSION Clinical measures, FPI and rearfoot angle, showed mild correlation with the stance phase of the down stairs functional task. The professional that working in the health field should evaluate static and dynamic foot posture separately, to prescribe correct exercises in according to the static and dynamic evaluations. EFFECTS OF ULTRASOUND ASSOCIATED WITH GOLD NANOPARTICLES IN EXPERIMENTAL MODEL OF MUSCLE OVERUSE: ROLE OF OXIDATIVE STRESS

SILVEIRA, P.C.L., ZORTEA, D., SOUZA, P.S., FIDELIS, G.S.P., MENDES, C., SILVEIRA, G.B., DE SOUZA, C.T., PAULA, M.M.S., PINHO, R.A.

Universidade do Extremo Sul Catarinense

Introduction During sports activities, especially those requiring high velocity of movement or displacements, the muscles are exposed to impacts, stresses and forces that can result in injuries, such as strains, ruptures and lacerations, which means that loss of contractile capacity reduces the functional capacity of athletes. Thus, to minimize these effects, the present study suggests, on the basis of an overuse model, that frequent use of ultrasound associated with gold nanoparticles (AuNPs) reduces the inflammation and oxidative stress parameters that are most likely involved in the decreased ability of muscle contraction. Methods Male Wistar rats were randomly divided into five groups: control (C, n: 12); exercise-overuse (EO, n: 6); exercise-overuse plus AuNPs (EO-N, n: 6); exercise-overuse plus ultrasound and saline (EO-U, n: 6); and exercise-overuse plus ultrasound and AuNPs (EO-UN, n: 6). The exercise program consisted of three different

models: low intensity (60 min at 13 m/min, no incline), moderate intensity (60 min at 17 m/min, no incline) and high intensity (inclination - 16% until exhaustion at 17 m/min—eccentric exercise). Exercise sessions were performed for 21 consecutive days, and one exercise model was applied daily in the following sequence: low intensity, moderate intensity and high intensity. Ultrasound was used with and without AuNPs in all animals an hour before the workout from day 4. Twenty-first days after the behavioral tests, blood collection and testing of oxidative stress and inflammatory parameters were performed. Results The overuse model promoted behavioral changes and increased creatine kinase, superoxide dismutase and glutathione peroxidase activity, as well as the levels of superoxide, nitrotyrosine, nitric oxide, thiobarbituric acid reactive substance, carbonyl, tumor necrosis factor α and interleukin-6. These values were significantly decreased by AuNPs and by AuNPs plus ultrasound. Catalase activity remained unchanged and the glutathione level increased significantly after exposure to AuNPs plus ultrasound. Discussion This study found that the overuse model was effective in altering behavioral patterns, promoting muscle damage and increasing levels of muscle inflammation and oxidative stress. The results presented also suggest an important effect of ultrasound plus AuNPs, possibly by reducing the inflammatory response and increasing glutathione levels. Thus, the combined use of ultrasound and anti-inflammatory agents such as AuNPs represents an important alternative in the treatment of muscle injuries. Contact: psilveira@unesc.net

INTRODUCTION OF EXERCISE THERAPY DURING DIALYSIS AND PHYSICAL/PSYCHOLOGICAL EFFECTS

INAGAWA, T.

NTT Medical Center Tokyo

Objective The objective of this study was to perform a self-exercise program in maintenance dialysis patients attending our hospital and discuss the physical and psychological effects. **Subjects** Eligible subjects were 16 patients who received haemodialysis at our hospital between June 2012 and December 2015 and were able to continue exercise for 6 months or longer. **Methods** Wearing wrist/ankle straps with heavy weights or ceramic bands, the subjects did self-resistance exercise during dialysis. They did the exercise three times weekly for about 30 minutes, mainly on the legs. The effect of exercise was measured by muscle strength of pectoralis major muscle and quadriceps as well as physical function using 30-sec chair stand test, Timed "Up and Go" test, and 6-minute walk test, and the results were analyzed using average \pm standard deviation. In addition to these measurements, all patients were interviewed by nurses. **Results** Eligible subjects were 16 patients, including 11 males and 5 females. At the time of start of the study, their age ranged from 49 to 89 years (71.9 ± 10.2 years) and the period of maintenance dialysis ranged from 0.8 to 16.6 years (5.9 ± 5.4 years). Six months after start of exercise, the muscle strength of pectoralis major muscle and quadriceps increased significantly. Also, 30-sec chair stand test, Timed Up and Go test, and 6-minute walk test improved significantly. In the nurse interview, 13 answers, including multiple answers, could be gained. Thirteen responders said, "Can walk more easily"; thirteen responders said, "Can do exercise more easily than expected"; nine responders said, "Have less anxiety that muscle and body strength is decreasing"; ten responders said, "Others praise how much I have made efforts"; and seven responders said, "Glad to get good scores at physical strength test". **Discussion** It was demonstrated this exercise program could improve physical function such as muscle strength, ability to walk, and balance ability significantly. These answers from interview by nurses suggested that patients with incurable kidney diseases had positive thinking, positive awareness of oneself, and willing to survive that they had never had. As described above, adding a factor of "exercise" to dialysis could achieve physical and psychological effects, which may improve their activity of daily living and quality of life.

PO-CPP-26 Training & Testing 2

EFFECTS OF AN EIGHT-WEEK PLYOMETRIC TRAINING PROGRAM ON SPRINT AND JUMP PERFORMANCE IN ADOLESCENT ELITE RUGBY PLAYERS

ULRICH, G.1, LANGE, K.1, CESELKA, J.2

University of Heidelberg

1: Institute of Sport and Sport Science (University of Heidelberg, Germany), **2:** German Rugby Union (Germany) Introduction Plyometric training can enhance explosive contractions thus improving explosive movements, such as throwing and sprinting (Markovic et al., 2007). As sprinting is a key factor for success in rugby, the objective of this study was to determine whether an 8-week plyometric training program would enhance selected aspects of jump and linear sprint performance in adolescent elite rugby players. Methods 16 german adolescent elite male rugby players (age, 15.7 ± 0.7 y; height, 172 ± 6 cm; body mass, 73.5 ± 3.0 kg) were randomly assigned between a control (C, n=8) and an experimental group (E, n=8). Due to the off-season, C had no training at all and E solely performed plyometric training once a week (for 90 minutes over 8 weeks with stepwise increasing volumes - approx. 650 plyometric jumps per session). Before (baseline) and after 8 weeks (post), jump performance was checked via jump heights in the Counter-Movement-Jump (CMJ) and in the Squat-Jump (SJ) as well as via reactive strength index (flight-time \times ground contact time-1) in the Drop-Jump (DJ-RI). Linear sprint performance was assessed via split-times required for 5m, 10m and 30m. Results A two-way ANOVA with repeated measures revealed that after 8 weeks E significantly ($p < 0.01$) improved CMJ height (baseline: 44.0 ± 5.8 cm; post: 49.9 ± 5.3 cm), SJ height (baseline: 38.7 ± 5.2 cm; post: 46.4 ± 6.0 cm), DJ-RI (baseline: 2.60 ± 0.41 ; post: 3.40 ± 0.44) as well as all sprint sections (e.g. 30m, baseline: 4.38 ± 0.24 sec; post: 4.12 ± 0.24 sec). In contrast, compared to baseline, all jumps and sprint sections were impaired in C after 8 weeks, however not significantly. Compared to C, after 8 weeks E had significant higher CMJ and SJ heights (each $p < 0.05$), DJ-RI ($p < 0.01$) and an improved 0-5m sprint time ($p < 0.05$). Prior to the 8-week training regimen, no significant differences between C and E were detected across all tested parameters. Discussion The main finding of this study was that an exclusive 8-week plyometric training program has the potential to markedly enhance jump and linear sprint performance in adolescent elite rugby players. We suggest that the gains in the linear sprint performance resulted from an enhanced jump performance due to an improved power development of the musculature involved in reactive jumping tasks. References Markovic, G., Jukic, I., Milanovic, D. & Metikos, D. (2007). Effects of sprint and plyometric training on muscle function and athletic performance. LONG-TERM TESTING OF ECCENTRIC STRENGTH IN ELITE FEMALE AUSTRIAN SKI RACERS AND ITS RELATIONSHIP TO RACING PERFORMANCE

PATTERSON, C., PÉREZ DEL RÍO, A., RASCHNER, C.

University of Innsbruck

Introduction Eccentric leg strength is considered a crucial factor in alpine ski racing success (Hoppeler, 2015). The purpose of this study was to examine long-term isokinetic eccentric leg strength characteristics in elite Austrian female alpine ski racers, and to determine if eccentric strength was related to ski racing performance. **Methods** The strength testing data of 23 female members of the Austrian alpine ski team who were tested over 5 consecutive years in preseason fitness tests were examined. The athletes were tested on a Con-Trex leg press for unilateral eccentric leg extension strength (ECC). Range of motion was set at knee angles of 85° to 120°. The FIS points at the end of each of the 5 seasons for the best event of each athlete were used to determine ski racing performance. A repeated measures ANOVA with 2 factors was utilized to test if ECC and FIS points changed over the 5 seasons, and if ECC and FIS points interacted ($p < 0.05$). **Results** The mean FIS points for the group was 12.6 ± 7.2 in season 1, and improved to 9.5 ± 6.8 in season 5. The mean ECC of the group was 29.0 ± 5.0 N.kg $^{-1}$ in season 1, and 30.2 ± 5.0 N.kg $^{-1}$ in season 5. ECC did not statistically change over the 5 seasons but performance based on FIS points did significantly change over the 5 seasons. There was no significant interaction between the 2 factors of ECC and FIS points. **Discussion** Over the 5 years the athletes improved in their FIS points but isokinetic eccentric leg strength did not change and was not found to effect racing performance. There is very little published research relating strength and power test results to athletic performance (Abernathy, et al, 1995). The complexities of ski racing make this even more difficult. Performances are not only determined by the physical abilities of the athlete. Ski characteristics, ski preparation, start number, and snow conditions are examples of important factors which influence performance but are not related to athlete physical preparation. Isokinetic testing is reliable (Abernathy, et al, 1995). Isokinetic tests can determine limb strength asymmetry, and compare concentric and eccentric strength. The results of unilateral isokinetic strength tests can determine if athletes have muscle structural balance (injury prevention), and if athletes are physically fit after a knee injury, which is unfortunately common in ski racing. However, strength tests have little value in predicting ski racing performance. **References** Abernathy, P., Wilson, G., & Logan, P. (1995). Sports Medicine, 19, 401-417. Hoppeler, H. (2015). EFFECT OF LOW INTENSITY CYCLING EXERCISE SUBSEQUENT TO UPPER-BODY RESISTANCE TRAINING ON MUSCLE HYPERSTROPHY IN UNTRAINED MEN

TOMIYA, S., KIKUCHI, N., YOSHIDA, S., NAKAZATO, K.

Nippon Sport Science University

Introduction Many athletes perform low-intensity exercise such as cycling and running as methods of cool-down subsequent to resistance training and/or matches (Reilly and Ekblom, 2005). Concurrent upper-body strength training (arm-curls) and lower-body sprint interval training had lower increases of muscle cross-sectional area (CSA) and 1 repetition maximum (RM) compared to strength training and endurance training that was performed immediately after resistance training (Kikuchi et al., 2015). The purpose of this study was to examine whether or not low intensity cycling exercise and subsequent upper-body strength training influences training response of muscle strength and hypertrophy. **Methods** Fourteen subjects were randomly assigned to the experimental group: one group performed low intensity (55% of maximum oxygen consumption, 30 minutes) endurance cycle training immediately after arm resistance training (IA group, n=7) and another group performed low intensity endurance cycle training and arm resistance training on separate day (SD group, n=7). A supervised progressive arm resistance training (RT) program designed to induce muscular hypertrophy (10 reps at 75% 1RM of bilateral arm-curl exercise) was performed in 8 weeks, with training carried out 3 times per week. **Results** Significant increase in CSA from pre- to post- test was observed in the SD group ($p = 0.001$, ES= 0.84, 95%CI -0.31 to 1.86), and in the IA group ($p = 0.004$, ES= 0.45, 95%CI -0.64 to 1.48). Significant increase in 1RM from pre- to post- test was observed in the SD group ($p = 0.025$, ES= 0.91, 95%CI -0.24 to 1.94), and in the IA groups ($p = 0.001$, ES= 2.38, 95%CI 0.88 to 3.54). Higher percent change of CSA was observed in SD group ($12.1 \pm 4.9\%$) compared to IA group ($5.0 \pm 2.7\%$, $p = 0.029$). **Discussion** In conclusion, our data suggested that low intensity cycling exercise immediately after upper-body resistance training systemically influences training response of muscle hypertrophy, but not on separate day. **References** Reilly T, Ekblom B. (2005). J Sports Sci, 23, 619-627. Kikuchi N, Yoshida S, Nakazato K. (2015). J Strength Cond Res, 1064-8011. Contact [shigeto.tomiya@gmail.com]

COMPARISON OF THE MAXIMUM TOE FLEXOR MUSCLE STRENGTH BETWEEN KENDO ATHLETES AND COMPETITIVE SWIMMERS

MIYAMOTO, A.I., TAKAMI, Y.I., NAKANO, M.I., YANAGIYA, T.I.

Juntendo University

Introduction Foot is the only region of the body to contact with the ground during standing with lower limb. And it also has the important roles, for instance, attenuating shocks of ground contact, supporting the body weight, controlling the posture, and so on. In the recent studies, toe flexor muscle strength (TFS) is often used as one of the indices of toe flexors. Moreover, TFS is suggested to be important for the improvement of sport performance (Goldmann et al. 2013). However, there is little information about athlete's TFS and differences due to sports events, as far as we know. Therefore, we investigated the difference in TFS between Kendo athletes and competitive swimmers, because the manners of gravity in these event are quite different. Swimming is one of the typical anti-gravitational events, in contrast, Kendo is applied large forces to the lower limbs during repeated hopping steps of forward and backward on the floors, besides barefoot. So, the purpose of present study was to compare the TFS of Kendo athletes with competitive swimmers. Our hypothesis was that Kendo athletes showed higher TFS than competitive swimmers, because of the differences gravitational effect. **Methods** Subjects were male of Kendo athletes ($n=30$) and competitive swimmers ($n=13$). TFS in both feet was measured using a specifically designed dynamometer (T.K.K.3364, Takei Scientific Instruments) in standing. All subjects were gripped the grip-bar with their toes at maximal effort for 3 seconds. Measurements were performed twice in each foot. The TFS value was adopted the averaged of the maximum values for each foot, then relative of body weight was calculated (TFS/Wt). All data were presented in the form of mean \pm SD. An unpaired t-test was used to examining the differences between two groups. The level of significance was set at $p < 0.05$. Results TFS was 245.1 ± 52.8 N in Kendo athletes, and 281.1 ± 59.8 N in competitive swimmers. TFS/Wt was 3.57 ± 0.66 N/kg in Kendo athletes, and 3.92 ± 0.90 N/kg in competitive swimmers. TFS and TFS/Wt were no significant differences between two groups. **Discussion** Present study was investigated the difference in TFS between Kendo athletes and competitive swimmers. It is thought that Kendo is applied large force to the lower limbs. In practice,

there is a report that stamping foot was contact to ground from forefoot, and vertical ground reaction force was more than 10 times the body weight at the contact. On the other hand, swimming has no ground impact. From their differences, we hypothesized that TFS is higher in Kendo athletes than competitive swimmers. However, results of this study were no significant differences. It was contrary to the hypothesis. This result was implied that TFS fulfill important roles for sports performance, not only the case of contact with the ground. Reference 1 Goldmann J. P. et al., J Sports Sci 2013, 31(4): 424-433. DETERMINATION OF LACTATE, HEART RATE AND VENTILATORY TURN POINTS IN INCREMENTAL LEG PRESS EXERCISE

ALMER, CH.1, MÜLLER, A.1, KORINEK, M.1, TSCHAKERT, G.1, HOFMANN, P.1

University of Graz

Introduction The lactate shuttle theory precisely describes an exercise intensity dependent three phase response of balanced or non-balanced muscle lactate production and local or systemic lactate oxidation (1). Glycolytic production, distribution in muscles and other tissues and finally reconverting lactate to glucose as an energy source to spare glycogen, underpins the link between glycolytic and oxidative metabolism (2). The aim of this study was to determine lactate, ventilatory and heart rate turn points to analyse metabolic and cardiorespiratory responses performing an incremental leg press exercise test. Methods 6 male students (25.8 ± 5.2 years, 71.7 ± 7.6 weight) performed a 1-RM test to obtain maximal leg press performance. Several days later subjects performed an incremental exercise test (IET) on the leg press up to exhaustion. The weight per step was calculated as 30% of 1-RM / 15 to reach maximal workload in about 15 steps. Each step lasted 1min with a cadence of 30 reps/min. Turn points for lactate (LTP1, LTP2), ventilation (VT1, VT2) and heart rate (H RTP) were calculated by means of a linear regression break point analysis. HR as well as gas exchange data were measured continuously. Blood samples were taken before and after a warm up step, after each succeeded step, and after cool down phase to obtain blood lactate concentration (La). Results According to a three-phase response LTP1 (1.1 ± 0.4 mmol.l⁻¹) and LTP2 (1.5 ± 0.3 mmol.l⁻¹) could be determined at an intensity of 18.8 ± 3.9 %1RM and 28.4 ± 3.0 %1RM (50.3 ± 10.1 %Pmax and 75.9 ± 4.9 %Pmax) respectively. Depending on Pmax, %PLTPI,2 were similar to standard IETs. Ventilatory threshold VT1 (27.5 ± 7.2 l.min⁻¹) was 18.6 ± 3.8 %1RM (49.9 ± 11.3 %Pmax) as well as VT2 (40.9 ± 11.6 l.min⁻¹) was 29.1 ± 2.9 %1RM (77.9 ± 5.8 %Pmax), were not significantly different from LTP1 and LTP2. Heart rate turn point (H RTP) was 139 ± 5.4 min⁻¹ and the maximum heart rate was 159 ± 11.3 min⁻¹. Intensity at LTP2 and H RTP as well as LTP2 and VT2 were significant correlated ($r=0.95$, $p<0.01$; $r=0.98$; $p<0.01$) and not sign. different. Discussion It was possible to determine LTP1 and LTP2, VT1, VT2 and H RTP in the incremental leg press test. Lactate, heart rate and ventilation curves were comparable to standard IETs. These results indicate that knowledge and application of the lactate shuttle theory may also be applied for strength endurance exercise. References (1) Hofmann, P. & Tschakert, G. (2011). DEVELOPMENT AND VALIDATION OF THE ROPE-CLIMBING ERGOMETER FOR PHYSICAL FITNESS TESTS OF UPPER LIMBS

ARAKAWA, H., KUMAGAWA, D., FUJISAKI, I., OZAWA, Y., ISHIGE, Y.

International Budo University

Introduction The ergometer for testing physical fitness has been extensively used by many researchers and practitioners. The cycle ergometry has become the most prevalent in both laboratories and practical scenes. Meanwhile, no gold standard has been established for upper limbs, suggesting a room for further development of an ingenious ergometer that will expand the options of measurements under near-competitive conditions within a specific sport. The purpose of this study was to develop and verify the rope-climbing ergometer (rope-ergometer) which can assess physical capabilities in a pulling movement of upper-limbs. **Materials and Methods** The rope-ergometer developed in this study is designed for use in a sitting posture. On this devise, a subject pulls a rope downward with both hands alternatively. This modality is similar to the commercially available rope-climbing training machine ("VLT Rope Trainer", Marpo Kinetics Inc.) which does not have an ergometry function. As resistance, mechanical load was generated to the rope by an electromagnetic braking equipment. The levels of load were controlled by a microcomputer system. In total 100 staged levels can be discretionarily set by operators. The tension of the rope for each instant of time was measured by a load cell device attached to the pulley above user's head, whereas the velocity was estimated with a rotary encoder. The tension and velocity of the rope were recorded with a sampling rate of 100 Hz. All control regulations were carried out by the microcomputer. Fourteen healthy male participants participated in the qualification experiment. The participants performed eight sets of maximal effort rope-climbing trials. The load levels were set at 0, 3, 6, 9, 12, 15, and 18 out of 100, respectively. The exercise duration was less than 10 seconds. The tension and the velocity were smoothed with a 9-sample simple moving average, and then the instant power was calculated. **Results and Discussion** The rope-pulling force increased with an increment in the load level (e.g., level 0: 15.0 ± 4.2 kgf, level 18: 39.1 ± 2.6 kgf), whereas the velocity decreased with an increment in the load level (e.g., level 0: 1.87 ± 0.23 m/s, level 18: 0.66 ± 0.20 m/s). The rope-pulling power reached a peak at the load level 9 (320 W \pm 123), and declined with a decrement and an increment in the load level, respectively (e.g., level 0: 276 ± 89 W, level 18: 254 ± 87 W). **Conclusion** The results of the qualification experiment suggest that the rope-ergometer developed in this study can be validated for testing maximal power in the upper limb exercise, taking the velocity-force relationship of a muscle into consideration.

THE EFFECTS OF HIP THRUST TRAINING ON STRENGTH AND POWER PERFORMANCES OF LOWER EXTREMITY

KUN-HAN, L., CHIH-MIN, W., YI-MING, H., ZONG-YAN, C.

Physical Education Office, National Tsing Hua University, Hsin Chu City, Taiwan

Introduction Hip joint, serves as the biggest and powerful joint in lower extremity, plays very important roles in many essential functional movements, like running and jumping. Hip thrust is the modern training way to enhance the strength of hip muscles, especially gluteus maximus (Contreras et al., 2011). However, less evidence was provided the benefits of the hip thrust training on strength of lower extremity and its functional performances. Therefore, the study aimed to analyze the effects of hip thrust training on strength and power performances of lower extremity. **Methods** Ten healthy collegiate students (173.1 ± 4.6 cm; 69.8 ± 11.6 kg; 19.9 ± 0.8 yrs) participated in 8 weeks of hip thrust training program (50-80% 3RM, 8-20 rep, 4 sets, 30-90 second rest between sets). Four students (170.7 ± 5.2 cm; 67.3 ± 12.9 kg; 21.4 ± 1.6 yrs) served as the control group. They repeated same tests and were asked to continue usual activities and not to start any exercise program. Both groups did not have any experience of hip thrust training. The tests, including vertical jump high, long jump, 30 m sprint, squat strength (1 repetition maximum, RM) (SS) and hip thrust strength (3RM) (HTS), were performed after identical warm-up exercises. **Results** After training, we found significant improvement in SS ($p<.05$) and HTS ($p<.05$), but not in vertical jump high, long jump and

30 m sprint. No changes were observed in the control group. Furthermore, the improvement in SS ($37 \pm 15\%$) was positively correlated with that in HTS ($44 \pm 27\%$) ($r=0.65$, $p=0.02$). Discussion The 8-weeks hip thrust training improved squat strength but not power performances of lower extremity. This is the first study to investigate the effects of hip thrust training on functional performances. The interesting finding was that the squat strength could be enhanced by the progressive hip thrust training program. We further analyzed the improvement of squat strength was associated with the increasing strength of hip extensors. Although hip extensors are highly activate during sprint and functionally important for powerful movements (Jamie et al., 2014), there were no changes in jumping and sprint performances after hip thrust training in our study. In conclusion, hip thrust training could be an assisted way to enhance squat strength, but not an optimum way to improve functional power movements.

THE STUDY OF SCAPULAR STABILIZER MUSCLES STRENGTH AND FLEXIBILITY IN WEIGHTLIFTERS

VANASANT, T., PHOPANYASAK, N., SITILERTPISAN, P.

Sports Authority of thailand

Introduction Weightlifting requires high power and musculoskeletal strength. Overtraining and poor joint movement for a long time may cause high risk for scapular muscles imbalance and dysfunction. Thus, the aim of this study want to examine the scapular stabilizer muscles strength and flexibility between weightlifters athletes and non-athletes Methods Eighty-one volunteers (38 males, 43 females) with age 18.81 ± 2.37 years, weight 67.74 ± 19.75 kg, height 160.82 ± 7.78 cm and a body mass index of 26.54 ± 8.10 kg / m² were participated in the study. They were divided into weightlifters group (23 males, 25 females) and control group (13 male, 20 female). At first, muscles flexibility were assessment by using physical method. After that, scapular stabilizer muscles strength included lower trapezius, internal and external rotator were measured via handheld dynamometer (Lafayette, USA) and surface electromyography (BTS FREEEMG, Italy). The scapular stabilizer muscles strength and flexibility data between groups were compared by using the Independent t-test at $p < 0.05$. Results The study found that shoulder flexibility in weightlifters was significantly less than control group ($p < 0.05$). Weightlifters group demonstrated significantly more scapular stabilizer and upperlimb muscles strength than control group ($p < 0.05$) in dominant and non-dominant side. Discussion Our study showed Weightlifters muscles inflexible that may be due to the effect from strenuous strength training program. As shoulder muscles are very tight, It affects the strength of shoulder rotator muscles in weightlifters group. This information could be used for the baseline of muscular flexibility training and scapular muscles stabilization exercise program. Thus, the flexibility training programs should be instructed for the weightlifters. In addition, the scapular stabilizer training may be suggested for supplementary program. Especially the lower trapezius, internal and external rotator strength training should be added in weightlifting training to manage muscle dysfunction and gain maximum lifting performance. MUSCLE ACTIVATION AND LACTATE RESPONSE TO ACUTE WHOLE BODY VIBRATION WITH BLOOD FLOW RESTRICTION IN HEALTHY UNTRAINED MEN

CAI, Z., CHENG, W., WU, C.

National Sun Yat-sen University

Introduction The occlusion training, resistance exercise combined with blood flow restriction (BFR), has largely been reported to increase muscle mass and strength (Pope et al., 2013). However, whether an alternative passive occlusion training model, using whole body vibration (WBV) exercise combined with BFR (WBV+BFR) would elicit adaptive response is unclear. It has been suggested that increased in muscle activation and metabolic products are important factors in the adaptive response to occlusion training (Pope et al., 2013). Therefore, this study aimed the acute effect of WBV+BFR on muscle activation and blood lactate (LA) responses. Methods Eight healthy untrained male adults participated in this study and performed two exercise sessions, including WBV+BFR and WBV in a repeated measures crossover design that separated by one week intervals. The frequency and amplitude of WBV was set at 26Hz and 4mm respectively. The WBV protocol was designed by 10 sets for 1 min, with 1-2min rest between the vibration sets. In the WBV+BFR session, participants wore a BFR device around the proximal portion of thigh muscles and inflated the device to a pressure of 140 mmHg. During each exercise session, electromyography (EMG) signals of participants' thigh muscles of the dominant leg were collected, and rating of perceived exertion (RPE) was also assessed. Blood lactate was determined pre-exercise and post exercise. Results EMG from rectus femoris and vastus lateralis during WBV+BFR were significantly higher than that of WBV (55.96 ± 5.31 vs. 42.41 ± 6.68 ; 87.65 ± 5.28 vs. 67.86 ± 4.72 μ V, respectively, $p < .05$). RPE value was higher for WBV+BFR than WBV (5.69 ± 0.49 vs. 3.84 ± 0.45 , $p < .05$). Both WBV+BFR and WBV exercise caused significant increase in LA (0.61 ± 0.09 to 4.68 ± 0.43 vs. 0.46 ± 0.07 to 3.44 ± 0.36 mmol/l, $p < .05$), and WBV+BFR significantly elicited the LA responses much higher than that of WBV post exercise ($p < .05$). Discussion The study shows that adding BFR device while performing WBV would increase participants' RPE and primary muscles activation. In addition, LA response was manifested by this model. It is speculated that adding BFR device on WBV, the primary muscles tend to be aroused more motor units to accommodate the greater effort as blood flow is restricted. Result of this study was similar to those in the previously studies using external resistance in which the working muscle is further activated (Sartorio et al., 2011), and led to an increase in LA concentration (Yasuda et al., 2009). In conclusion, the passive WBV+BFR model can produce addictive muscle contraction response in addition to WBV. It may be suitable for people who seldom do regular exercise. ADAPTATIONS IN THE CARDIAC SYSTEM OF AN OLYMPIC DOWNHILL SKIING CHAMPION: A 6-YEAR ECG CASE-STUDY.

EICHBERGER, P.1, FOMIN, R.2, NASEDKIN, V.2, ABUBAKIROVA, Y.3, LIEBICH, M.4

1:Swiss Ski Federation/Switzerland, 1:Eichberger-Sports-Consulting/Austria 2:Omegawave/USA, 3:Institute for Informatics and Automation/Russia, 4:Otto von Guericke University (Magdeburg, Germany)

Adaptations in the Cardiac System of an Olympic Downhill Skiing Champion: A 6-year ECG Case-Study. Introduction: The contribution of the cardiac system in optimizing the training process and performance results of highly skilled skiers remains unexplored. The purpose: to observe changes in particular ECG parameters which represent adaptations in the cardiac system of an Olympic champion in response to specific training and competition loads. Methods: The study involved a 2010 Olympic champion downhill skier. Bioelectrical heart activity was recorded by ECG using Omegawave 3 technology (USA). ECGs were recorded regularly for 6 years from 2004 up to the 2010 Olympic Games, where the athlete achieved the best results of his career. Initial data contained over 800 ECG assessments. ECGs were recorded at rest using standard limb leads I, II, III (including aVR, aVL, aVF), and unipolar chest leads V2, V3R, and V6. Recording time was at least 128 sec. and took place before training or competition (5:00 to 10:00 am). A comprehensive analysis of ECG intervals and amplitude characteristics was then conducted. Heart rate variability (HRV) analysis was also used to assess the state of the autonomic nervous system (ANS). Statistical analysis was performed using SPSS 23 (USA). Results: With increased sports preparedness, changes were observed in the basic function of both the cardiac system and ANS regulatory mechanisms. Over the course of the study, a general decrease in wave amplitude R, S, T in lead V2, and S and T wave amplitude in lead V6 was observed ($p<0.001$). The width of the QRS complex in V6 abduction significantly increased. In standard ECG leads the width of P and T waves was significantly increased, and the amplitude of the waves Q, R, S, T decreased ($p<0.001$). HRV parameters showed various wavelike trends depending on the period of preparation, all within normal range. A tendency towards decreased activity of vagal regulation and increased role of the sympathetic branch of the ANS was observed. However, during the year prior to the Olympic Games, both ECG and HRV parameters showed opposite trends. In ECG leads V2 and V6, wave amplitude R, S, T increased. In HRV indices, the activity of the parasympathetic branch of the ANS and autonomous cardiac rhythm control loop increased (RMSSD, Total Power, HF), and the sympathetic branch decreased (amplitude of the mode and Tension Index). Discussion: ECG and HRV parameters are physiological markers that reflect the biological cost of forming adaptational changes in response to daily training and competition stressors. Frequent monitoring of these changes can be useful for optimizing the training process. Contact: eichberger.peter@yahoo.com

NEUROMUSCULAR ADAPTATIONS TO 2½-WEEK HIGH-INTENSITY INTERVAL TRAINING WITH COMPRESSION GARMENTS IN FEMALE ICE HOCKEY PLAYERS

PIIRAINEN, J.M.1, KINNUNEN, J.V.1, PIITULAINEN, H.2

1: University of Jyväskylä 2: Aalto University

INTRODUCTION High-intensity interval training (HIIT) is commonly used training method to improve performance. HIIT increases power and speed performance (Naimo et al. 2015), possibly because of improved motor control. Utilization of the compression garments (CG) during the exercise may enhance performance and recovery (Hamlin et al. 2012), and thus may enhance the training response. We studied neuromuscular adaptations to HIIT and possible benefits of the CG for training response. METHODS Fourteen female ice-hockey players were divided into compression garment (CG, height 165 ± 6 cm, weight 68 ± 12 kg, age 22 ± 4 years, N = 6) and non-compression garment (no-CG; height 166 ± 5 cm, weight 66 ± 13 kg, age 22 ± 3 years, N = 8) training groups. Both groups performed 2.5 weeks HIIT by running in 9.5 degree uphill. Rate of force development (RFD) was measured from plantar flexors. Levels of voluntary motor drive (V-wave/maximal M-wave) and spinal alpha-motoneuron excitability (H-reflex/20% M-wave) were quantified during maximal voluntary contraction from soleus muscle before and after the training. Light cells were used to measure acceleration and maximal speed during on-ice performance. RESULTS Both groups improved RFD (CG $15.6 \pm 12.3\%$, $p < 0.05$; no-CG $14.9 \pm 18.9\%$, $p < 0.05$) during the training. In addition, V-wave responses increased by $20.3 \pm 14.7\%$ in CG group ($p < 0.05$), while in no-CG group increment was only $13.4 \pm 15.9\%$. No significant changes were observed in H-reflex amplitude (CG $0.0 \pm 48.6\%$; no-CG $4.5 \pm 36.5\%$), nor in on-ice skating performance. DISCUSSION A significant HIIT-training-induced increase in V-wave amplitude implied increased or better-synchronized neural motor drive through the spinal alpha-motoneurons during maximal isometric contraction (Aagaard et al. 2002). However, utilization of CG didn't cause additional improvement in the force production, even though the level of voluntary motor drive was enhanced. It can be suggested that, possible benefits of CG should be confirmed with studies utilizing longer training periods and including more muscle groups such as quadriceps muscles. METABOLIC AND CARDIOVASCULAR RESPONSES DURING GROUP SUSPENSION TRAINING

GIANCOTTI, G.F.1, FUSCO, A.1, DI CECIO, F.1, DI MICCO, G.1, RODIO, A.1, CAPRANICA, L.2, CORTIS, C.1

1 University of Cassino and Lazio Meridionale; 2 University of Rome "Foro Italico"

Introduction Suspension Training (ST) is a recent form of bodyweight resistance training. ST produced higher muscle activations with respect to traditional exercises secondary to muscle activity used to maintain body stability and balance (McGill et al, 2014; Snarr et al, 2014) and a single training session could be used to improve core stability, strength, flexibility and endurance (Dudgeon et al, 2015). At present, no information is available on ST energy cost during group sessions. Therefore, the aim of this study was to evaluate metabolic and cardiovascular responses during group ST. Methods After signing their informed consent of participation, 18 college students (11 male, 7 female; Age: 26.2 ± 4.5 years; Height: 168.2 ± 9.3 cm; Weight: 68.5 ± 12.7 Kg; BMI: 24.0 ± 2.5) novel ST practitioners volunteered for the study. After a familiarization period, Heart Rate (HR) and Oxygen Consumption (VO_2) were continuously recorded by portable metabolic

system (Cosmed K4b2) during 18 different training sessions (Duration: 42.5±7.3min). Energy expenditure was expressed as Metabolic Equivalents Task (MET). Analysis of Variance (ANOVA) was used to evaluate gender-related differences ($p<0.05$). Results Although no difference in HR emerged for gender (Males=68.3±6.9 %HRmax, Females=70.7±5.1 %HRmax), differences emerged for VO₂ (Males=17.9±2.6 ml/Kg/min, Females=15.2±2.6 ml/Kg/min, $p<0.0474$; Males=1.32±0.16 l/min, Females=0.88±0.13 l/min, $p<0.0001$) and MET (Males=5.1±0.8, Females=4.3±0.7, $p=0.0474$). Discussion According to ACSM guidelines (2014), findings suggest that ST could be classified as a moderate-to-vigorous intensity exercise. Furthermore, ST could be used to increase energy expenditure (about 250 Kcal for males and 200 Kcal for females) and to improve cardiovascular efficiency. However, further research is needed to evaluate the effects of ST protocols on metabolic and cardiovascular capacities. References ACSM 2014, Guidelines for Exercise testing and prescription. 9th Ed. FEASIBILITY OF POSTURAL SWAY CALCULATION IN THE EQUINE ATHLETE USING WEARABLE SENSOR TECHNOLOGY

EGAN, S., MCKEOWN, D., MCGRATH, D.

University College Dublin

Introduction Wearable sensor technologies have begun to revolutionise the fields of sport and health. While the use of these technologies are rapidly becoming the "norm" in areas such as sports performance analysis and physical activity monitoring, the field of equine sports has been slower to uptake. A huge opportunity exists to harness these technologies in the training of athletic horses. The aim of this study was to assess the feasibility of measuring postural sway using on-body inertial sensors. The long-term aim of this research would be to use this measure for longitudinal monitoring of fatigue/recovery of horses in the field. Methods A body-worn inertial sensor containing a tri-axial accelerometer was attached to one healthy horse at the highest point of the croup (posterior iliac spine) using a custom made attachment. The aim was to capture a "quiet standing" trial lasting at least 40s. Three quiet standing trials were recorded. Acceleration data were sampled at 51.2 Hz and band-pass filtered between 0.1-10 Hz. The initial 5 seconds of data were removed, and the subsequent 45 seconds of data were considered for further analysis. Cumulative horizontal acceleration was calculated using the medial-lateral (ML) and anteriorposterior (AP) acceleration vectors, by twice integrating the acceleration signal. Low frequency drift was reduced using a second-order polynomial fit and subtracting the mean amplitude of the signal before and after each integration procedure and then high pass filtered at 0.1 Hz. Results Only one trial out of three was suitable for analysis due to the horse's idiosyncratic standing movements. The ranges of AP and ML displacement (i.e. 0-80mm) produced a stabiogram similar in shape, but differing in magnitude to previous work using force plates (Clayton and Nauwelaerts, 2012). This is expected, given the distance of the inertial sensors from the centre of pressure changes beneath the horse's hoof. Discussion The sensor set-up and capture protocol successfully detected "quiet" postural sway in the equine animal. Our experiment confirmed the challenge of consistently capturing quiet standing data of sufficient length. It would therefore be preferable to perform long-term monitoring of postural sway while the horse is 'sleeping', due to the animals sophisticated 'stay apparatus', allowing it to remain standing in a resting state. Such data could be used to monitor the state of health of the equine athletes' motor control system, similar to emerging approaches in human movement. References Clayton, HM, Nauwelaerts S. Equ Vet Med (2012) 44, 5, 550-553

PERFORMANCE & METABOLISM IN MICE

THOMASSON, R.

IRMES - EA7329

Introduction, Maximal oxygen uptake (VO₂ max) represents, both humans and animals, the integration of the cardiovascular, respiratory and muscular systems ability to take up and utilize oxygen during exercise, was applied to man in the nineteen-twenties by the Nobel Prize Archibald Hill. These measurements are intrinsically interesting in order to initiate comparative physiologic's analyses and they are frequently of critical importance for investigations of evolution of physiological traits. The Performance & Metabolism in Mice (PMM) facility provides comprehensive, standardized or advanced, customized characterization of performance and metabolism in mouse models. Materials and methods 10 Swiss and 15 C57 female mice (3-4 months old) were tested for oxygen consumption (VO₂) on a treadmill. Our equipments, independent and parallel treadmills (TSE, Frankfurt, Germany), allowing the VO₂, VCO₂, RER (VCO₂/VO₂) and the energy expenditure measurement by indirect calorimetry. During the exercise, automatic VO₂ and VCO₂ measurements are made without additional constraint on the animals (measured every 1s). VO₂peak was determined as the highest value of VO₂ achieved over 15s and expressed relatively to body and lean mass (measured by RMN) in ml.kg⁻¹.h⁻¹. All mice performed an incremental test (0.01 m.s⁻¹ increment each 15s). Results Regarding the lean mass, Swiss mice (28.73±1.78g) were bigger than C57 mice (18.43±0.93) with a lean mass ratio lean mass/mass decreased (66.69±9.96% vs 79.37±2.83%). Swiss VO₂peak relatively to lean mass (11.38±0.61ml.kg⁻¹.h⁻¹) were significantly different from C57 (9.57±0.52ml.kg⁻¹.h⁻¹; $p<0.01$). Concerning Vmax, we obtain a similar result between Swiss and C57 mice (respectively 0.63±0.10m.s⁻¹ and 0.71±0.08m.s⁻¹; $p<0.01$). Discussion The metabolic exploration facility of PMM performs specific, on-demand experiments as well as comprehensive metabolic analyses to evaluate in vivo the energy balance in mouse. This exploration is performed under either basal condition or energy challenges using standardized techniques for the detection of phenotype in energy metabolism. It provides users with the techniques and scientific support used to design experimental protocols as well as for the development of new techniques to investigate metabolism. Besides the metabolic aspects, treadmills allow us to induce a stress that can, on one hand, reveal pathologies and/or rising adaptations, and on the other hand create muscle damage stimulating the regeneration processes.

EFFECT OF EXERCISE INDUCED HYPOHYDRATION ON BODY COMPOSITION MEASUREMENTS IN ACTIVE AND ATHLETIC SUBJECTS

KLASS, M., RIVIÈRE, V., BOOGHS, C., CARPENTIER, A.

Université Libre de Bruxelles

Laboratory for Biometry and Exercise Nutrition, Université libre de Bruxelles (ULB, Belgium) Introduction Body composition is frequently assessed in active subjects and athletes to quantify its impact on performance or the effect of different kinds of physical/nutritional interventions. However subject hydration varies along the day and in between days due to physical activity which may induce errors in body composition estimation (1,2). Therefore the aim of present study is to quantify the effect of an exercise induced hypohydration on body

composition measurements using different methods. Methods Thirteen active (7 males) and 13 athletic (7 males) subjects took part in the experiments. Their body composition was assessed using anthropometric methods (skinfolds), multi-frequency bioelectrical impedance analyser (M-BIA) and dual-energy X-ray absorptiometry (DXA) before and after a run on treadmill that induces a body weight decrease of 2%. Correlations between individual weight losses and body composition changes were calculated. For DXA, segmental changes and correlation between initial percentage of fat mass and body composition changes was also calculated. Results Athletic subjects presented a significantly lower initial fat mass percentage (13%) compared to active subjects (24%) [$P<0.05$]. Average body composition changes between pre and post exercise are expressed in percentage of pre-exercise values. The lean mass measured by DXA and M-BIA decreased post-exercise by 2.5 and 1% respectively [$P<0.01$]. The fat mass was reduced post-exercise when measured using DXA (2.3%) and M-BIA (8.2%) [$P<0.01$]. Body fat percentage estimated using M-BIA was reduced by 5% [$P<0.01$] and did not change for DXA. Skinfolds sum and fat percentage calculated using Durnin and Wormersley equation combined to Siri equation (DWS) were slightly reduced (1.7%) post-exercise [$P<0.01$]. For DXA and M-BIA, fat mass changes were correlated with weight loss [$P<0.05$], whereas correlation was not significant for lean mass. Body fat percentage changes were significantly correlated with weight loss for DXA but not for M-BIA and DWS. For DXA, decreases of fat mass and lean mass were located respectively in the trunk and in trunk and legs. Initial percentage of body fat mass was correlated with changes of fat and lean mass. Discussion Changes of fat mass and lean mass due to exercise induced hypohydration were predominantly located in the trunk and were dependent on the method used. It also appears that initial body composition, which differs between athletic and less active subjects, may influence errors induced by hypohydration. THE RELATIONSHIP BETWEEN COACH FEEDBACK AND SELF-PERCEIVED SPORT COMPETENCE IN COLLEGIATE MALE FOOTBALL PLAYERS

AMBE, H., MURASE, K.

Hokkaido University of Education

Coach feedback significantly contributes to players' sport competence associated with intrinsic motivation. However, limited research has examined this relationship with observation in real sport-coaching settings. Therefore, the purpose of this study was to investigate the relationship between coach feedback and players' self-perceived sport competence in actual coaching contexts. One coach and 23 players of a male university soccer club participated in this study. The coach's feedback to the players was recorded for 10 weeks using VTR and, subsequently, categorized into seven domains: 1) positive, 2) negative, 3) instructive, 4) questioning, 5) organizing, 6) friendly, and 7) other. Both before and after receiving coach feedback, players were asked to complete a questionnaire, which consisted of 10 subscales: (1) pass and control decision-making, (2) speed, (3) dribble skill, (4) physical strength, (5) endurance, (6) defense skill, (7) leadership, (8) motivation, (9) long kick skill, (10) heading skill. A significant relationship between soccer players' self-perceived competence and coach feedback was found. The results reveal that frequency of positive feedbacks, such as praise and encouragement, are negatively associated with pass and control decision-making as well as dribble skill. The results further indicate that collegiate male soccer players tend to draw on self-comparison and other internal processes more than positive coach feedback to evaluate their competence. Alternatively, a positive association between negative feedback, such as scold, and pass and control decision-making competence was also found. In competitive sports setting, the coach and players would share their common goal as a victory. In this case, players who received negative coach feedback understand the coaches' intent behind that. As a result, negative coach feedback seems to improve players' self-perceived competence in pass and control decision-making areas.

POSITIVE SOCIAL-EMOTIONAL CONDITIONS, BASIC PSYCHOLOGICAL NEEDS AND WELL-BEING IN HIGH PERFORMANCE ATHLETES

CASTILLO, I.I, GALILEA, B.2, BALAGUER, I.I

1: Sport Psychology Research Group. University of Valencia (Spain) 2: Unitat d'Esport i Salut. Consell Català de l'Esport (Spain)

Introduction Based on Self-determination theory (Deci & Ryan, 2000) in this study a model was proposed testing associations between athletes' perceptions of the protective environmental resources on their training centre (belonging to the centre, caring relationships, high expectations and meaningful participation), psychological need satisfaction (competence, autonomy and relatedness), and well-being (subjective vitality, life-satisfaction and self-esteem). It was hypothesized that athletes' perceptions of socio-emotional conditions of the training centre will be positively related to psychological need satisfaction, which in turn will be positively related to well-being. Methods A total of 139 high level Spanish athletes from different sports (52 men and 87 women) ranging in age from 14 to 18 years ($M = 15.7 \pm 1.12$), participated in this study. All participants practice sport five days a week ($M = 5.35 \pm 0.66$), for over four hours per day ($M = 3.78 \pm 1.04$). Participants completed a multi-section inventory including the Spanish adaptations of several questionnaires: a) Subscales of Caring Relationships, High Expectations and Centre Meaningful Participation from the Resilience Youth Development Module (Bernard & Slade, 2009); b) Subscale of Centre Connectedness from the California Healthy Kids Survey (WestEd, 2006); c) Subscale of Perceived Competence from the Intrinsic Motivation Questionnaire (McAuley et al., 1989; Balaguer et al., 2008); d) Scale of the Need for Autonomy (Reinboth & Duda, 2006; Balaguer et al., 2008); e) The acceptance subscale of the Need for Relatedness Scale (Richer & Vallerand, 1998; Balaguer et al., 2008); f) Subjective Vitality Scale (Ryan & Frederick, 1997; Balaguer et al., 2005); g) Subscale of Self-esteem of Self-Description Questionnaire-III (SDQ-III, Marsh et al., 1994; Balaguer et al., 2008); and h) Satisfaction with Life Scale (Diener et al., 1985; Atienza et al., 2000). Results Structural Equation Modeling analyses showed that athletes' perceptions of belonging to the centre ($\beta=0.39$), and opportunities for meaningful participation in their centre ($\beta=0.29$) positively predicted their psychological needs, which in turn contributed to improve subjective vitality ($\beta=0.31$), life satisfaction ($\beta=0.36$) and self-esteem ($\beta=0.27$). Discussion Overall, findings support the importance of providing positive social-emotional conditions in the training centres to promote positive functioning and favoring the athletes' well-being. THE CHALLENGES AND COPING STRATEGIES EXPERIENCED BY TAIWANESE PROFESSIONAL BASEBALL PLAYERS IN THE UNITED STATES

CHI, L.K., CHEN, M.C., CHEN, S.Y.

National Taiwan Normal University

Introduction The purpose of this paper was to identify the challenges and coping strategies experienced by Taiwanese baseball players who played professional baseball league in the United States. Methods Semi-structured interviews were conducted to explore the adaptation experience with nine overseas players (ages 21-29 years, experiences 2-6 years), one sport agent, one coach, two team sport psychologists, one retired USA player, and three administration staffs, total 17 participants and 24 times interviews (7 players were interviewed twice at 1-year interval to follow their adaptation experience). The players competed at different levels: Rookie, Short A, 1A, Advantage A, 2A and MLB. Grounded theory principles were used for data collection and analysis. Results The results showed that the challenges encountered by Taiwanese baseball players in the United States included six inter-related main themes: insufficient English abilities, post-relocation loneliness, cultural differences, dynamic environment, performance pressure, and intensive competition. Among the challenges, insufficient English abilities were identified as the most impactful theme since it is related to relocation loneliness, dynamic environment, understanding new culture, and communication to teammates and coaches. Therefore enhancement of English ability was suggested most often among the participants. Cultural differences and dynamic environment were considered important at the first one or two years, and after that how to deal with performance pressure and intensive competition became prominent issues among all challenges. Coping strategies were suggested according to different challenges. Four conclusion was drew from coping strategies: 1) accumulation of experience was the foundation of adaptation process, 2) support from others was the most commonly used strategy, 3) the importance of taking initiatives, and 4) psychological skill trainings were suggested to help players better deal with performance pressure. **Discussion** The findings highlighted the complexity among these six themes of challenges and the potential areas sport psychologists could work on. Recommendations are provided to smooth the adaptation process for Taiwanese baseball players in the United States.

THE RELATIONSHIP OF SELF DETERMINATION MOTIVATION TOWARDS PHYSICAL ACTIVITY, TIME SPEND SEDENTARY AND DEPRESSION SYMPTOMS IN RHEUMATOID ARTHRITIS PATIENTS

YU, C., FENTON, S.A.M., KITAS, G.D., DUDA, J.L.

Kingston University

The Relationship of Self Determination Motivation Towards Physical Activity, Time Spend Sedentary and Depression Symptoms in Rheumatoid Arthritis Patients Introduction Rheumatoid arthritis patients has been associated with a heightened risk of cardiovascular disease (Metsios et al., 2009) but also indicators of compromised mental health such as high anxiety and depression (Treharne, et al., 2005). Participation in moderate-to-vigorous physical activity (MVPA) has been found to accrue health benefits in this clinical population, and research evidence suggest that less time spent sedentary (ST) may also help RA patients enhance their well being. People with RA, however, tend to not engage in sufficient levels of physical activity (PA). Thus, it is important to better understand the motivational determinants of PA in this clinical population. Pulling from Self-Determination Theory, this study examined the associations between self determination (SD) toward exercise, objectively measured PA and ST, and depressive symptoms (DS) in RA patients. Method Valid data were obtained from 55 out of 115 patients with RA (age=55±13, 37 females) from the baseline assessment of a RCT. The accelerometer data were downloaded, reduced and analysed by the Activlife 6.0 software. Descriptive and path analyses were on variables derived from both questionnaire and objectively measured PA and ST. The Relative Autonomy Index (RAI) was employed as the indicator of the RA patients degree of SD regarding their exercise behaviour. Results The results revealed RA patients to spend more ST (499.11 ± 68.71, minutes per day) than the general population and do not meet the recommended level of MVPA (17.24± 15.80) during the 7 day assessment protocol. RAI positively correlated with moderate PA ($r=.30$, $p<.05$) and MVPA ($r=.30$, $p<.05$), and negatively correlated with DS ($r=-.38$, $p<.01$). Path analysis indicated that an amended model demonstrated acceptable fit to the data. Discussion RA patients spend more ST and engage in less MVPA than recommended which echoes previous research findings (Yu et al., 2015). Findings revealed more SD to be positively related to daily MVPA and negatively linked to DS among patients with RA. The unexpected associations between ST and DS may need to be examined further in the future. Limitations of this study in terms of sampling and the use of a cross-sectional design are addressed. THE INTERNAL TASK HIDDEN IN THE MOVEMENT TROUBLE IN COLLEGE ATHLETES: ANALYSIS BY THE LANDSCAPE MONTAGE TECHNIQUE

KATSUHIKO, K.

Hokkaido university of education

Introduction The purpose of this study is to examine the similarities between troubles in physical movement and the internal tasks in college athletes by using the Landscape Montage Technique (LMT). In psychological consultations with athletes, they express troubles related to their physical movements. For example, when they fail to do good performance, they often say, as a retrospective remark, that they felt their body stiffened; that they could not smoothly shift their weight from one foot to the other, etc. Therefore, it is important in the psychological consultations to grasp their troubles as not only their performance-problems but also internal problems even if they only mention the former. **Methods** This study considered the oral records of conversations in the personal psychological consultations with 2 college athletes. From the records of psychological consultations, this study identified troubles in physical movements; attitudes to sport and characteristics of the Landscape Montage Technique (LMT). The aim of the creation of LMT was to identify the internal tasks that they hold. **Results** Case A (male) had troubles in motor coordination. A said about attitudes toward everyday training that he played sports without any specific purposes. The LMT of A was a picture without the connection between items. Case B (female) felt uneasiness in her physical movement. B said about attitude toward everyday training that she was doing the training just in an unindependent-minded fashion. The LMT of B didn't have a sense of perspective, and was characterized by a vague road. **Discussion** The result of this study indicated that there were similarities between the troubles in physical movements and the internal tasks. The unnatural characteristics of LMT were considered as symbol of unstable identity of athletes. Such unstable identity made their physical movement unnatural.

Mini-Orals**MO-PM22 Diet & Glucose****METABOLIC FLEXIBILITY AND ULTRA-ENDURANCE PERFORMANCE**

O'CONNOR, W., STANNARD, S., BARNES, M., CRUM, E.

Massey University

Introduction Metabolic flexibility describes the ability of a cell or tissue to easily and quickly alter the flux through specific biochemical pathways according to energetic demand and substrate availability. The antithesis, 'metabolic inflexibility' is predominantly used in reference to diseased states associated with metabolic syndrome (Storlien, Oakes, & Kelley, 2004). Metabolic flexibility of skeletal muscle is ideal for an endurance athlete enabling both optimal fat and/or carbohydrate (CHO) oxidation when required. A long term CHO-restricted training diet increases β -oxidation whilst maintaining the potential for glucose metabolism. This study was designed to introduce metabolic flexibility in an exercise context and provide a best case scenario for the application of CHO-restriction to endurance exercise performance. Methods Eight highly trained male endurance athletes ($VO_{2\text{max}} 67.0 \pm 10.4 \text{ ml/kg/min}$) ate a moderate CHO ($>5 \text{ g CHO/kg/day}$) or low CHO ($<2 \text{ g CHO/kg/day}$) diet for 4 weeks in a randomised cross-over design. Performance was measured using a self-paced time trial to complete a fixed workload equivalent to 5 hrs at 55% $VO_{2\text{peak}}$. Separately, physiological and psychological measures were collected before, during and after a 2 hr fixed intensity ride at a workload calculated to elicit 60% $VO_{2\text{peak}}$, including heart rate (HR), weight, body fat % (BF%), VO_2 , respiratory exchange ratio (RER), venous blood sample, Rating of Perceived Exertion (RPE) and profile of mood state (POMS). A carbohydrate load was allowed on both diets from the day before the performance TT. Results Performance did not differ between diets ($4:13:48 \pm 28:09$ vs $4:16:00 \pm 20:43$ for moderate CHO and low CHO respectively $p = 0.888$). Physiological measures during the 2 hr fixed intensity ride were unchanged with the exception of RER which was significantly lower in low CHO (0.88 ± 0.04 vs 0.81 ± 0.07 $p = 0.047$). POMS showed a significant difference in total mood disturbance (TMD) at 2 weeks but returned to baseline by the end. Discussion Despite the hypothesised shift in macronutrient fuels (CHO - FAT) between diets the lack of performance difference can be credited to the fundamental level of metabolic flexibility of the athletes. The athletes were able to alter their metabolism to match the physiological challenge presented for optimum performance independent of diet. An increased fat oxidation in the low CHO athletes merely decreased their need for exogenous carbohydrate. Future research into "low-carbohydrate endurance performance" should focus on dietary adaptation periods greater than 2 weeks and whether an increased metabolic flexibility is beneficial for multi-day events of varying intensity (E.g. Tour de France). Storlien, L., Oakes, N. D., & Kelley, D. E. (2004). Metabolic flexibility. Proceedings of the Nutrition Society, 63(02), 363-368.

EFFECT OF DIETARY ACID LOAD ON ACID-BASE STATUS AND EXERCISE PERFORMANCE

HIETAVALA, E.M.1, STOUT, J.R.2, SUOMINEN, H.1, PITKÄNEN, H.3, PUURTINEN, R.1, SELÄNNE, H.4, MERO, A.A.1

University of Jyväskylä

1: University of Jyväskylä (Jyväskylä, Finland), 2: University of Central Florida (Orlando, USA), 3: Honka Holding (Honkajoki, Finland), 4: LIKES Research Center (Jyväskylä, Finland) Introduction Diet composition influences acid-base status of the body (Adeva & Souto, 2011). PRAL (potential renal acid load) represents the renal net acid excretion caused by a foodstuff and it can be calculated according to a nutrient content (Remer & Manz, 1994). We studied if capillary pH and extracellular buffering capacity change after a low-PRAL (LP) and a high-PRAL diet (HP) and whether dietary acid load has an effect on performance during submaximal and maximal aerobic exercise. Methods Healthy, recreationally active women ($n=18$, age 27.6 ± 3.4 years, $BMI 21.6 \pm 2.2 \text{ kg/m}^2$) and men ($n=15$, 29.1 ± 2.7 years, $24.5 \pm 2.6 \text{ kg/m}^2$) followed a 7-day LP (PRAL $-68 \pm 23 \text{ mEq/d}$) and a 7-day HP ($54 \pm 17 \text{ mEq/d}$) in a randomized order. At the end of the diet periods the subjects performed a cycle ergometer test ($3 \times 10 \text{ min}$ at 35%, 55%, 75%, and until exhaustion at 100% of maximal oxygen consumption). Capillary blood samples were collected for pH, bicarbonate (HCO_3^-) and lactate after all workloads. Oxygen consumption (VO_2), ventilation (VE), heart rate (HR) and respiratory exchange ratio (RER) were monitored during cycling. Results Capillary pH ($P \leq 0.039$) and HCO_3^- ($P \leq 0.011$) decreased during HP in women and men. In women, pH was higher at rest ($P < 0.001$) and at 75% of $VO_{2\text{max}}$ ($P = 0.005$) and HCO_3^- was higher at rest ($P < 0.001$) and at all submaximal stages ($P \leq 0.016$) after LP compared to HP. In men, pH was higher at rest ($P = 0.038$) and at 100% of $VO_{2\text{max}}$ ($P = 0.034$) and HCO_3^- was higher at rest ($P = 0.011$) and at 55% of $VO_{2\text{max}}$ ($P = 0.035$) after LP compared to HP. In women, the maximal workload was 23% longer ($P = 0.001$) and maximal VO_2 , VE, HR, RER and lactate were higher ($P \leq 0.029$) after LP compared to HP. Discussion High dietary acid load resulted in decreased capillary pH and extracellular buffering capacity at rest in both men and women. Especially in women, pH and buffering capacity were higher during submaximal cycling after low dietary acid load, which led to improved maximal aerobic performance compared to high dietary acid load. It seems that there was a greater reliance on anaerobic metabolism after the low-PRAL diet. This might be advantageous during high-intensity exercise but detrimental during prolonged exercise. More studies are also needed to find out why dietary acid load affected performance only in women. References Adeva MM, Souto G. (2011). Diet-induced metabolic acidosis. Clin Nutr, 30(4), 416–421. ACCURACY OF CONTINUOUS GLUCOSE MONITORING DURING CONTINUOUS AND INTERVAL EXERCISE IN INDIVIDUALS WITH TYPE 1 DIABETES

MOSER, O.1,2,3,4, MADER, J.K.2, TSCHAKERT, G.1, MUELLER, A.1, GROESCHL, W.1, PIEBER, T.R.2, KOEHLER, G.2, MESSER-SCHMIDT, J.3, HOFMANN, P.1

1: KFUG (Graz, AT), 2: MUG (Graz, AT), 3: UP (Potsdam, GER), 4: UAS (Gleichenberg, AT)

Introduction Aerobic high-intensity interval exercise (HIE) and moderate continuous exercise (CON) can be safely performed with short-acting insulin reduction strategies in patients with type 1 diabetes (T1D) (Moser et al., 2015). Additional to therapy adaptations, continuous glucose monitoring (CGM) systems may serve as a tool to reduce the risk of exercise-induced hypoglycemia (Yardley et al., 2013). The aim

of the present study was to investigate the CGM accuracy for different mean intensity- and total duration-matched CON and HIIE in TID. Methods 7 male individuals with TID performed CON and HIIE at 5% below (II) and above (III) the first lactate turn point (LTP1) and 5% below the second lactate turn point (LTP2) (III) on a cycle ergometer (Hofmann et al., 2010). Glucose concentration was measured in the capillary blood (BG) and via a CGM (Guardian® REAL-Time CGM, Medtronic, USA) system within the subcutaneous abdominal tissue. Comparison of BG vs. CGM was performed by using multiple t-tests, Bland-Altman method and Pearson correlation. Additionally, data were analyzed with Clarke Error Grid analyses. Values in zones A and B were deemed clinically acceptable. Results No significant differences were found in comparison of BG and CGM over time ($p>0.05$). In CON the following bias and levels of agreement for I, II and III were found: 0.85 (-3.44, 5.15), -0.45 (-3.95, 3.05), -0.31 (-8.83, 8.20) similar to HIIE: 1.17 (-2.06, 4.40), 0.11 (-5.79, 6.01), 1.48 (-2.60, 5.57). Correlations between BG and CGM were found during CON ($p<0.01$) for I: $r=0.93$, II: $r=0.92$, III: $r=0.96$ and HIIE ($p<0.01$) for I: $r=0.74$, II: $r=0.99$, III: $r=0.91$. During CON for intensity I, 96% of values were in zones A and B (52% and 44%), for II 100% (79% and 21%) and for III 78% (30% and 48%). During HIIE, zones A and B were reached for intensity I by 100% (63% and 37%), for II by 93% (48% and 45%) and for III by 93% (55% and 38%). Discussion CGM values estimated BG with acceptable accuracy. Even so, in comparison of both exercise types, CGM was clinically accurate except during CON at III. Using CGM along with therapy adaption may be a practical tool to avoid exercise-induced hypoglycemia in patients with TID. INHIBITION OF GLYCOLYSIS AS A TOOL TO ENHANCE PERFORMANCE? - EFFECTS OF LEG-INDUCED HIGH BLOOD LACTATE ON SUBSEQUENT DYNAMIC AND STATIC ANAEROBIC UPPER BODY EXERCISE

BIRNBAUMER, P., MÜLLER, A., TSCHAKERT, G., HOFMANN, P.

Institute of Sports Science, Exercise Physiology & Training Research Group University of Graz, Graz, Austria

Objectives Studies have shown that high intensity exercise has an effect on subsequent lower body exercise by inhibiting glycolysis and enforcing a higher oxidative metabolism (1,2). The aim of this study was to examine the effect of a high blood lactate concentration induced by high intensity leg exercise on subsequent dynamic pull ups and static hanging. Methods Nine trained sport students (age: 25.1 \pm 1.9 yr; BMI: 21.7 \pm 1.4 kgm $^{-2}$) participated in the dynamic (d) and static (s) trial, with (26.6 \pm 2 sec all out shuttle run) and without pre load (PRE) on four different days. Pull ups and static hanging (90° elbow flexion) were performed in randomized order on a horizontal bar with legs placed on a box. Each testing was preceded by a 15 min standardized warm up. Time between warm up and testing was 14 min. During testing heart rate (HR) and gas exchange data (VO₂, VCO₂, VE) were monitored and lactate levels (La) were measured at specific time points. Results Anaerobic exercise without PRE increased La from 1.24 \pm 0.4 to 6.4 \pm 1.39 (d) and 1.12 \pm 0.4 to 5.11 \pm 1.13 mmol/l (s). In PRE La increased from 9.28 \pm 1.98 to 10.89 \pm 2.13 (d) and 9.04 \pm 1.69 to 9.83 \pm 1.39 mmol/l (s). Net La accumulation was sign. reduced in PRE conditions by 75.5% (d) and 80% (s). Performance increased sign. by 1 rep (4%) in d and remained unchanged in s (106.7 \pm 36.5 / 106.2 \pm 31.14 sec). A sign. increase in net VO₂ (d: 50%; s: 30%), VE (d: 34%; s: 36%) and VCO₂ (d: 26%) but was reduced by 30% in s. Net respiratory exchange ratio (RER) was significantly lower during work and recovery after PRE in dynamic and static testing. Conclusions A high blood La induced by anaerobic leg exercise, inhibits glycolysis and forces higher oxidative metabolism in subsequent anaerobic dynamic and static upper body exercise. A higher amount of oxidative metabolism during strength endurance exercise leads to a higher performance as can be seen in the dynamic version. This concept may be applied in sports such as sport climbing but has to be evaluated in more detail. References 1) Bogdanis, G. C., Nevill, M. E. & Lakomy, H. K. (1994). GLUCOSE-FRUCTOSE BEVERAGES DO NOT ALTER THE EFFECTS OF TRAINING ON LACTATE METABOLISM

ROSSET, R., EGLI, L., CROS, J., SCHNEITER, P., TAPPY, L., LECOULTRE, V.

University of Lausanne

Introduction It is generally accepted that lactate is produced by skeletal muscle during exercise, and is either used in adjacent muscle fibers (lactate shuttle) or recycled to glucose in the liver. We have shown that ingestion of fructose-containing drinks stimulates lactate production and release from the liver during exercise, and that fructose-derived lactate is subsequently used as an energy substrate by muscle. The regulation of this liver to muscle fructose-lactate shuttle remains unknown. In this study, we assessed whether consumption of fructose-containing beverages alters the effects of training on fructose and lactate metabolism. Methods Two groups of eight sedentary male subjects were endurance-trained for three weeks while ingesting 489 mL/h of either a 9.8%-glucose 6.2%-fructose beverage (GLUFRU) or water (C) during exercise training sessions. An incremental test to exhaustion and a metabolic test were performed before and after the interventions to assess training adaptations and substrate use during endurance-type exercise. Indirect calorimetry, [¹³C]lactate and [^{1,6-2H₂}]glucose were used to calculate plasma lactate appearance, clearance and oxidation and glucose kinetics. Results Anthropometrics and performance parameters were similar in both groups at baseline. Plasma glucose concentrations (+1 \pm 3 vs. +3 \pm 3 % vs. baseline values), glucose rate of appearance (+3 \pm 7 vs. +2 \pm 3 %) and metabolic clearance (+6 \pm 8 vs. +1 \pm 5 %) remained stable after both GLUFRU and C training (all p=n.s.). Overall, lactate concentrations were decreased after intervention in both GLUFRU and C, but not differently between groups (-10 \pm 5 vs. -20 \pm 4 %; p<0.01 vs. baseline, p=n.s. between GLUFRU and C), as a result of an increased lactate metabolic clearance (+26.5 \pm 11.4 vs. +17.5 \pm 10.2 mL·min $^{-1}$; p=0.01 vs. baseline, p=0.56 between GLUFRU and C). Lactate appearance (+10 \pm 6 vs. -4 \pm 9 %) and oxidation (+9 \pm 6 vs. -6 \pm 9 %) remained unchanged across time and conditions (all p=n.s.). Maximal oxygen consumption (+287 \pm 53 vs. +249 \pm 104 mL·min $^{-1}$) and power eliciting lactate threshold (+25 \pm 5 vs. +25 \pm 8 W) were similarly increased in GLUFRU and C (both p<0.01 vs. baseline, p=n.s. between GLUFRU and C). Discussion These data corroborate our earlier observation that fructose is converted into lactate by the liver and subsequently oxidized during exercise. Endurance training did not alter liver lactate release, but increased lactate metabolic clearance. The effects of endurance training were not differently altered by the consumption of fructose during training sessions, however. Contact Robin.Rosset@unil.ch

EXERCISE TRAINING ATTENUATES AGE-INDUCED CHANGES IN MITOCHONDRIAL FUNCTION AND INSULIN RESISTANCE IN RAT SKELETAL MUSCLES

KWAK, H.B.¹, CHO, H.S.², SHIN, M.S.², KIM, C.J.², PARK, D.H.¹, NO, M.H.¹

¹:Inha University (Incheon, South Korea), ²: Kyung Hee University (Seoul, South Korea)

Introduction Aging is characterized by a progressive loss of muscle mass and muscle strength called 'sarcopenia'. Age-related muscle atrophy is due to loss of muscle fibers associated with mitochondrial dysfunction. Accumulating evidence shows that impairment in skeletal muscle mitochondria with aging is thought to play a primary role in insulin resistance (Petersen et al., 2015; Toledo and Goodpaster, 2013). The development of insulin resistance, particularly in skeletal muscle, is closely associated with type II diabetes. The purpose of this study was to identify the role of exercise in age-induced sarcopenia, mitochondrial dysfunction, and insulin resistance in rat skeletal muscles. Methods Four and 20 month old Fischer-344 rats were randomly assigned to young sedentary (YS), young exercise (YE), old sedentary (OS), or old exercise (OE) groups (N=10 rats/group). Exercise training groups ran on a treadmill at 15 m/min (young) or 10 m/min (old), 45 min/day, 5 day/week for 8 weeks. The skeletal muscles such as soleus (SOL, Type I) and white gastrocnemius (WG, Type IIb) were permeabilized by saropin for determination of mitochondrial respiratory capacity, Ca²⁺ retention capacity, and mitochondrial H₂O₂ emission. Oral glucose tolerance test (OGTT, 2 g glucose/kg) was performed to measure blood glucose levels. Results Exercise training attenuated age-induced decrease in only gastrocnemius (Type II) mass. Insulin resistance by oral glucose tolerance test was elevated in OS rats. However, exercise training preserved whole body insulin sensitivity in OE rats ($P<0.05$). The mitochondrial respiratory capacity and Ca²⁺ retention capacity were decreased by aging and protected by exercise training in both SOL and WG ($P<0.05$). In addition, exercise attenuated age-induced mitochondrial H₂O₂ emitting potential in both SOL and WG ($P<0.05$). Discussion These data demonstrate that regular exercise training prevents the impairment of mitochondrial function in skeletal muscles as well as sarcopenia induced by aging, supporting the concept that the exercise regulation of mitochondrial dysfunction with aging is a primary factor protecting against aging-induced sarcopenia and insulin resistance in skeletal muscle. PRE-EXERCISE INGESTION OF CARBOHYDRATE DOES NOT INDUCE HYPOGLYCEMIA DURING CYCLING EXERCISE IN JAPANESE MEN

KONDO, S.I, TANISAWA, K.2, ITO, T.1, SUZUKI, K.2, HIGUCHI, M.2

^{1,2}:Waseda University

Introduction A number of studies have demonstrated that carbohydrate (CHO) ingestion 30 min before exercise induces hyperglycemia and hyperinsulinemia, which is followed by a rapid decrease in blood glucose and hypoglycemia early in exercise. However, these studies were mainly performed with Caucasian subjects, and it has never been investigated in Japanese subjects. Because Japanese individuals have lower insulin secretory capacity compared with Caucasian, CHO ingestion before cycling exercise may not induce hypoglycemia in them. Furthermore, it remains unknown whether a fasting status before ingestion of CHO influences on the occurrence of hypoglycaemia during exercise. Therefore, the purpose of this study was to investigate whether CHO ingestion before cycling exercise induces hypoglycaemia in Japanese men regardless of a fasting status. Methods Eight males (age 20.6±1.1 yr) completed four trials. After a 12-h overnight fast (12h) or 3-h fast (3h), subjects ingested either 150 g of glucose in 500 mL of water (Glu), or 500 mL of placebo (Pla), 30 min before exercise. The exercise trial consisted of 60 min of submaximal cycling exercise at 75% VO_{2max}, immediately followed by a performance trial at 90% VO_{2max} until exhaustion. Blood samples were obtained at 30 min before exercise (before drinking Glu/Pla), at the start of exercise, 15, 30, and 60 min during exercise and after a performance trial for determination of plasma glucose, serum insulin levels. We considered blood glucose levels below 60mg/dL as hypoglycemia. Results At the start of exercise, the plasma glucose and serum insulin were significantly higher in the 12h+Glu and 3h+Glu trials compared with 12h+Pla and 3h+Pla trials (glucose, 122±17, 124±27 vs. 79±11, 79±8 mg/dL, $p<0.05$; insulin, 38.4±12, 39.0±11 vs. 5.1±5, 4.4±9 μU/mL, $p<0.05$). Although the plasma glucose and serum insulin rapidly decreased at 15min of exercise compared with the start of exercise in the 12h+Glu and 3h+Glu trials, the plasma glucose remained above 60 mg/dL (82±12 and 69±15 mg/dL). In the performance trial, there were no differences in the exercise times to exhaustion between the four trials. Discussion The present study suggests that CHO ingestion before cycling exercise does not induce hypoglycemia in Japanese men regardless of fasting status. The previous study reported that Japanese men had lower insulin secretory capacity than US white men (Vasudha A, 2015). Thus, hypoglycemia might not occur during cycling exercise in Japanese men due to the differences in insulin secretory capacity by ethnicity. References Vasudha Ahuja et al. (2015). EFFICACY OF INGESTION OF A NOVEL INSULINOTROPIC PROTEIN HYDROLYSATE COMBINED WITH CARBOHYDRATE ON RECOVERY OF SKELETAL MUSCLE GLYCogen AND SUBSEQUENT ENDURANCE EXERCISE CAPACITY

COGAN, K., EVANS, M., MELVIN, A., IULIANO, E., DEVITO, G., SUSTA, D., EGAN, B.

University College Dublin

Introduction Supplementing sub-optimal carbohydrate (CHO) refuelling strategies with either intact, or hydrolysed protein sources may compensate for inadequate CHO intake, and in certain conditions, augment glycogen resynthesis following short-term recovery (≤ 6 hours). Addition of an insulinotropic protein source may also positively influence protein turnover following prolonged endurance exercise and facilitate recovery. Methods The effect of CHO, or CHO supplemented with either casein (CHO-C) or an insulinotropic casein hydrolysate (CHO-H) on recovery of skeletal muscle glycogen and markers of protein synthesis following prolonged endurance exercise were determined in trained male cyclists (n=11, mean±SEM age 28.8±2.3y; body mass (BM) 75.0±2.3 kg; VO_{2peak} 61.3±1.6ml.kg⁻¹.min⁻¹). Participants cycled for 2h at 70% V_{Opeak} followed by a 4h recovery period. Following endurance exercise, participants consumed an isoenergetic drink at +0h and +2h of recovery containing (i) CHO (1.2g.kg⁻¹ BM), (ii) CHO-C or (iii) CHO-H (1.04 and 0.16g.kg⁻¹BM respectively). Trials were conducted in random order in a double-blind manner. Following recovery, participants then completed a timed cycle to exhaustion at 70% V_{Opeak}. Muscle biopsies from the vastus lateralis were taken prior to commencing each trial, and at +0h and +4h of recovery for determination of skeletal muscle glycogen, and intracellular markers of insulin signalling and protein synthesis. Serum and plasma samples were collected every 30 min. Results Despite an elevated peak in insulin following CHO-H ingestion, there was no significant difference in skeletal muscle glycogen resynthesis at +4hr between any trial ($p=0.256$). Paradoxically, an elevated insulin response in CHO-H coincided with higher plasma glucose throughout the same time period. There was no significant difference for timed cycle to exhaustion between trials (71.0±7.9, 63.9±6.3 and 63.2±5.1mins for CHO, CHO-C and CHO-H respectively) ($p=0.652$). Discussion

Glycogen resynthesis during recovery from intense exercise after ingestion of sub-optimal CHO ingestion combined with an insulinotropic protein hydrolysate, is not improved by the augmented insulin response. Furthermore, elevated insulin secretion may paradoxically increase plasma glucose concentrations during recovery. Work is currently on-going to elucidate any potential differential regulation of intramuscular insulin signalling and protein synthesis in responses to the various recovery drinks. karl.cogan@ucdconnect.ie This study was supported by funding from Food for Health Ireland

THE EFFECTS OF 3 WEEKS OF UPHILL AND DOWNSHILL WALKING ON LIPIDS AND GLUCOSE METABOLISM IN PRE-DIABETIC MEN

PHILIPPE, M., GATTERER, H., EDER, E.M., DZIEN, A., SOMAVILLA, M., MELMER, A., EBENBICHLER, C., BURTSCHER, M.

University of Innsbruck

Introduction It is still a matter of debate whether lipids and glucose metabolism are differently affected by regular concentric (e.g. uphill walking) and eccentric (e.g. downhill walking) endurance exercise (Drexel et al., 2008, Marcus et al., 2009). The aim of this study was to investigate in a real world setting the effects of 3 weeks of uphill and downhill walking on lipids and glucose metabolism in pre-diabetic men. Methods 16 pre-diabetic men (age: 56.9 ± 5.1 years; BMI: 28.1 ± 2.3 kg/m²) performed 9 supervised and monitored uphill (N=8) or downhill (N=8) walking sessions within 3 weeks. Markers of the glucose metabolism and blood lipids were measured before and after the training period. Results After uphill walking (pretest vs. posttest) glucose tolerance (area under the curve: 322.7 ± 69.5 vs. 279.5 ± 47.8 mg/dl; P=0.05; ES:large) triglycerides (165.8 ± 90.8 vs. 117.0 ± 45.3 mg/dl; P=0.036; ES:large), HDL-C (45.4 ± 6.2 vs. 53.2 ± 10.8 mg/dl; P=0.05; ES:large) and total cholesterol/HDL-C ratio (4.6 ± 0.8 vs. 4.0 ± 0.8 ; P=0.012; ES:large) improved significantly. No significant metabolic adaptations were measured after downhill walking. When adjusted for energy expenditure uphill and downhill walking had equal effects on all metabolic parameters. The magnitude of the baseline impairments of the glucose tolerance correlated significantly with the extent of change in the uphill walking group ($R=-0.728$; P=0.041) and in the downhill walking group ($R=-0.730$; P=0.040). Discussion Our findings do not confirm prior results that downhill walking is equally effective in improving glucose tolerance when compared to uphill walking (Drexel et al., 2008). In contrast to downhill walking 3 weeks of uphill walking effectively improved glucose tolerance and most of the measured lipid markers in pre-diabetic men. However, when considering the related energy expenditure both types of walking seem to have equal effects. Moreover persons with more pronounced impairments of the glucose metabolism benefited from both training regimens. THE EFFECT OF CHIOS MASTIC GUM EXERT AS A FACTOR RELATED TO LIPID METABOLISM, GLUCOSE METABOLISM AND BODY COMPOSITION

FUKAZAWA, T.1, SMYRNIODIS, I.2, KONISHI, M.1, KIM, H.1, NISHIMAKI, M.1, TABATA, H.1, XIANG, M.1, SAKAMOTO, S.1

1:Waseda University (Saitama, Japan) 2:The Chios Mastic Growers Association/Chios, Greece

Introduction "Chios mastic gum (Chios mastihal)" is the air-dried, resinous exudation of the mastic tree. Its scientific name is known as Pistacia lentiscus var. Chia, and originates from the Island of Chios in Greece. It is a famous pharmaceutical plant being the first natural chewing gum since the Hippocratic period in ancient Greece. There are many studies that have found therapeutic effects of Pistacia lentiscus var on various ailments and Diseases (Petersen et al., 2011). This study aims at exploring ways in introducing Chios mastic gum to Japan with focus on its therapeutic effect on lipid metabolism, glucose metabolism and body composition. Methods We studied the results of our experiment on 12 healthy Japanese male of over 40 years old. Group-C (n-6) received placebo powder 5g/day. Group-M (n-6) received Chios mastic powder 5g/day. The period of the experiment lasted six months for both groups. We carried out the following blood test and physical measurement three times: 1. before starting the experiment, 2. 3 months after having started the experiment and 3. 6 months after having started the experiment. Blood test: Items concerning lipid metabolism consists of total cholesterol, LDL-cholesterol, HDL-cholesterol, triglycerides and L-CAT. Items concerning hepatic function consists of SGOT, SGPT and gamma-GTP. Group of Glucose Metabolism consists of insulin and glucose. We measured body composition including BMI, waist circumference, percentage of body fat and muscle mass. Results Comparing the differences between the two Groups, we have found that : The 2nd and 3rd blood test compared to the 1st, there was not significant difference about total cholesterol, HDL-cholesterol, triglycerides, L-CAT, SGOT, SGPT, gamma-GTP and glucose. However, Group-M exhibited significant reduction of LDL-cholesterol and insulin in the 3rd blood-test comparing it with the 1st : LDL (p<0.05) , insulin(p<0.08). Both groups indicated no significant difference on Body Composition in 2nd and 3rd measurement comparing them with the 1st. Conclusion This study suggests that Chios mastic gum extract has a potential to decrease LDL-cholesterol and insulin. And this study will also propose culinary ways of Chios mastic gum so that it will be introduced into Japanese society as an appropriate food for Japanese people. DOES CHRONIC USE OF CAFFEINE REDUCE ITS ACUTE ERGOGENIC EFFECTS DURING HIGH INTENSITY INTERVAL TRAINING?

SALAM, H., HOPKER, J., MARCORA, S.

University of Kent

DOES CHRONIC USE OF CAFFEINE REDUCE ITS ACUTE ERGOGENIC EFFECTS DURING HIGH INTENSITY INTERVAL TRAINING? Based on extensive research showing positive effects on performance (Spriet, 2014), many athletes use caffeine before and during competitions (Coso et

al, 2011). However, the use of caffeine during training is not well understood. Therefore, the first aim of this study was to test the hypothesis that caffeine acutely increases power output, heart rate (HR), and blood lactate during high intensity interval training (HIIT). The second aim was to test the hypothesis that chronic use of caffeine reduce its hypothesised acute ergogenic effects during HIIT (tolerance). Methods Twenty recreational male endurance athletes (age 33±9 years; VO_{2max} 55.3 ± 8.9 ml/kg/min) took part in the study. Each participant completed 7 test visits in the laboratory. During the first was an incremental test, and familiarized. A second familiarization occurred during visit 2. During visit 3 and 4, the acute ergogenic effects of caffeine (3 mg·kg⁻¹ body weight) ingested 1 hour before HIIT were assessed using a placebo-controlled. HIIT consisted of 4 bouts (RPE 16, 17, 18, and 19) of 4 min each. Participants were randomly allocated to two groups. One group took caffeine 3 times a week 1 hour before 3 of their regular training sessions. The other group took placebo (Dextrose). After 4 weeks of such chronic supplementation, all participants performed a follow-up assessment of VO_{2max} (visit 5) and the acute effects of caffeine (visits 6 and 7). Relevant main effects and interactions on VO_{2max} and power output/HR/blood lactate during HIIT were analysed by mixed analyses of variance (ANOVA). Results No significant changes in VO_{2max} were observed in either groups after 4 weeks of training. As hypothesised, caffeine acutely increased power output, HR and blood lactate during HIIT at both the baseline and follow-up assessments. There were no significant interactions and main effects of time suggesting the development of tolerance to these acute ergogenic effects of caffeine during HIIT after 4 weeks of chronic supplementation. Discussion Caffeine ingestion one hour prior to HIIT acutely increases power output, HR and blood lactate for the same RPE. Frequent use of caffeine before training (3 times a week for 4 weeks) does not reduce these acute ergogenic effects of caffeine during HIIT. This observation argues against the development of tolerance and suggests that pre-training caffeine ingestion is a useful strategy to increase training intensity. Whether this increase in training intensity leads to greater gains in performance needs to be investigated in future studies with more controlled training programs and longer follow up periods. EFFECTS OF CAFFEINE ON CENTRAL AND PERIPHERAL FATIGUE DURING ANAEROBIC EXERCISE PERFORMANCE – A SYSTEMATIC REVIEW

MESQUITA, R., KYRÖLÄINEN, H., AVELA, J.

University of Jyväskylä

Introduction: It has been shown that caffeine ingestion delays fatigue and it seems to be ergogenic during high-intensity exercise. Caffeine may attenuate the loss of force-generating capacity induced by anaerobic exercise, but its mechanisms of action at the various levels of the motor pathway are not fully understood yet. The aim of this review was to systematically evaluate the existing literature about the effects of caffeine on central and peripheral fatigue during anaerobic exercise performance. Methods: Studies were identified by searching from the earliest record until February 2016 (week 1) using the MEDLINE (Ovid), PubMed and Web of Science. The search terms used were "caffeine" and "central fatigue" or "peripheral fatigue" or "muscle fatigue". Randomized controlled trials published in peer-reviewed journals were considered for inclusion. Intake of caffeine and a measure of central and/or peripheral fatigue during anaerobic exercise were required in each study. Results and discussion: Nine studies with a total of 103 participants were included. Electromyographic (EMG) activity from 7 studies showed no effect of caffeine on muscle activation variables during submaximal isometric contractions and in anaerobic cycling exercise. Two of these studies also used intramuscular EMG and found no differences on firing rates between conditions. Only one study (Plaskett & Cafarelli, 2001) found a significantly higher EMG activity in the caffeine condition at the end of the protocol, possibly due to an improved motor unit synchronization. Effects of caffeine on the enhancement of calcium mobilization is still controversial. Fredholm et al (1999) showed that the doses required to achieve this effect would be toxic to humans. Nevertheless, one study showed an attenuated decrease of the twitch amplitude (Meyers & Cafarelli, 2005) and another one an offset of the decline in low-frequency tetanic force (Tarnopolsky and Cupido, 2000) and, therefore, this hypothesis should not be dismissed. Caffeine's effects on central excitability are clear, potentiating motor evoked potentials before task failure. This effect has been convincingly attributed to the mechanisms of adenosine receptor antagonism. However, it seems that this central effect is not associated with enhanced maximal voluntary activation (Kalmar and Cafarelli, 2004; Kalmar and Cafarelli, 2006), demonstrating that voluntary activation is not limited by central excitability. THE EFFECTS OF CAFFEINE ON PHYSIOLOGICAL AND METABOLIC RESPONSES AND ON EXERCISE PERFORMANCE DURING A SIMULATED TREADMILL SOCCER-GAME PROTOCOL

HADJCHARALAMBOUS, M., APOSTOLIDIS, A., MOUGIOS, V., SMILIOS, I., RODOSTHENOUS, J., KYPRIANIDES, P., KARAPETYAN, L., KLEANTHOUS, M., ANTONIOU, M., FRAGKOUS, M., OIKONOMIDES, K.

University of Nicosia

Introduction In several previous studies, the effects of caffeine ingestion on exercise performance, blood metabolites and physiological responses were equivocal, possibly due to different experimental protocols and caffeine dosage employed. However, no studies have examined the influence of caffeine on physiological and metabolic responses and on performance in exercise simulating a soccer game in a well-controlled laboratory environment. Therefore, the aim of the present study was to examine the effects of caffeine ingestion on metabolic and physiological responses and on exercise performance during a protocol simulating a soccer game on treadmill in well-trained soccer players. Methods Twenty well-trained male soccer-players (age, 22 ± 4; weight, 74.2 ± 7.7 kg; height, 1.80 ± 0.05 m, body fat, 11.5 ± 3.7 %, VO_{2max}, 60.8 ± 4.3 ml/min/kg) underwent two experimental trials after ingestion of either 6 mg/kg caffeine or placebo, in a controlled laboratory environment, using a simulated soccer game protocol on treadmill. Plasma glucose, lactate, free fatty acids (FFA), glycerol and epinephrine concentrations, heart rate (HR), countermovement jumps (CMJ), reaction time, rating of perceived exertion (RPE), arterial blood pressure (BP) and soccer-specific time to fatigue were evaluated. Results Plasma glucose, lactate, FFA, glycerol and epinephrine concentrations, HR, CMJ, BP and time to fatigue were significantly higher, while RPE was significantly lower with caffeine compared with placebo ($p<0.05$). Reaction time did not differ between the trials ($p>0.05$). Discussion Caffeine was found to enhance CMJ and soccer-specific time to fatigue; increase the concentration of blood metabolites, HR and BP; and reduce RPE during a simulated soccer-specific treadmill protocol. These results may suggest that there is a direct stimulant action of caffeine on metabolic and physiological responses and/or on central and peripheral (e.g., neuromuscular junction) nervous system contributing to improving high-intensity endurance performance and muscle explosiveness, respectively.

INFLUENCE OF CAFFEIN ON MUSCLE FORCE: PERCEPTION OF SIDE EFFECTS

THALLER, S., HÖHER, P.

University of Graz

Introduction The placebo effect plays an important role whenever the effect of an intervention is investigated. When measuring the muscle force, the result depends crucially on the perception of the subject (Beedie et al. 2006). To avoid such effects, normally a double blind study is chosen so that neither the subject nor the investigator knows whether the placebo or the verum was applied. If the verum has side effects, the administration of active placebos, i.e., placebos with similar side effects is suggested (Thomson 1982; Pollo et al. 2011). When investigating the effects of drinking coffee on the muscle force, the subjects could get some information about being in the placebo or the verum group by the well-known side effects such as increased heart rate or increased urge to urinate. We investigated the expectancy of the subjects before and after the force measurement. **Method** The isometric force of 17 male subjects (26.7 ± 4.8 yrs, 1.8 ± 0.1 m, 76.1 ± 6.6 kg) was measured in a double-blind, crossover, randomized study under the influence of caffeine containing coffee (CAF) and decaffeinated coffee (DECAF). Before and after the measurements, the subjects were asked if they think they were in the placebo or the verum group. Results 5 out of 17 subjects (29.4 %) guessed both the CAF and the DECAF group correctly before the force measurements and 8 of 17 (47.1 %) after the measurements. In 22 of 34 trials (64.7 %) the placebo group was chosen. Compared to a percentage of 50 % this was a significant difference. The subjects who decided correctly did not show a significant increase in muscle force. **Discussion** The percentage of correct answers did not differ significantly from the 50% level when there is no information about the group membership. However, assuming that the knowledge of some side effects should increase this level to at least 55% would lead to a significant difference between the reported perception and this level. That suggests that in studies investigating the influence of drinking coffee the knowledge of side effects does not play a role. A conditioning effect that evokes side effects just by drinking inert placebo liquid would lead to wrong perceptions of having got CAF instead of DECAF. The observed tendency to DECAF could be due to the lack of perceived side effects and the general feeling of being deceived in the study. References Beedie, C. J., Stuart, E. M., Coleman, D. DOES CAFFINE CONTAINING COFFEE CHANGE THE SHAPE OF THE FORCE-VELOCITY RELATION IN THE MUSCLE?

HÖHER, P., THALLER, S.

Institute of Sports Science

Does Caffeine Containing Coffee Change the Shape of the Force-Velocity Relation in the Muscle? Institute of Sports Science, University of Graz, Austria **Introduction** The beneficial effects of caffeine on endurance for long-time muscle activation have already been stated (Warren et al., 2010). For short-time activation, however, the knowledge is comparatively rare. Therefore, the purpose of our study was to investigate the shape of the force-velocity relation (FV) of the muscle in short-time movements after administering caffeine containing coffee. **Methods** In a double-blind, crossover, randomized, counterbalanced study design, 17 male subjects (26.71 ± 4.79 yr, 1.80 ± 0.07 m, 76.09 ± 6.57 kg) performed several leg extension movements on an inclined leg press with maximum voluntary contraction. The trials were conducted with preceding administration of caffeine containing coffee (CAF) (4.83 ± 0.17 mg/kg body weight) and decaffeinated coffee (DECAF). 60 minutes prior to exercise each subject got CAF or DECAF. Subsequently, they performed dynamic leg extension movements with different loads and isometric movements with fixed skid (120° angle) of the leg press. In accordance with the washout phase, 1 week, the subjects ingested the opposite substance and passed the test protocol a second time. By using nonlinear parameter identification, Hill's constants (a, b, c) - for getting FV of the muscle - were determined from a model of the movements (Siebert et al., 2007). A paired t-test was used to calculate the p-value. **Results** In the CAF compared to the DECAF conditions a significant change ($p = 0.04$) in the curvature of the FV curves and in Hills's constant b ($p = 0.04$) could be observed. The maximum isometric force in the muscle ($p = 0.06$), the maximum power output ($p = 0.42$), the maximum velocity ($p = 0.44$) and the maximum isometric force measured outside of the muscle ($p = 0.07$) didn't show a significant increase or decrease. However, all subjects which were ≤ 25 yr (23.0 ± 2.12 yr) ($n = 9$), had a significant increase of the maximum isometric force in the muscle ($p = 0.02$). The daily mean caffeine intake of these subjects was reported to be 0.7 cups/day, half as much as the older ones ($n = 8$) (30.88 ± 2.93 yr) drank (1.4 cups/day). **Discussion** The measurements show that administering caffeine containing coffee leads to an increase of the curvature of the force-velocity relation in the muscle. This curvature is related to the efficiency, comparing the consumed chemical energy to the mechanical energy output. There is a disparity in the response of the muscle after caffeine intake of more and less habituated coffee drinker. The effect of expectancy when drinking coffee is published in another abstract. THE VALUE OF AN ACUTE DOSE OF ROOIBOS IN HEALTHY MALES: AN EXERCISE-INDUCED OXIDATIVE STRESS SCENARIO

MARNEWICK, J.L.1,2, DAVIES, S.E.H.3, WEST, S.3, TALIEP, S.3, RAUTENBACH, F.1, VAN DER WESTHUIZEN, L.2, VENTER, I.4, BESTER, D.J.1

Cape Peninsula University of Technology

Introduction The unique South African herbal tea, rooibos was previously shown to modulate the redox status in humans (Marnewick et al., 2011). The current study aimed to profile a number of oxidative stress biomarkers, as well as exercise performance indicators after two exercise regimes to assess the efficacy of an acute dose of rooibos in altering these biomarkers. **Methods** Forty healthy adult male volunteers were randomised in a single blinded, cross-over placebo controlled study. They consumed a standardised breakfast snack and three capsules of a rooibos extract or placebo before undergoing a muscular isokinetic strength and cardiovascular endurance fatiguing trial. Muscle fatigue was induced using elbow extension/flexion test on the Biomedex (15 repeats, 5 sets) while the cardiovascular endurance stress was induced via the multistage treadmill exercise test (Bruce protocol). Blood samples were taken at 5 time points during these regimes. Participants recorded 3 non-consecutive day food records before each intervention. None were taking any dietary supplements. **Results** Isokinetic strength significantly increased as represented by the total work ($P=0.019$), average power ($P=0.021$) and average peak torque ($P=0.01$) during the 2nd extension when comparing rooibos with placebo. No significant differences were shown for the other repetitions. The multistage maximal exercise test showed no significant differences in exercise time to exhaustion or maximum heart rate at termination between the rooibos and placebo. When considering the blood oxidative stress biomarkers, rooibos significantly

decreased the levels of conjugated dienes at all 5 time points when comparing with the placebo. Rooibos also significantly enhanced ($P<0.05$) the antioxidant capacity (ORAC) (4-5%) at these 5 time points. Discussion Results show an acute dose of rooibos to be protective against exercise-induced oxidative stress, by minimising the oxidative damage to that of baseline levels possibly due to an enhanced defence system. Although rooibos provided some cellular protection, it is unclear if it is related to the improved exercise markers, as previous studies reported modifications in blood oxidative stress did not consistently correspond with exercise-induced indicators of endurance and strength (Pereira-Panza et al., 2015; Goldfarb et al., 2011). Critical analysis is needed. References Goldfarb AH, Garten RS, Cho C, Chee PD, Chambers LA. (2011). Med Sci Sport Exerc, 43, 501-508. QUANTIFICATION OF NUTRITIONAL INTAKE DURING A CONGESTED FIXTURE PERIOD IN PLAYERS FROM THE ENGLISH PREMIER LEAGUE

ANDERSON, L., ORME, P., NAUGHTON, R., CLOSE, G.L., LOUIS, J., MORGANS, R., DRUST, B., MORTON, J.P.

Liverpool John Moores University

1: Liverpool Football Club (Liverpool, UK), 2: LJMU (Liverpool, UK) Introduction Muscle glycogen is the primary energy source during soccer match play (Krustrup et al. 2006). In times of fixture congestion (i.e. consecutive matches every 2-3 days), it has therefore been suggested that soccer players consume high daily carbohydrate (CHO) intake (>6 g/kg) in an attempt to promote muscle glycogen re-synthesis and match day physical performance (Anderson et al. 2015). The aim of this study was to therefore quantify daily energy intake and macronutrient composition in English Premier League (EPL) soccer players undergoing a period of fixture congestion. Methods Six professional EPL (from one team) soccer players (mean \pm SD; age: 27 \pm 3 years, body mass: 80.5 \pm 8.7 kg, height: 180 \pm 7 cm, body fat: 11.9 \pm 1.2%, lean body mass, LBM: 65.0 \pm 6.7 kg) completed daily food diaries alongside the remote food photographic method (RFPM) over a 7-day period consisting of 2 competitive games (Day 2 and 5) and 5 training sessions (Day 1, 3, 4, 6 and 7). Data were analysed for total daily energy, CHO, protein and fat intake using dietary analysis software (Nutritics Ltd, Ireland). Results Energy intake was greater on ($P<0.05$) match days (MD) (3789 \pm 577 kcal and 61.1 \pm 12.5 kcal/kg LBM) compared with training days (TD) (2948 \pm 686 kcal and 45.2 \pm 12.2 kcal/kg LBM, respectively). Similarly, CHO intake was also greater ($P<0.05$) on MD (6.4 \pm 2.2 g/kg) compared with TD (4.2 \pm 1.6 g/kg). In contrast, neither protein (2.7 \pm 0.4 g/kg v 2.5 \pm 0.7 g/kg) nor fat intake (1.5 \pm 0.6 g/kg v 1.2 \pm 0.2 g/kg) was different between MD and TD, respectively. CHO intake during matches (35.8 \pm 21.5 g/min) was also different ($P<0.05$) from that consumed during training sessions (5.5 \pm 10.3 g/min). Discussion In accordance with current sports nutrition guidelines (Burke et al. 2011), we conclude elite soccer players consume apparently adequate energy and CHO intake for the typical loads observed on MD versus TD. However, on the basis of a congested fixture period (i.e. 2 days between games), we suggest players should consume higher daily energy and CHO intakes (similar to those reported on MD) on TD between matches so as to promote glycogen re-synthesis in recovery from match play and prepare for the subsequent game. OBJECTIVELY MEASURED STRIDE LENGTH UNDER FREE-LIVING CONDITION ASSOCIATES WITH WHOLE BODY MUSCLE MASS IN OLDER ADULTS

AYABE, M.1, ISHIZAKI, S.2, KUMAHARA, H.3, INUKAI, Y.1

1. Okayama Prefectural University (Okayama, Japan) 2. Shibaura Institute of Technology (Saitama, Japan) 3. Nakamura Gakuen University (Fukuoka, Japan)

[BACKGROUND & OBJECTIVE] Although the walking related parameters, such as walking speed, the time spent in walking, the walking distance, positively associates with the health outcomes, a little is known about the significance of the stride length under free-living condition. Recently we have developed a novel approach for obtaining objective assessments of stride length during physical activity by an accelerometer under controlled condition. The purpose of the present investigation was to examine the relationship between the stride length under free-living condition and the whole body muscle mass in older adults. [METHODS] Forty adults, aged from 63 to 85, participated in the present investigation (71+/-5 years of age, 160+/-7 cm of height, 57+/-8 kg of body weight, 19 women and 21 men). All participants wore a pedometer with an accelerometer (Lifecorder-4sec, Kenz, Japan) for 7 days continuously under free-living condition. In 1-min interval, the walking distance and the number of steps was obtained; thereafter the minute-by-minute stride length was also calculated. In the present investigation, the stride length during moderate intensity physical activity (MVPA) was evaluated. The body composition including the lean body mass (LBM) and the muscle mass (MM) was estimated by the bio-impedance analyses. [RESULTS] In women, the time spent in MVPA at <70 cm of the stride length was negatively associated with the LBM and MM ($p<0.05$). Furthermore, the time spent in MVPA at >90 cm of the stride length was positively associated with the LBM and MM ($p<0.05$). In contrast, no significant relationship was obtained between the patterns of the stride length and the body composition in male participants. [DISCUSSION] The results of the present investigation demonstrated that the significant associations between the patterns of the stride length during free-living condition and the body composition in older women. Interestingly, the time spent in the MVPA at narrow stride length and wide stride length differently associated with LBM and MM. The wider stride length may be recommended to reduce the risk of the sarcopenia in older women. The relationship between the stride length under free-living condition with whole body muscle mass remain unclear in older men.

DOES THE SENSORY PROFILE CORRELATE WITH DAILY ACTIVITY IN ADULTS AND OLD ADULTS

KODESH, E., ENGEL-YEGER, B.

University of Haifa

Introduction The organization of sensory inputs is necessary to adapt to situations in daily life. Dunn's model of sensory processing explains behavioral responses to sensations and the relationship between neurological thresholds and behavioral responses. Regular physical activity such as walking is a common health promotion strategy, yet participation is insufficient. Many factors contribute to participation in physical activity. The relationship between sensory processing and physical activity capacity in adults has not been examined. **Methods** Ninety one participants (men 37) aged 45-80 years divided according to their ages: adult 45-59 years (n=48), and old age 60-80 years (n=43) participated. None of the participants lived alone and all were free of chronic diseases. Each participant filled in a sensory profile questionnaire (The Adolescent/Adult Sensory Profile (AASP)) and results were categorized as: Low Registration, Sensation Seeking, Sensory Sensitivity, and Sensation Avoiding. Participants wore a StepWatch 3 Activity Monitor (SAM; Cyma Corporation, Mountlake Terrace, WA) to collect data on ambulatory activity for 4 days. MANOVA with Bonferroni post hoc test examined the differences in activity level between age groups. Linear regression was performed to examine whether sensory processing abilities and age can predict physical activity. **Results** The adult group had a higher step count than the old age group ($p<0.01$), with less inactivity phases and more time spent doing activities with low and medium intensity. Participants who registered sensory input less efficiently, were more inactive than those who registered sensory input in an adequate manner (based on the AASP norms) ($p<0.01$). Inactivity time during the day was predicted by age (8%) ($p=.006$), meaning that the old age group had greater inactivity. Low registration sensory profile added 4% to the prediction ($p=.05$) indicating that people registering less sensory input had a greater tendency for inactivity. On the other hand, high activity levels were predicted by lower sensitivity (6%) ($p=.016$). **Discussion** The present study provided evidence that in addition to age, the sensory profile plays a role in the intensity and amount of daily physical activity determined by step count and frequency. The sensory profile was found to be predictive of activity level and the relationship between sensory processing and behavioral management was revealed. This fact needs to be considered when physical activity programs are prescribed.

MULTI-COMPONENT EXERCISE TRAINING IN ELDERLY DAY CARE CENTERS: A PILOT STUDY

RODRIGUEZ, A., ARRIETA, H., YANGUAS, J.J., MARKOTEGI, M., IRAZUSTA, A., GIL, S.M.

UNIVERSITY OF THE BASQUE COUNTRY

Introduction Evidence has shown that supervised exercise interventions offer benefit regarding both physical and cognitive health, particularly for frail community dwelling older people (Andy et al., 2015). On the other hand, multi-component exercise intervention composed by strength, endurance and balance training seems to be the best strategy to improve rate of falls in physically frail older adults (Cadore et al. 2013). However, the optimal program for each specific elder population remains unclear. In the present study, we analyzed the effect of a multi-component exercise program on elder people who attend a Day Care Center. **Methods** Participants were community dwelling elderly from Matia Day Care Center, which were randomized in two groups: Control and Experimental (a multi-component exercise session per week during 3 months). Inclusion criteria included: aged ≥ 70 years, scored ≥ 50 on the Barthel Index, scored ≥ 20 on MEC Test (an adapted version of MMSE in Spanish) who were all capable to walk independently for 10 m. Physical activity by accelerometry, and anthropometric and physical parameters were analysed before and after the programme. **Results** The average age \pm SD of participants was 83.14 ± 5.50 . At baseline, 80% of participants did less than 30 minutes of moderate physical activity per week (median (IR) 1 min/day (4.76)). After the intervention, the experimental group improved significantly in 8 Foot Up and Go Test ($p<0.05$), and increased in arm flexion and sit to stand tests (%16.3 and %12.3 more repetitions), 6 minutes walking test (%5.8 more distance) and fast walking speed at 2,44 and 4 meters (%4.6 and %3.0 less time), while control group showed a decline in those test performance. **Discussion** There is some indication that long-lasting multi-component exercise program performed in Elderly Day Care Centers could be beneficial in order to slow or even improve physical fitness of participants. Results also showed that studied Day Care Center people do not fulfill the recommendations of WHO to do at least 150 minutes of moderate physical activity per week. Future investigations are needed to identify optimal programs. Particular attention need to be paid by managers and staff in Elderly Day Care Centers. References Andy C. Y., Wong T. W., Lee P. H. (2015). Sports medicine-open, 1(1), 1-13. Cadore E. L., Rodríguez-Mañas L., Sinclair A., Izquierdo M. (2013). Rejuvenation research, 16, 105-114.

A PILOT TRIAL OF MULTI-COMPONENT EXERCISE TRAINING IN OLDER RESIDENTS IN LONG-TERM RESIDENTIAL CARE FACILITIES

ARRIETA, H., RODRIGUEZ, A., ITURBURU, M., KORTAJARENA, M., IRAZUSTA, J.

University of the Basque Country (UPV/EHU)

Introduction The literature has shown that participation in regular physical activity protects against diverse components of frailty syndrome by increasing balance and mobility and reducing falls, as well as institutionalization, hospitalization and mortality (de Labra et al., 2015). A multi-component exercise intervention programme seems to be the best strategy for improving gait, balance, strength, as well as reducing rate of falls in older individuals (Cadore et al., 2013). However, more studies are needed to determine which exercises are best suited, most effective, and safest for institutionalized population (Aguirre and Villareal, 2015). Thus, our aim was to describe the possible effect of a multi-component exercise programme in older residents in Long-Term Residential Care Facilities. **Methods** A multi-component exercise programme including strength, balance and aerobic exercises was carried out (3 sessions/week during 3 months) with institutionalized elderly from Matia Residential Care Facilities. Inclusion criteria were: age ≥ 70 , score ≥ 50 on the Barthel Scale, ability to walk independently for 10m and score ≥ 20 in the MEC Test (the adapted version of MMSE to Spanish). Anthropometric (bioelectric impedance) and physical parameters (accelerometry, normal and fast Gait Speed and Senior Fitness Test) were analysed. **Results** 92% of the participants (aged 86.55 ± 7.83) did less than 15 minutes of moderate physical activity per week (median (IR) 1.08 (0.75)). Improvements on different physical parameters such as Arm Flexion ($P<0.05$) and Chair Stand (22.2% and 20.0% more rep.), 8 Foot Up and Go, normal and fast Gait Speed (7.4%, 11.8% and 7.1% less time) and 6 Minutes Walking Test (2.4% more meters) were observed. Fat percentage and the level of physical activity measured with accelerometry did not change from the week before to the week after the programme. **Discussion** Participants in Long-Term Residential Care Facilities are not active enough comparing the results with the recommendation of WHO to do at least 150 minutes of moderate physical activity per week. The results of the pilot study seem to demonstrate that a multi-component exercise program is effective to improve aerobic capacity, strength and dynamic balance of institutionalized individuals. Further studies are needed to assess the specific exercise programmes and strategies to increase physical activity in institutionalized older people. References

COMPARISON OF AEROBIC VERSUS RESISTANCE VERSUS COMBINED EXERCISE IN OLDER ADULTS AT RISK FOR AGE-RELATED FUNCTIONAL DECLINE

TIMMONS, J.1, MINNOCK, D.1, HONE, M.1, MURPHY, J.C.3, EGAN, B.1,2

University College Dublin

1Institute for Sport & Health, 2Institute of Food & Health, School of Public Health, Physiotherapy and Sports Science, University College Dublin; 3Medfit Proactive Healthcare, Blackrock, Co. Dublin. Introduction Regular exercise can help delay the onset of development of lifestyle-related chronic diseases such as type 2 diabetes, obesity, and sarcopenia as well as maintaining physical and cognitive function. However, mode-specific exercise effects are not well-studied in older adults. The present study is investigating exercise training in older adults (>65 y) through a comparison of aerobic (AER) versus resistance (RES) versus combined (CEX) exercise training. Methods Participants (n=42; m/f 22/20), were divided into four groups: control (CON), AER, RES, and CEX. Each training group trained three times per week for 12 weeks. CEX comprised of 12 min of resistance training (6 exercises x 1 min each x 2 sets) and 12 min of aerobic training per session (3 x 4 min at 80% of predicted HRmax). AER comprised of 24 min of aerobic training (6 x 4 min at 80% of predicted HRmax). RES comprised of 24 min of resistance training (6 exercises x 1 min each x 4 sets). CON were advised to continue with their current physical activity levels and both the training groups and control group were asked to maintain their current dietary habits. Pre- and post-intervention assessments included body composition (DXA), handgrip strength, Short Physical Performance Battery (SPPB), Montreal Cognitive Assessment Test, Chester step test, stair climbing test, and upper and lower limb strength tests (1 RM chest press and leg press). Results The results thus far represent preliminary findings as the study is on-going and n-sizes will be approximately doubled. Significant improvements have been observed in 1 RM leg press in all three training groups whereas at current n-sizes we observe differential effects of training on improvements in grip strength (RES, CEX only), sit-to-stand (AER, CEX only), timed up and go test (AER, CEX only), 1 RM chest press (RES, CEX only), and reduction in body fats (RES, AER only). CEX only was effective in improving gait speed, leg power. Neither whole body or leg lean body mass (LBM) has changed in any training group, but arm LBM has tended to increase in CEX only. Discussion For many of the other parameters, preliminary results suggest there is positive evidence for CEX, and differential responses for AER and RES, with suggested support for CEX and AER over RES in relation to many of parameters tested. On study completion with larger sample size and complimentary analysis of plasma markers of metabolic health, we anticipate extraction of mode-response relationships for key training variables, thus informing practitioners to design effective training programmes for older adults. EFFECT OF YOGA EXERCISE ON AGE-RELATED DECLINE IN AUTONOMIC NERVOUS SYSTEM ACTIVITY IN WOMEN

KIMOTO, R.1, KAMBAYASHI, I.2, TSUKAMOTO, M.3, AKITSUKI, A.2, FUKUSHI, M.4, SHIONOYA, A.5

1: National Institute of Technology, Asahikawa College, 2: Hokkaido University of Education Sapporo, 3: Tokai University, 4: Yoga Life School in Sapporo, 5: Nagaoka University of Technology

Introduction The autonomic nervous system (ANS) maintains homeostasis through the balance of the sympathetic and parasympathetic nervous system. Currently, the analysis of heart rate variability (HRV) offers an indirect, non-invasive assessment of ANS activity. Age-related, early-onset, progressive decline in ANS parameters of HRV has been reported. Moreover, autonomic nervous activity disorder plays an important role in climacteric symptoms in menopausal women. Therefore, the purpose of this study was to investigate the effect of yoga exercise on the age-related decline in autonomic nervous system activity in women. Methods A total of 113 healthy women (age 45.4 +/- 12.4 years) who took a yoga course regularly participated in this study. They attended a 90-120 minute yoga exercise session conducted by a well-qualified instructor. ANS activity was assessed before and after the yoga exercise session by HRV power spectral analysis, which enabled us to identify separate frequency components: total power (TP), low-frequency (LF; sympathetic nervous system activity) power and high-frequency (HF; parasympathetic nervous system activity) power. Statistical analysis was performed using the following tests: Pearson's correlation coefficient and Student's t-test. Results With regard to the relationship between ANS activity at rest and age in subjects who did yoga regularly, We found a negative correlation between the ANS parameters and aging in subjects with less than 5 years of yoga experience (n=66) [LnTP ($R^2=0.14$), LnLF ($R^2=0.11$) and LnHF ($R^2=0.27$)]. Whereas, no significant correlation was found in subjects with more than 5 years of yoga experience (n=47). The changes in ANS parameters before and after one yoga lesson were investigated in subjects aged 40 and older who have been decline ANS activity (n=77). LnTP ($p<0.01$) and LnLF ($p<0.01$) were significantly increased after the yoga session. LnHF tended to be increase after the yoga session ($p<0.1$) in subjects aged 60 and older. Discussion In subjects with more than 5 years of yoga experience, there was no significant correlation between the ANS parameters at rest and aging. Furthermore, ANS activity significantly increased after yoga exercise. Therefore, we concluded that yoga exercise in daily life enhances ANS activity and improves the autonomic balance. Because autonomic nervous activity disorder plays an important role in climacteric symptoms in menopausal women, yoga exercise may be effective in relieving these symptoms. AGE AND THE EFFECT OF EXERCISE, NUTRITION AND COGNITIVE TRAINING ON OXIDATIVE STRESS

FRANZKE, B., SCHÖBER-HALPER, B., HOFMANN, M., OESEN, S., TOSEVSKA, A., STRASSER, E.M., WESSNER, B., WAGNER, K.H.
University of Vienna

Introduction: The purpose of this study was to investigate the effect of six months resistance training – using elastic bands – alone or combined with a nutritional supplement, and cognitive training on markers of oxidative stress and antioxidant defense in Austrian institutionalized elderly. In respect to the very old age of our study population we further compared subjects above and below their statistical life-expectancy (LE) regarding their responses to the intervention. Methods: Participants (n=105) were randomly assigned into the three intervention groups –elastic band resistance training (RT), RT combined with protein and vitamin supplementation (RTS) or cognitive training (CT) – and performed two guided training sessions per week for a duration of six months. Markers for oxidative stress (MDA, 8oxodG,

8oxoGuo), antioxidant defense (uric acid, FRAP, SOD, CAT, GSH-Px) and DNA strand breaks (comet assay) were analyzed and also transformed into an "antioxidant factor" to compare the total effect of the intervention. Physical fitness was assessed by the six-minutes-walking, the chair-rise and the handgrip strength tests. Results: At baseline we observed significant negative correlations between 8oxoGuo and handgrip strength ($r = -0.350, p = 0.001$) as well as between high sensitive troponin-T and the 6-minutes-walking test ($r = -0.210, p = 0.035$). Both, RT and RTS groups, showed significant improvements in walking and chair-rise performance after six months. However, only subjects of the RT group ($\Delta 4.9 \pm 7.2$ points) demonstrated an about twice as high non-significant increase in "antioxidant factor" compared to RTS ($\Delta 2.4 \pm 7.6$ points) and CT ($\Delta 2.2 \pm 6.5$ points) groups over the 6 months. Interestingly, this difference became significant (RT vs. RTS/CT, $p < 0.05$) analyzing subjects over their statistical LE, whereas no difference was observed between the intervention groups under LE. Conclusion: Especially in very old subjects, a better fitness level seems to reduce oxidative DNA damage and decrease levels of cardiac risk markers. Interestingly, subjects over their statistical LE were more susceptible to six months of elastic band resistance training regarding the general oxidative state, compared to elderly under their statistical LE. However, the antioxidants of the provided supplement might have contributed to a suppression of the optimal adaptation to exercise of the redox-system in the RTS group.

EXERCISE REDUCES CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH ALZHEIMER'S DISEASE.

SCHENA, F.

University of Verona

Introduction: Alzheimer disease (AD) is the leading cause of dementia beginning with impaired memory. Several factors has been associated with increased risk of AD, but among those, cardiovascular disease are the most consistently reported. Hypertension, diabetes, obesity and dyslipidemia have all been found to increase the risk of dementia. Although AD patients present a high cardiovascular risk (CVR), AD conventional therapy consists in cognitive treatments. Even though literature underline some exercise-induced positive effects in patients with AD, the effects of exercise training (ET) on CVR in AD are still mated of debate. Therefore, the aims of this study were to determine alterations of CVR markers in AD patients and to compare the effects of ET with respect to conventional cognitive treatment (CCT) in patients with AD. Methods: In seventeen patients with AD (77 ± 7 yrs) and 11 age-matched healthy controls (OLD), CVR markers (glycaemia, HDL, LDL, triglycerides, systolic and diastolic blood pressure, and BMI) were measured. Following, AD patients were randomly assigned to ET group ($n=8$) or CCT group ($n=9$) that performed 72 treatment sessions, 3 times a week. ET included 90 min of aerobic and strength training. CCT included cognitive multi-modal stimuli (visual, verbal, auditory). Baseline measurements (T0) were repeated after 6-month of treatment (T1). Results: In comparison to the OLD group AD patients exhibited significant aggravation of some CVR markers (systolic and diastolic blood pressure +15.6% and +13.8% respectively, glycaemia +10.5%, triglycerides +18.0%). HDL, LDL and BMI did not differ significantly. After ET some of the CVR markers were significantly ameliorated (systolic and diastolic blood pressure -5.2% and -6.4% respectively, glycaemia -12.6%, triglycerides -23.9%). HDL, LDL and BMI did not change significantly between pre- and post ET. The CCT group did not show any change in the CVR markers between pre- and post treatment. Conclusion: Data from the current study confirm that AD patients present higher CVR factors compared to age-matched counterparts. Furthermore, only ET program improved most of the CVR markers. The results are particularly remarkable considering that hypertension, disorder of glucose or insulin and other CVR markers could play pivotal role not only in onset of AD but even in its progression. Indeed, diabetes, hypertension, obesity, dyslipidemia and metabolic syndrome are positively associated with blood brain barrier dysfunction, hyperinsulinemia, adipokines and cytokines production, and increased oxidative stress. These conditions, possibly leading to an increased brain amyloid β deposition worsening the AD progression, could be faced by a 6-month ET program.

MO-PM23 Fitness Perception & Performance

FITNESS SELF-PERCEPTION IN RUGBY PLAYERS IN COLOMBIA: PART I

MARTÍNEZ-RUEDA, R.1, ANGARITA, A.2, ALBA, P.L.3, SAAVEDRA, I.3

1. Universidad Santo Tomás /Bogotá, Colombia 2. Universidad de Santander /Bucaramanga, Colombia 3. Universidad Manuela Beltrán /Bogotá, Colombia

Introduction: Rugby research has been focused on the assessment of the anthropometric and physiological players' profiles, as well as injuries related to its practice leaving aside other issues such as self-perception, which has a significant influence on subjects' self-esteem and performance. The aim of this study was to evaluate the Fitness self-perception in Rugby players in Colombia. Methods: A cross-sectional study was conducted in Rugby players from 7 cities in Colombia, aged 18 and older and with at least a year of sport practice ($n=116$; 70.7% male, 29.3% female; 57.8% Backs and 42.2% Forwards). Fitness self-perception was assessed using the International Fitness Scale (IFIS) questionnaire (Español and Ramírez, 2014). Results: The medians of age and sport practice were 23 and 3 years, respectively. Most players (63.4%) reported their General Physical Fitness and its components as 'Good'. There were no significant differences by position on the field or sex in General Physical Fitness self-perception. Cardiorespiratory Fitness was better self-perceived by men who referred it as 'Good' while women as 'Average', without significant differences by position on the field. Muscular Strength was also rated as 'Good' by players, particularly women, with no significant differences between groups. In Speed/Agility players perceived themselves as 'Good'; most Backs (65.7%) value it as 'Good' while most Forwards (46.9%) as 'Average' showing the same pattern for Flexibility, perceiving it as 'Good' without significant differences by gender. According to their position on the field, Forwards have a lower perception of their Flexibility, which considered 'Average' while Backs referred to it as 'Good'. Discussion: Our results are consistent with previous players profile descriptions. The differences found between players are related to the specificity of the position on the field, especially in Speed/Agility; Backs stand out as being faster than Forwards (Da Cruz-Ferreira and Fontes, 2011). In a highly demanding physical sport like Rugby, is important to test self-perception due to individual self-perception influences performance (Weston et al., 2011). Our study has as limitation that we did not compare fitness profile and fitness self-perception; but it could address an important issue to improve in these athletes. RELATIONSHIP BETWEEN PERCEIVED PHYSICAL LITERACY AND PHYSICAL ACTIVITY LEVELS AMONG HONG KONG ADOLESCENTS

SUM, K., LEUNG, F., NG, R., CHOI, S.

The Chinese University of Hong Kong

This study aims to investigate the relationship between perceived physical literacy (PL) and physical activity (PA) levels among Hong Kong adolescents. Over 5400 students from 15 secondary schools (ages 12-18) in Hong Kong were recruited into this cross-sectional study. Self-report scores from perceived PL and PA levels were recorded by using Perceived Physical Literacy Instrument (PPLI) and International Physical Activity Questionnaire for Adolescent (IPAQ-A). A random sub-sample (N=450) from 15 participating schools wore accelerometers (Actigraph GT3X+) to measure PA for at least 8 hours per day in 7 consecutive days as objective measures for students' PA level. The research team first validated the relationship between IPAQ-A and accelerometer, and then confirmed the relationship between the perceived PL and PA levels. Pearson's Product-Moment Correlation used to calculate the relationship between the self-reported MET minutes per day from IPAQ-A and PA minutes per day in each intensity level from the accelerometer. Correlations between PL and PA of participants were examined. The overall correlation was compared with age, gender, academic achievement and socio-economic status. The findings were useful in intervening in the perception of PL and participation in PA for adolescents in Hong Kong. The results can help promoting an active and healthy lifestyles to adolescents, and finally, preventing chronic diseases in the future.

DEVELOPMENT IN PERFORMANCE ON THE ANDERSEN SHUTTLE RUN TEST IN BOYS AND GIRLS 6 TO 11 YR OLD

MAMEN, A., WESTERBERG, A.C., HJELLE, O.P., FREDRIKSEN, P.M.

Kristiania University College, Oslo

Introduction The Andersen intermittent shuttle run test is a popular fitness test for children and adolescents (Andersen et al. 2008). As for other shuttle run tests, test performance increases with age, but that is not well documented for this test. Thus, we have compared the test performance development of children 6 to 11 yr doing the Andersen test. Methods 2010 children aged 6 to 11 took part in the study which went on for six months at seven different schools. The test was explained and the children were especially instructed to stand still in the rest periods, and to run at an even pace in the work periods, doing as best as one could. Test personnel counted the number of shuttles each child ran. The running site had cones for every 5th m used for calculating the total distance covered. The test was run once. The linear regression between age and distance was calculated and differences in slope between age 6 to 8 and 9 to 11 was analysed with independent t-test assuming homoscedastic variance. Results presented are the slope (standard error of regression) unless otherwise noted. A significance level of $p < 0.05$ was used. Results The mean distance covered increased by age, from 777 m to 1020 m at age 6 and 11 yr for the boys and girls combined. The slope was 78.7 (4.8) m·yr⁻¹ from age 6 to 8. From age 9, it was 39.0 (4.4) m·yr⁻¹, $p < 0.001$. For the oldest group, the slope also differed between boys and girls, 35.3 (6.6) m·yr⁻¹ vs 49.8 (6.9) m·yr⁻¹, $p < 0.001$. Both height and body mass increased linearly from 6 to 11 yr. Between 6 and 8 yr the height increased with 0.059 (0.002) m·year⁻¹ and body mass 3.3 (0.2) kg·year⁻¹. The oldest group had a height increment of 0.060 m (0.002) m·year⁻¹ and 4.2 (0.3) kg·year⁻¹ for body mass. These differences were not statistical significant. Discussion We found a statistical significant difference in the slope of distance covered in the Andersen test between those aged 6 to 8 and 9 to 11 yr. This difference is not related to bodily changes, as both height and body mass rates were not statistical different between the two groups. Motivation and learning are two factors that are important for physical performance. If the 6 yr old found the test difficult to perform, a learning effect can explain the steeper increase the first three years, and from age 9, a ceiling effect appears. The difference in slope between sexes in the oldest group may be related to onset of puberty for the girls. If so, a new increase in slope would be expected for the boys from age ~13 yr. STUDY OF PHYSICAL ACTIVITY AND FITNESS IN PRIMARY CARE PROFESSIONALS

BOFILL-RÓDENAS, A.1, RODRÍGUEZ-ÁLVAREZ, M.M.1,2,3, SUBÍAS, P.2,3, NOGUERA-FRANCO, M.2

1: Universitat de Girona; 2:Catalan Institute of Health, Primary Care; 3: Multidisciplinary Teaching Unit Girona

INTRODUCTION Physical inactivity is recognized as one of the biggest risk factors in the development of heart disease. From the Primary Care are promoted health prevention activities but it is unknown whether the staff practice them. The aim of this study is to know weekly hours with moderate-intense physical activity and the degree of sedentary lifestyle of the professionals in a Primary Care Center, as well as to describe physical state and analyze its association with the degree of physical activity, sedentary lifestyle and self-rated health. METHODS Cross-sectional study by administering at the initial visit different questionnaires [7-day physical activity, RAPA, VREM and self-rated health questionnaire (EQ-5D)] to the professionals of a primary care centre in Barcelona province. Each participant was provided with a pedometer. Heart rate variability was measured with the Polar Heart Rate Monitor RS800 performing 10-minute measurements in the early morning in both supine and sitting position. Time and frequency spectrum were analyzed using Kubios software. RESULTS 46 primary care professionals were recruited. 71,7% Females. Age 44,5 (SD 10,2). BMI 25,7 (SD 5,7). 21,8% administrative, 30,4% nursing and 47,8% medical. 21,74% were active, 13,04% moderately active, 65,32% inactive or indolent. 19,47% did usually strength exercises and 34,78% elasticity exercises. 86,94 % reported good/very good self-rated health and 6,51% poor/very poor. 32,61 % never walk and 15,22 % walk every day. 19,57 % walk 30 minutes/day. 43,48% do not do any kind of sport and 10,87%. 52,17% index LF/HF<1,5. LF/HF 2,37 (SD 2,64) 9.9 days/month were dedicated to walk (41 minutes/session). Participants performed 7,740 steps/day on average. 7.4 days/month engaged on sports (38 minutes/day). DISCUSSION Participants generally have good self-rated health but a lack of physical activity is evidenced. Participants showed a predominance of the parasympathetic system in the HRV analysis. Most important limitations are the cross-sectional nature of the study and the size of the sample. REFERENCES Ruiz Comellas A, Pera G, Baena Díez JM, Mundet Tudurí X, Alzamora Sas T, Elosua R, et al. DO JUNIOR FEMALE ATHLETES ADAPT BETTER THAN MALE COUNTERPARTS AFTER TRAVELING TO A FOREIGN COUNTRY?

TSUKAHARA, Y., YAMASAWA, F., AZUMA, K., MATSUMOTO, H., KASUGAI, Y.

Keio University School of Medicine

BACKGROUND Although many elite athletes go abroad for international competitions and training nowadays, junior athletes may find it difficult to adapt to new environment because of their paucity of experience. Little has been studied, however, about the consequences of travelling to a foreign country on junior athletes and their response to it. **PURPOSE** To evaluate their ability to cope with new environment and search for any differences of the ability between the genders. **METHODS** Forty-one top-level Japanese junior track and field athletes (22 boys and 19 girls, aged 16.0±0.7 years) who traveled from Tokyo to Colombia via New York in order to participate in an international competition were involved in this study. They filled a questionnaire regarding, performance, sleep problems, appetite, fatigue and jet-lag, 8 times from day 1 through day 8, before they went to bed. The answers were scored by visual analogue scale from -5 (very negative compared to usual status, which is scored as 0) to 5 (very positive compared to usual status). All data were analyzed using Wilcoxon's rank test. **RESULTS** While there was not a significant difference relating to sleep problems, the boys felt less flexible (-1.1±1.5 and 0.2±1.3 respectively, p<0.05) and more fatigued (-1.6±1.5 and -0.6±1 respectively, p<0.05) than the girls on the first day. In addition, the boys were not able to taste food as good as the girls, during the whole 8 days (-0.1±1.9 and 1.3±2 respectively, p<0.05) and this was more prominent during the first 4 days than the latter. **DISCUSSION** Since amount of sleep in the aircraft and other factors during the flight did not show any gender differences in our study, we speculated that adaptability to the change of environment differs between boys and girls. Since Anshel et al reported that the way of coping with acute stress relating to performances differs between the genders, further investigation is required to seek for difference in managing themselves with new environment. Although difference in taste preferences between the genders was recognized, it might only reflect the fact there is a possibility that the girls merely preferred the local food than the boys and not be derived from difference in adaptability. Thus, we need information after traveling to other countries as well and further research is required. **REFERENCE** Anshel et al. Racial and gender differences on sources of acute stress and coping style among competitive athletes. *J of social psychology*. (2009),149(2),159-177. **CONTACT** yuka.voila@gmail.com

CIRCUMSTANCES OF FALL DIFFER BETWEEN FEMALE AND MALE MOUNTAIN HIKERS

FAULHABER, M., WÜRTELE, A., BURTSCHER, M.

University Innsbruck

Introduction Mountain hiking is the most attractive mountain-sport activity in the Alps during the summer season with some million hikers in Austria each year (Burtscher et al., 2007). Mountain hiking is defined as walking in a mountainous environment predominantly on marked trails and paths. Mountain hiking is generally characterized as a long-lasting activity including a large muscle mass with a predominantly moderate intensity which is considered beneficial for health (Powell et al., 2011). The other side of the undoubtedly positive health effects of mountain-hiking activities is the risk of accidents, emergencies and even fatalities. Preliminary analyses of mountain-hiking accidents revealed that a) about 50 % are caused by falls and b) differences between female and male hikers can be considered (Faulhaber et al., 2012). Therefore the goal of the present project was to provide information on the circumstances of mountain-hiking accidents caused by falls based on data of a more-year period focusing on differences between female and male victims. **Methods** Non-fatal and fatal accidents during mountain hiking in Austria, which were documented by the Austrian Alpine Police (Ministry of the Interior) during a 9-year period (summer seasons 2006 to 2014) were included into the retrospective analysis. Documentation was performed using standardized forms and data input was conducted by instructed staff of the Austrian Alpine Police. Anonymized data was provided to the University of Innsbruck for analyses. Characteristics of female and male victims were compared by unpaired t-tests or Chi-square tests as appropriate. **Results** Data of 6022 victims with known sex were included into analyses (48 % female, 52 % male). Female victims were slightly older compared to male victims (53±17 vs. 51±19 years, p<0.01). Fatal accidents were more frequent among males (8.9 %) compared to females (3.2 %). In both sexes accidents happened predominantly during the ascent (81 % in females, 76 % in males, p<0.01 between sexes). Only 0.6 % of the female hikers seem to have consumed alcohol on the day of the accident compared to 3.5 % of the male hikers (p<0.01). **Discussion** Although the results have to be interpreted carefully since only more severe accidents with the need of external help (e.g. rescue) were included, the results indicate that there are clear sex specific differences. Further studies should focus on risk factors for falls in mountain hikers focusing on sex-specific aspects. **References** Burtscher M, Pachinger O, Schocke MFH, Ulmer H. COMPARING THE SUBACROMIAL SPACE AT 90° SHOULDER ABDUCTION WITH AND WITHOUT EXTERNAL HUMERUS ROTATION AND DURING UPRIGHT ROW POSTURES IN YOUNG HEALTHY SUBJECTS: AN ULTRASOUND EVALUATION

LONGO, S.1, CORRADI, A.1,2, MICHIELON, G.1, SCURATI, R.1, SARDANELLI, F.1,3, SCONFRENZA, L.M.3

1Università degli Studi di Milano, 2,3IRCCS Policlinico San Donato, Italy.

Introduction The lateral rises performed with or without humerus rotation (shoulder abduction up to 90° and above), and the upright row (UR) performed with dumbbells or barbells implying an internal humerus rotation (shoulder abduction >90°) (Durall et al., 2001) are common exercises employed by people in gyms. However, the UR can be related to the onset of subacromial impingement syndrome (SIS) (Kolber et al., 2014). Conversely, it seems that the lateral rises with an external humerus rotation are not associated with SIS onset. Since one of the factors involved in the onset of SIS is the reduction of subacromial space (SS), we evaluated SS at different shoulder postures that reproduced the final positions of the abovementioned exercises. **Methods** Twenty-five healthy males (age, 24±5 yrs; stature 175±8 cm; body mass 74±12 kg) underwent SS ultrasound evaluation of the right arm with sagittal anterior approach. A line was marked on the skin at the mean point of the anterior acromial aspect found by ultrasound. Scans were taken while executing with (WL) and without (NL) 4-kg load: 90° shoulder abduction (SA) with no humerus rotation (90°nl); 90° SA maximum external rotation (90°er); SA during upright row (UR). A fluid goniometer was attached with a Velcro® strap on the back of the arm to check the SA degrees. Reliability was assessed. Repeated measures ANOVA 3x2 and paired samples t-test were employed ($\alpha=0.05$). Results Significant differences between loads ($p=0.003$, $\eta^2=0.37$), angles ($p<0.001$, $\eta^2=0.72$), and significant interaction ($p=0.004$, $\eta^2=0.45$) were found. SS values were higher at 90°er compared to 90°nl and UR ($p<0.001$ for both) in WL. Differences were found between 90°nl and both 90°er ($p=0.002$) and UR ($p=0.009$) in NL. Differences between NL and WL were found at 90°er ($p<0.001$). Intra-observer reproducibility was optimal for all measurements (range 0.97–0.99). **Conclusion** In our participants, postures of SA at 90°er showed larger SS than at 90°nl and UR both WL and NL. This

could imply that excluding the external humerus rotation during SA may be potentially dangerous in susceptible subjects, favouring the onset of SIS. References Durall CJ, Manske RC, Davies GJ. TESTING A MODEL OF SUCCESSFUL AGEING IN A COHORT OF MASTERS SWIMMERS

GEARD, D.1, REABURN, P.1, REBAR, A.1, DIONIGI, R.2

1: Central Queensland University (Rockhampton, Australia), 2: Charles Sturt University (Bathurst, Australia)

INTRODUCTION Successful ageing (SA) can be defined as high physical, psychological, cognitive, and social functioning in later life (Bowling, 2007). Masters athletes train for, and compete in, sport specifically designed for older adults (Reaburn & Dascombe, 2008). Due to their high levels of physical function, masters athletes are often proposed as exemplars of SA (Cooper et al., 2007; Hawkins et al., 2003). However, the SA status of masters athletes is yet to be tested using a SA model which incorporates measures of psychological, cognitive, and social functioning. The aim of this study was to propose a model of SA and determine if data from a cohort of masters swimmers fit the proposed model. **METHODS** A SA survey comprising standardised measures was administered to a sample of 169 masters swimmers (males N = 66; females N = 103) competing at the 2013 Australian Masters Swimming Championships. Structural Equation Modelling was used to determine if our conceptual SA model mapped onto data collected from the masters swimmers. One hypothesised model and four alternative conceivable SA models were tested to determine which model best fit the data. The variables we included were self-rated SA and physical, psychological, cognitive, social functioning. **RESULTS** The best fitting model was the hypothesised one with the latent factors of physical ($b = 0.31$, $SE = 0.11$), psychological ($b = 0.25$, $SE = 0.11$), cognitive ($b = 1.08$, $SE = 0.79$), and social ($b = 1.20$, $SE = 0.63$) functioning all loading onto the higher order SA factor. The self-rated SA manifest variables also significantly loaded onto the SA latent factor ($\text{all } ps < .05$). **DISCUSSION** Our study found that high self-rated SA represents underlying physical, psychological, cognitive, and social functioning. Our findings provide evidence that SA is a multifaceted construct which incorporates more than just physical health. Future directions for research include testing this model in a cohort of non-masters athletes to determine if the same SA model holds. **REFERENCES** Bowling, A. (2007). MO-BN01 Running Biomechanics

RELATIONSHIPS IN 800 METER RUNNING PERFORMANCE AND AEROBIC AND ANAEROBIC RUNNING CAPACITIES IN HOMOGENEOUS MIDDLE-DISTANCE RUNNERS

TANJI, F., SHIMAZU, W., TSUJI, T., ENOMOTO, Y., NABEKURA, Y.

University of Tsukuba

Introduction Most long-distance running performances can be explained by three physiological variables: maximal oxygen uptake ($V_{\text{L}} \cdot O_2\text{max}$), running economy (RE), and lactate threshold (LT); however, a model explaining 800 m running performance has not been established. Aerobic and anaerobic metabolisms contribute 60% and 40%, respectively, to the overall energy expended during an 800 m running event (Hill, 1999), having greater metabolic capacities for both is essential for the best performance. Maximal accumulated oxygen deficit (MAOD) and peak accumulated blood lactate concentration (ΔbLa), known as the anaerobic metabolic capacity, are related to 800 m running performance (Bosquet et al., 2007). The purpose of this study was to clarify the relationships with 800-m running performance and aerobic and anaerobic running capacity in homogeneous performance runners, and to investigate a model to explain 800 m running performance. **Methods** Ten male university student middle-distance runners (age 19.6 ± 1.0 yr; height 170.5 ± 4.8 cm; body mass 58.8 ± 3.3 kg; 800 m personal best time $1'52''4 \pm 1''9$) took part in this study. They carried out four running tests within 7 days: 800 m, maximal, submaximal (65, 70, 75, 80, 85 and 90 % $V_{\text{L}} \cdot O_2\text{max}$) and supramaximal tests ($121.7 \pm 4.4 \%V_{\text{L}} \cdot O_2\text{max}$). RE was estimated as energy cost (kcal/kg/km) during 65% $V_{\text{L}} \cdot O_2\text{max}$ running, LT was expressed as intensity of $V_{\text{L}} \cdot O_2\text{max}$. Results A significant positive relationship was observed between 800 m running performance (25.0 ± 0.8 km h $^{-1}$) and $V_{\text{L}} \cdot O_2\text{max}$ ($p < 0.05$) but not MAOD ($p = 0.76$), RE ($p = 0.60$), LT ($p = 0.09$) and ΔbLa ($p = 0.12$). 57.2% of the 800 m running performance was explained by $V_{\text{L}} \cdot O_2\text{max}$ ($VIF = 1.33$), LT ($VIF = 1.15$), RE ($VIF = 1.22$), MAOD ($VIF = 2.05$) and ΔbLa ($VIF = 1.64$) ($p = 0.13$). **Discussion** This study showed that $V_{\text{L}} \cdot O_2\text{max}$ was the most important variable in an 800 m running performance. On the other hand, ΔbLa explains the variables for 800 m running performance better than MAOD. It was suggested that MAOD was not an important variable to estimate the 800 m running performance in homogeneous performance runners. Aerobic metabolism contributes to 60% of the overall energy expended during an 800 m run (Hill, 1999), however 800 m running performance was explained 57.2% by even aerobic and anaerobic physiological variables in homogeneous performance runners. **References** Hill DW. ALTERED NEUROMUSCULAR CONTROL DURING BAREFOOT RUNNING: A METHODOLOGICAL AND EXPERIMENTAL APPROACH

EKIZOS, A., SANTUZ, A., ARAMPATZIS, A.

Humboldt-Universität zu Berlin

Introduction Barefoot running has been previously associated to injury risk and performance (Liebermann et al., 2010). Furthermore it is well known that about 50% of rearfoot runners change in midfoot or forefoot strike patterns if they run barefoot (Santuz et al., 2015). These acute non familiar changes from shod to barefoot condition may challenge the neuromuscular system affecting the dynamic control of running stability. The maximal Lyapunov exponent (LyE) which quantifies how the system's states respond to very small perturbations, has been often used to assess neuromuscular control during gait (Dingwell and Cusumano, 2000; Hoogkamer et al., 2015). We completed a twofold experimental approach aiming (a) to examine the reliability of LyE during running using a cluster of trunk markers and (b) to investigate the dynamic stability of runners on shod and barefoot conditions. Methods Twenty healthy participants who run at their preferred speed (2.87 ± 0.42 m/s) on a pressure-plate equipped treadmill were engaged in the study. To examine the reliability of the LyE the participants conducted two-minute running trials; two trials per day for three consecutive days, which were considered as one block. The whole task was then repeated after a minimum of one week apart, namely a second block. To address the effects of barefoot condition on running stability we examined two additional barefoot trials on the first day of the second block. The LyE has been calculated on the vertical axis for eleven markers on the back, individually and in clusters. Results The ICCs within the same day, between the days and between the blocks ranged from 0.7 to 0.9. We did not find a day or block effect in the comparison of the resulting LyE. Markers on the spine provided the most reliable results. Further we found a significantly higher LyE values ($p < 0.05$) in the barefoot compared to shod running. Discussion Our findings provide evidence for an acceptable and specific to used markers reliability in LyE during running. Furthermore the increased LyE in the barefoot running indicates deficits in the neuromuscular control of stability compared to the shod condition that may affect injury risks and running performance. BENEFITS OF HABITUAL BAREFOOT LOCOMOTION – A SYSTEMATIC REVIEW

HOLLANDER, K.1, HEIDT, C.2, VAN DER ZWAARD, B.3, BRAUMANN, K.1, ZECH, A.4

1: University of Hamburg (Germany), 2: University of Zurich (Switzerland), 3: Stellenbosch University (South Africa), 4: Friedrich Schiller University Jena (Germany)

Introduction Little is known about the differences of long-term habitual barefoot (HB) and shod (HS) locomotion. The aim of this study was to systematically review the literature for comparisons of HB and HS populations, and to synthesize the effects of HB locomotion on performance, biomechanics, pathologies and the foot. Methods Following the PRISMA guidelines, a literature search was performed comprising Web of Science, MEDLINE, EMBASE and Cochrane databases. Study inclusion criteria were peer-reviewed published investigations of HB and HS participants. Two researchers independently reviewed selected studies, evaluated quality and level of evidence. A consensus meeting with all authors was performed, if consent was not achieved. Results Of initially found 2535 studies, a total of 15 studies were included. Six studies investigated foot morphology and biomechanics. Three studies considered foot arch and respectively one study discussed injuries and foot diseases. No study investigated motor performance outcomes. Pooled results of HB populations show limited evidence for reduced ankle dorsiflexion at footstrike (pooled effect size -3.47 (95% CI -5.18 to -1.76)) and hallux angle (-1.16 (95% CI -1.64 to -0.68)), as well as shorter (-0.20 (95% CI -0.33 to -0.07)) and wider (0.55 (95% CI 0.06 to 1.05)) feet compared to HS populations. Very limited evidence was found for reduced hip flexion, higher peak eversion angles, higher maximal internal rotation angles and dorsal excursion of the metatarsophalangeal joint in HB participants. Furthermore, HB locomotion had a reduced rate of rearfoot strikes, stride length and time, shorter contact time in running with a longer contact time in walking. Conflicting evidence was found for knee angle (-0.25 (95% CI -1.34 to 0.85)). No differences in relative injury rates were found with limited evidence for a different body part distribution of musculoskeletal injuries, more foot diseases and less foot deformities and defects in HB runners. Discussion The analysis suggests that habitual footwear use influences biomechanics and foot morphology as well as injury and foot deformity rates. No evidence was found on motor performance. Despite a large amount of studies investigating short-term effects of barefoot locomotion (Jenkins and Cauthon 2011, Hall et al. 2013), only limited or very limited evidence is known for long-term effects. Our study shall help to guide future research and encourage to perform well-designed prospective studies examining the effects of habitual barefoot locomotion. INFLUENCE OF MINIMALIST FOOTWEAR ON IMPACT ACCELERATIONS DURING RUNNING

PÉREZ-SORIANO, P., IZQUIERDO, M., RIBAS, V., QUERALT, A., LUCAS-CUEVAS, A.G., GIL-CALVO, M., ENCARNACIÓN, A., APARICIO, I.

University of Valencia.

Introduction The scientific interest on the effects of the minimalist shoes on the runners' performance and injury risk has increased unstoppably in the last years. However, the majority of the studies have not controlled if foot strike is altered when measuring impacts accelerations during running. As a result, it is unclear if the alterations of impacts accelerations are a consequence of the minimalist shoes or the type of foot strike. Therefore, the aim of this study was to analyse impact accelerations during running with minimalist and conventional shoes while controlling the athletes' foot strike. Methods Seventeen male runners habituated to run with minimal shoes performed two running tests of 30 minutes at 80% of their individual maximal aerobic speed on a running track. Participants performed one session with own conventional shoes (CS) and the other session with minimal shoes (MS) (drop = 0, midsole < 4mm) in a random order. Impact accelerations were measured for 10 seconds every 5 minutes (5', 10', 15', 20', 25', 30') on the tibia and head. Head and tibial peak acceleration, acceleration magnitude, acceleration rate and shock attenuation were calculated from the acceleration signal. A pressure mat was placed on the running track in order to measure foot strike during running. Results Foot strike remained unaltered between both shoe conditions. Running with minimal shoes increased the tibial acceleration magnitude (CS vs MS: 11.54 (0.94) vs 13.18 (0.75) G; $p = 0.013$), tibial peak acceleration (CS vs MS: 6.80 (0.56) vs 7.96 (0.40) G; $p = 0.025$), tibial rate (CS vs MS: 530.84 (79.11) vs 789.87 (57.09) G/s; $p = 0.012$), head rate (CS vs MS: 75.78 (7.61) vs 123.43 (13.88) G/s; $p < 0.001$) and shock attenuation (CS vs MS: 60.42 (3.78) vs 67.40 (1.69)%; p

= 0.046) compared to running with the conventional shoe. Discussion When foot strike remains unaltered, running with minimal shoes significantly increases impact acceleration parameters compared to running with conventional shoes (Willy & Davis, 2014). Taking into account that elevated peak accelerations and acceleration rates have been associated with the occurrence of stress fractures (Milner et al., 2006), this type of footwear should be used with caution as it may be putting runners at greater risk of overuse injuries. THE EFFECT OF WEARING MASAI BAREFOOT TECHNOLOGY SHOES ON RECOVERY AFTER MARATHON RUNNING

NAKAGAWA, K.1,2,3, INAMI, T.1, YONEDU, T.1, KENMOTSU, Y.1, NARITA, T.4, KAWAKAMI, Y.1, KANOSUE, K.1

1: Waseda University, 2: JSPS, 3: The University of Tokyo, 4: Health Science University

Introduction A fast recovery from post-full marathon fatigue enables to stay good condition for training as well as for daily life. We previously reported that unstable rocker shoes (Masai Barefoot Technology: MBT) can promote fast recovery in the subjective fatigue from marathon running (Nakagawa et al. 2014). However, it was questionnaire study, and not based on objective indexes. The purpose of the present study was to investigate whether MBT shoes can promote recovery from marathon based on muscle damage markers. Methods The 25 university students participated in the study. They were divided into two groups and wore MBT shoes (MBT group, n=11) or ordinary shoes (control group, n=14) from immediately after marathon (42.195 km) for 1 weeks later. Before (Prel), immediately (Post), 1 day (D1), 3 days (D3) and 8 days (D8) after marathon, muscle hardness (ultrasound elastography), isometric muscle force, muscle soreness and subjective fatigue were measured. Number of steps per day in recovery period was also measured. For each index, the difference between post or D1 and D3 or D8 was calculated as the magnitude of recovery. Results There was no statistical group difference in marathon time and number of steps per day in recovery period. The magnitude of recovery of muscle hardness of gastrocnemius, knee extension force and subjective fatigue were significantly higher in the MBT group compared to the control group. Discussion The result of subjective fatigue had similar tendency to that in our previous study. In addition, we found that muscle hardness and force in some muscles recovered faster in the MBT group. It has been reported that electromyographic activities in lower limb muscles including gastrocnemius and RF were higher during standing or walking with wearing the MBT (Nigg et al. 2012). This activity could become an active rest for lower-limb muscles with heavy damages. In conclusion, wearing MBT shoes can be effective for the recovery of muscle hardness and muscle force from marathon-induced damages. References Nakagawa K, Obu T, Kanosue K. (2014). OVERGROUND AND TREADMILL RUNNING DATA COLLECTION METHODS: COMPARISON OF KINETIC VARIABLES ACROSS SHOD CONDITIONS

GREGG, E., BISSAS, A.

Leeds Beckett University

Introduction Over past decades volumes have been written comparing overground (OG) and treadmill (TM) running mechanics (e.g. Riley et al., 2008) with only a few studies investigating differences in kinetics between the two modes. These studies have generally focussed on running performance (Kluitenberg et al., 2012), however, there is a lack of studies investigating the degree of agreement between OG and TM in terms of impact variables pertinent to shock absorption and orthosis prescription. This study investigated the agreement between OG and instrumented TM data collection methods for measuring kinetic variables during running across a range of shod conditions including barefoot. Methods Vertical ground reaction force data (1000 Hz) were collected from both lower limbs during seven running trials (self-selected speed \pm 5%) conducted on an OG runway with Kistler force platforms embedded within the ground and an instrumented TM (Gaitway, Traunstein). Measurements were taken under three shod conditions: barefoot, shod, and shod with a prefabricated foot orthotic. The data were analysed using two-way repeated measures ANOVAs and a range of agreement statistics including Intraclass Correlation Coefficients (ICC-3,1). Results Whilst a few ICCs showed strong agreement (>0.80), significant interactions revealed that for both feet impact peak force was lower for instrumented TM trials during shod (~13%) and orthotic (~14%) conditions ($p<0.05$), however no significant differences were reported in barefoot trials. Time to impact peak was significantly shorter during OG trials (~10-45ms) compared to TM trials ($p<0.05$) for all three conditions. Active peak forces were significantly reduced during TM trials compared to OG trials for all shod conditions ($p<0.05$), apart from the barefoot trial for the right foot. Finally, contact times were significantly shorter during the OG trials (~25%) for all shod-conditions ($p<0.05$). Discussion This study identified a number of significant differences in multiple kinetic variables between OG and TM data collection methods when analysing running under a number of shod conditions. The data show a trend of more moderate impacts while running on a TM compared to OG especially for shod conditions. This study has many practical implications for practitioners prescribing foot orthoses and researchers working in this field. It is important that practitioners are aware of the potential differences which may be produced when utilising the two different methods, as these differences could lead to incorrect conclusions being drawn, potentially resulting in inappropriate orthosis prescription. INTRA-INDIVIDUAL VARIABILITY IN NOVEL FOOTWEAR ASSOCIATED WITH INJURY IN DISTANCE RUNNERS

AGRESTA, C.E., SOUTHERN, E.M., KESSLER, S.E., GOULET, G.C., ZERNICKE, R.F., DENEWETH, J.M.

University of Michigan

Introduction Evidence surrounding the use of minimalist shoes to reduce incidence of running-related injuries remains inconclusive (Ryan et al.). However, interest in minimalist footwear is high (Rothschild). With no consistent risk factors currently identified for injury, what may be more important is understanding the variables that enable one runner to adapt successfully to a new running shoe while another gets seriously injured. The aim of our study was to examine initial adaptive response to novel footwear, via intra-individual variability, in a shoe with a zero heel-to-toe drop. Methods Thirty experienced, rearfoot-striking runners (15 M; 15 F) who had never worn zero-drop running shoes were enrolled. Subjects ran at 70% VO₂max speed for 10 minutes each in a habitual shoe (HAB), a minimal shoe (MIN; New Balance Minimus), and a maximal shoe (MAX; Altra Paradigm), which were selected for their zero-drop, similar fit, and different midsole thicknesses (11 and 25 mm). Subjects were instrumented with a lower-body inertial measurement system and ran on an instrumented treadmill to collect continuous joint kinematics and vertical ground reaction forces. Runners were randomly assigned MIN or MAX to wear for all runs for four weeks. The amount and structure of variability were calculated by coefficient of variation (CV), standard deviation (SD), and detrended fluctuation analysis (DFA; expressed as α) (Hausdorff et al.), respectively. All variability measures were

normalized to HAB condition and compared via independent t-tests. Results Shoe type was significantly associated with injury with all injuries (7 out of 27) occurring in the group wearing MIN shoes ($p=0.005$). Consequently, subsequent analyses were restricted to this group. Normalized to the HAB shoe, CV was not significant for any spatiotemporal measures. SD demonstrated a trend for stride time ($p=0.09$) with injured runners having increased amount of variability in MIN shoe than uninjured runners. DFA values for MIN condition demonstrated a trend ($p=0.09$) towards lower values in injured ($\alpha=0.97$) compared to uninjured runners ($\alpha=1.17$) in the MIN shoe. Discussion The reduction in structure of variability in injured runners suggests they had reduced flexibility in their gait strategy while running in MIN compared to their HAB shoe, despite displaying a greater amount of variability. A more constrained movement pattern (i.e., a more consistent stride interval) could result in continual loading on the same soft tissue structures leading to overuse and injury. More prospective research is needed to determine the extent to which variability can be used to predict injury, particularly following the transition to novel footwear. References Ryan, M., et al. COULD SKIN TEMPERATURE PREDICT ANKLE EVERSION AFTER RUNNING?

GIL-CALVO, M.1, JIMENEZ-PEREZ, I.1,2, PRIEGO QUESADA, J.I.1,2, LUCAS-CUEVAS, A.G.1, LLANA, S.1, PÉREZ-SORIANO, P.1

University of Valencia

Introduction Ankle eversion is one of the most studied variables in running biomechanics due to its potential relationship with increased injury risk (Hreljac, 2004). Moreover, the assessment of ankle eversion is of great interest for athletes when purchasing footwear. Measuring skin temperature via infrared thermography could be a non-invasive, easy, and quick tool to predict ankle eversion during running. Therefore, the aim of this study was to analyze the relationship between the skin temperature of the plantar surface and ankle eversion during running. Methods Twenty runners (14 males, 6 females) with a neutral-pronated foot contact (7-15° of maximum ankle eversion) participated in the study. Runners carried out a 5-minute maximal aerobic speed test (MAS) (García-Pérez et al, 2014) in order to individualize their laboratory running test. In the laboratory test, participants warmed up for 10 minutes at 60% of their MAS followed by 20 minutes at 80% of their MAS. Skin temperature of 2 Regions Of Interest (ROI's) of the right foot sole (1: Medial foot sole; 2: Lateral foot sole) was measured using infrared thermography (FLIR E60 camera) before (after 10 minutes of thermal adaptation) and after running. Symmetry (difference between medial and lateral ROIs) of absolute values and variation of the skin temperature (difference between after and before running) were assessed. 2D kinematic analysis was performed with two high speed cameras (125 Hz) (MotionScope®) to measure ankle eversion at contact time (ECT) and maximum ankle eversion during stance phase (MAE) of the right foot. Four reflective markers were placed on the lower leg following Clarke et al (1983) model (1: Lower calcaneus; 2: Upper calcaneus; 3: Achilles tendon; 4: Gastrocnemius). Correlations were observed between skin temperature variables and ECT ($p>0.05$ and $r>0.05$). However, there was a positive relationship between the skin temperature variation symmetry and MAE ($r=0.7$ and $p=0.001$; $MAE = 0.1^*skin\ temperature\ variation\ symmetry - 1.3$). Discussion The present study has investigated the relation between skin temperature of the right foot sole and the ankle eversion of runners. The lack of correlation found between ECT and the variation of skin temperature of the feet soles suggested that this kinematic variable had no influence on skin temperature. However, the positive correlation between MAE and skin temperature variation symmetry, showed the potential of the infrared thermography to predict the type of foot contact during running. However, further research looking at runners with different foot type motion is necessary to corroborate these findings. References Clarke TE et al. (1983). Med Sci Sports Exerc, 15(5), 376-381. MO-SH01 Coaching & Talent Monitoring

ELITE KENDO PLAYER EXHIBITS A HIGHER EXECUTIVE FUNCTION

MAEDA, Y., SUWABE, K., FUKUIE, T., HYODO, K., OCHI, G., JESMIN, S., SOYA, H.

university of tsukuba

Introduction Talent identification and development in open skill sports should be based on not only physical functions but also executive functions (e.g. shifting, inhibition and updating). Kendo (Japanese fencing) is a traditional Japanese martial art where two players fight using bamboo swords. Since several studies have demonstrated that experienced fencers have enhanced executive functions with inhibitory response compared to non-athlete (e.g. Taddei et al., MSSE, 2012), executive functions should be important for exhibiting high performance in kendo. It is, however, still unclear the extent to which executive function is enhanced and the role it plays in exceptional elite fencing/kendo players compared to sub-elite, and which type of executive functions is specifically enhanced. Thus, here we addressed these issues by examining the executive functions of elite-Japanese kendo players, including a World champion, and teased-out the relationship between kendo performance and executive function. Method Twenty nine young, healthy male kendo players were divided into elite (n=16) and sub-elite (n=13) groups, based on their performance in a kendo club competition at the University of Tsukuba. All players performed 6 cognitive tasks (shifting, inhibition, and updating each by 2 tasks). Shifting task used color and shape task switching paradigm (C/S-TSP) and letter and digit task switching paradigm (L/D-TSP); inhibition task used flanker task (FT) and Stroop color-word task (SCWT); while updating task used spatial working memory task (SWMT) and verbal working memory task (VWMT). TSP consisted of three different inter-trial interval (50, 650, 1250 ms). Switch cost (reaction time delay between switch trials and non-switch trials) was calculated as an indicator of shifting ability. Results The switch cost of L/D-TSP (shifting) at the shortest interval (50 ms) was significantly lower in the elite group compared to the sub-elite group (paired t-test; $p<0.01$). However, no difference was noted in the other two longer inter-trial intervals (650 ms, 1250 ms), and no significant difference was observed in C/S-TSP (shifting), FT (inhibition), CWT (inhibition), SWMT (updating), as well as VWMT (updating) between the two groups (elite vs. -elite). Discussion The present study is the first to demonstrate that elite kendo players have outstanding shifting capabilities under high-speed conditions. This may be due to the fact that kendo players need to continuously evaluate the situation of the game or shift their mental state (go on offense, defense or wait to make a move) in a dynamically changing, high speed game in order to earn an 'ippon' (valid strike). The findings of the current study has two key

implications in this sports: it reveals the impact of executive cognition in: 1) optimal shifting-based training protocol of kendo players and; 2) recruiting high caliber talent in this global-expanding sports (kendo). Contact hsoya@taiiku.tsukuba.ac.jp

AN ONLINE TRAINING DIARY TO MONITOR ELITE ATHLETES RESPONSE DURING A 21-DAY TRAINING CAMP

BALDASSARRE, R.1, BONIFAZI, M.2,3, MEEUSEN, R.4, PIACENTINI, M.F.1,4

1: University of Rome Foro Italico (Italy), 2: University of Siena (Italy), 3: Italian Swimming Federation, 4: Vrije Universiteit Brussel (Belgium)

INTRODUCTION Best competition performances in endurance sports are often achieved following a taper phase, which is typically completed after periods of heavy training or training camps (TC) (Aubry et al. 2014). This deliberate overload period may or may not bring to functional overreaching (FO) and recently it has been shown that performance gains were better achieved after an overload period without the presence of FO (Aubry et al. 2014). Therefore, the aim of the present study was to determine if FO is necessary to improve performance in elite open-water athletes. **METHODS** Eight elite open-water swimmers (3 male and 5 female; 24.2±6.1 yrs) participated in the study and were followed during a 21-day TC and a 7-day taper by means of an online training diary (www.spartanova.com), and a weekly profile of mood state. The diary includes both objective and subjective data reported on a 10 cm visual analogue scale. Based on their individual response, according to previous literature (Piacentini et al. 2015), athletes were divided in a FO group and acute fatigue group (AF). Changes in training volume (TV), session RPE (sRPE) (RPExmin) and Total Mood (TM=depression+fatigue+tension+anger-vigour) during the TC were compared using Friedman's ANOVA test ($p<0.05$). **RESULTS** Five athletes showed signs of FO and 3 of AF. Despite a similar significant increase in TV during the TC (34%-wk1, 47%-wk2, 12%-wk3; 2(4)=22.20 $p<0.000$), sRPE showed a different trend, increasing more in the FO group (52%-wk1, 81%-wk2, 7%-wk3; 2(4)=16.00 $p=0.003$); TM did not change significantly in either group, however it increased by 49% at the end of the TC in the FO group while it decreased by 33% in the AF. After the TC, athletes tapered (TV reduction of 60%) and a subgroup of 4 athletes competed in a 10-km race, winning three medals and 1 personal best. Two of the athletes were in the FO group and 2 in the AF. **DISCUSSION** Athletes showed a different response to the TC. Five athletes showed mood disturbances and an increase in the OR signal and were considered FO (Piacentini et al. 2015), but restored all parameters after 1 wk of tapering. Two athletes in this group won a medal in the world cup race. Other 3 athletes showed modest signs of FO and improved their overall mood during the training camp. However, 2 from the AF achieved a medal and a personal best during the 10-km open water competition, confirming that each athlete must be monitored and treated as an individual, despite similar training workloads. **REFERENCES** Aubry et al. IS PERFORMANCE AT YOUNG AGE A GOOD PREDICTOR OF LATER SUCCESS?

PINGWEI, L., DE BOSSCHER, V.

Vrije Universiteit Brussel

Introduction Most countries attempt to develop systematic structures to identify gifted talented athletes and to promote their development in certain sports. However, forecasting years in advance for the next generation of sport experts is challenging. The aim of this study is to facilitate talent identification and development program by identify a critical age at which athletes should start to perform in international competitions, and to what extent it is reliable to use junior success as a criterion to predict senior success. **Methods** The preliminary research consists of a European analysis of four sports: judo, tennis, gymnastics and athletics. This case study uses a top down approach to collect data in answering the question: how did senior elite athletes performed during youth tournaments? The sport specific principles were chosen in consultation with representatives of the Flemish Sport Federations. We focused first on correlations between performances on youth tournaments and professional level. Second, we shed light on how elite athletes performed in the selected youth tournaments (top down approach). **Results** The conducted correlations were all significant but ranged from very weak-to-weak correlations. As a result, junior athletes with better performances at the selected youth tournaments appear to have a slightly greater chance to be successful at the elite athlete level. Secondly, we conclude that there is an uncertainty about the relationship of performances on youth tournaments and success of elite athletes. The result also reveals that a third of all world-class athletes for athletics, judo as well as gymnastics did not perform or participate in the selected youth tournaments. **Discussion** These results indicate the general good to put into perspective the relative importance of performances at young ages. Moreover, a mixture of physical and mental skills into appropriate action is common for all sports and each sport is marked by a singularity of required sport-specific elements for successful performance (Baker & Horton, 2004). The ages at which transitions occur as well as the duration of the stages are sport-specific (Wylleman, Alfermann, & Lavallee, 2004). Therefore, it should be indicated that the youth performance sports index is only one out of many parameters evaluating the development of young athletes. Reference Abbott, A., & Collins, D. COMPARATIVE ANTHROPOMETRIC AND PHYSICAL CHARACTERISTICS OF YOUTH FOOTBALL PLAYERS AT THE VARIOUS STAGES OF AN INTERNATIONAL FOOTBALL TALENT SCREENING AND SELECTION PROGRAM.

PRICE, A., PELTOLA, E., VARAMENTI, E., BOURDON, P., CABLE, T.

Aspire Academy

Introduction: This study compares the baseline anthropometric and physical performance characteristics of youth football players at the various levels of a four-stage international humanitarian football talent screening and selection project (Aspire Football Dreams) which aims to inspire hope in children in developing countries. Over the past 9 years, ~4.6 million boys from 19 developing countries across Africa, Asia and Latin America have registered for the project. This study includes data from the first 4 years of the project (2007-2010) as it takes a minimum 4 years to progress to Stage 4. **Methods:** Players were categorised based on the highest selection stage they achieved; Stage 1 - Country Finals (n=1823), Stage 2 - World Finals (n=49), Stage 3 – Educational and Sports Development Scholarship (n=64), Stage 4 -Professional Contract (n=20). Player progression was decided by a panel of coaches/staff based on a myriad of factors including technical, tactical, physical, psychological measures and predicted future potential. Only a limited number of players progress at any stage and they could opt to drop out at any time. Minimum age to progress to Stage 4 is 18 years old. Three anthropometric (height, seated height and body mass) and three physical performance measures (counter movement jump (CMJ) using a KMS jump mat, 40 m sprint with 10 m splits to assess peak velocity (m/s) using an electronic timing gate system, and a 20 metre multi stage shuttle run test) were assessed on all players during Stage 1. These measures were used for all subsequent analyses. **Results:** ANOVA analysis showed

that players that progressed to Stage 3 were significantly ($p \leq 0.05$); taller (167.5 vs. 171.1 cm), heavier (55.8 vs. 59.0 kg), faster (40 m sprint – 5.67 vs. 5.43 s), more powerful (CMJ – 37.1 vs. 39.9 cm) and displayed greater endurance (20 m Shuttle score – 11.55 vs. 12.45 level) than those players who did not progress beyond Stage 1. Those players selected to Stage 4 failed to show any significant differences from the other stages which is likely due to the relatively low number of players (n=20) progressing to this stage. Conclusion: These results suggest anthropometric and physical performance characteristics play an important role in the earlier stages of the selection program (Stages 1 to 3). However when it comes to the selection of players for a professional contract at Stage 4, other non-physical measures (i.e., technical skills, tactical understanding, personality, attitude etc.) become equally if not more important. NOVEL METHOD FOR ASSESSMENT OF DURABILITY OF SAILING PROTECTIVE GARMENTS IN SIMULATED ENVIRONMENTS

WATSON, C.

RMIT University

Competitive sailing is one of the extreme sports which is performed at high speeds in challenging weather and environmental conditions with strenuous physical demands placed on the athlete. Sailing garments need to satisfy numerous performance requirements, such as being ergonomically and thermo physiologically comfortable, highly aerodynamic, light weight, protect from UV radiation and the elements, and most importantly be strong to withstand constant abrasion and flexing but also with durability to withstand these rigours over the life of the garment. The fabrics and materials comprising these garments must remain waterproof after dynamic three-dimensional abrasion, multi-directional impact and extended wear and tear both in dry and especially wet conditions. Any leaks in these garments are generally considered a fail by most sailors and the garment would then to be replaced. Standard bench top tests exist for testing the materials for such attributes as abrasion resistance, puncture and tear resistance, generally separately for each attribute. In addition standardised hydrostatic head testing is common; however it does not give any indication as to how the fabric or material will perform in protecting the athlete after extended periods of use, especially in wet conditions. Waterproofing and breathability are two selected critical attributes that were addressed in the present study. Suitable novel experimental methodology, instrumentation and methods were developed to assess durability of these attributes for a number of materials containing breathable membranes, after prolonged simulated use in wet conditions. Results clearly indicate that the performance of the materials intended for sailing apparel must be considered not only as separate attributes in dry conditions but also in combination in dynamic wet conditions.

VALIDITY AND RELIABILITY OF A NEW 16 HZ GLOBAL POSITIONING SYSTEM.

PEETERS, A.

French Rugby Union

Introduction Recently, studies reported that training load monitoring and the appropriately graded prescription of high training loads should improve players' fitness, which in turn may protect against injury (Gabbett 2016). In elite team sports, most of the sports scientist use Global positioning systems (GPS) to quantify training loads but some limitations have been raised concerning validity and reliability of GPS for measuring high-velocity activities and accelerations. Thus, the aim of this study was to assess the validity and reliability of a new 16 Hz GPS. Méthods Six Sensoreverywhere V2 GPS units (Digital simulation, Paris, France) were attached to a custom-made steel sled and pushed by an athlete performing linear 60-m run at four various constant speed (1.00 ± 0.02 , 2.00 ± 0.11 , 3.8 ± 0.17 and 6.11 ± 0.8 m.s $^{-1}$). Velocity was measured with 4 timings gates placed from 20-m to 40-m, separated by 5-m to ensure that speed was kept constant by the athlete. In order to assess maximal speed and acceleration, a radar was also placed at the start of the track for the sprinting condition. Results. There was a trivial bias between velocity measured with the GPS and the timing gates ($0.11, \pm 0.04$ m.s $^{-1}$) and a trivial Typical Error of Measurement (TEM, $0.04, \pm 0.01$ m.s $^{-1}$ 90% confidence intervals). There was a low between-units TEM over the various constant speed tested ($0.01, \pm 0.01$ to $0.04, \pm 0.04$ m.s $^{-1}$ and $0.5, \pm 0.15$ to $0.6, \pm 0.35$ % from walk to sprint respectively). Furthermore, assessment of both maximal speed and acceleration recorded during the sprint condition showed trivial between-units TEM (respectively $0.06, \pm 0.03$ % and $3.1, \pm 6.4$ %). Conclusion This study was the first to analyze the validity and reliability of the Sensoreverywhere V2 16Hz GPS units. The results report low bias level and TEM confirming the validity of 16 Hz GPS for measuring speed over a range of velocities. Furthermore, high level of reliability have been reported in this study, confirming that increased sampling frequency seems to overcome limitations suggested concerning both high-velocity and acceleration monitoring in athletes (Scott et al. 2015). Therefore, 16 Hz GPS technology could be used to monitor training loads in team sports teams and seems to offer alternatives for the assessment of maximal speed and/or acceleration. Gabbett, T.J., 2016. The training-injury prevention paradox: should athletes be training smarter and harder? British journal of sports medicine. Scott, M.T.U., Scott, T.J.U. & Kelly, V.G., 2015. The validity and Reliability of Global Positioning Systems In Team Sport: A Brief Review. The Journal of Strength & Conditioning Research.

ATTITUDE TOWARDS CONFLICT SITUATIONS IN A HANDBALL TEAM AMONG COACHES

BON, M., BILGE, M.

University of Ljubljana, Faculty of Sport

The aim of the study was to ascertain the attitude of handball coaches towards conflict situations with regard to selected socio-demographic characteristics. The sample consisted of 58 Slovenian handball coaches working in youth teams. Many differences were discovered between groups of participants. Female coaches held a higher degree of education compared to their male colleagues, and more of them were single (all younger than 31 years). More than half of all participants are involved in an emotional relationship and have children of their own. Generally speaking, coaches have a relatively neutral attitude towards conflicts; they admit their presence, but do not always act as to prevent them from happening. They do not immediately exclude a conflictive player from the team, but try to influence her/him. A conflict with the players or the team management does not divert them from their activity. Female coaches are "more tolerant" of conflicts in their team and seldom intervene between players. Older coaches tend to choose extreme statements. They admit the presence of conflicts, but do not seek reasons for them, often leaving the players to settle the conflict by themselves. Coaches involved in an emotional relationship are slightly more "tolerant" of conflicts. Less experienced coaches perceive conflicts as "less useful" compared to more experienced coaches, while professional coaches agree to a greater extent that conflicts must always be solved. Higher educated coaches tend to notice more conflicts, which probably comes as a consequence of their greater self-criticality. They more frequently see positive sides of conflicts and try to discover the causes for conflict arise.

JUDO COACHES' VISUAL SEARCH STRATEGIES FROM "HAJIME" TO FIRST CONTACT

ROBERTSON, P.J., NEVISON, C., CALLAN, M., TIMMIS, M.A.

Anglia Ruskin University, Cambridge, UK

Introduction Athletes' visual search strategies are dependent upon ability and task demands. Yet, there is limited research into coaches' visual search strategies, and no understanding of judo coaches' visual search strategies when observing fights. The current research investigated judo coaches' visual search strategies from the beginning of fights to the first contact between athletes. Methods Twenty qualified coaches viewed footage of fights recorded from a position adjacent to the coach's chair at an international event. Judo athletes compete wearing white or blue judogi, and coaches were instructed to coach the athlete wearing white in all fights. Coaches' eye movements were recorded with SensoMotoric Instruments (SMI) Eye Tracking Glasses. Eye movements were mapped frame-by-frame to areas of interest (AOIs) using SMI BeGaze software. Results Significantly more time was spent fixating on the athletes in comparison to the referee, scoreboard, and irrelevant areas ($p<0.02$). There was no significant difference between time spent fixating on each athlete, or time spent fixating on the athletes and the space between them. Time spent fixating on the space between the athletes was significantly greater than that spent on the referee and irrelevant areas ($p<0.02$). There were a greater number of fixations on the athletes compared to the referee, scoreboard, and irrelevant areas ($p<0.002$). There was no significant difference in the number of fixations on each athlete, or in the number of fixations on the athletes and the space between them. The number of fixations on the space between the athletes was greater than those on the referee and irrelevant areas ($p<0.007$). Discussion Coaches fixated more frequently and for longer on the athletes and the space between them. No significant difference between fixation frequency and duration between athletes and the space between them suggests that the space and the athletes are of comparable importance to the coach. Research suggests that central areas act as anchors for visual search, with peripheral vision obtaining information from other areas (e.g., Milazzo et al., 2015; Piras et al., 2014). Results from the current study suggest that judo coaches may utilise the space between the athletes as an anchor for their visual search. Future research should investigate the pattern of visual search to better understand how coaches use this space. References Milazzo, N. et al. (2015). MODELLING BATTING EXPERTISE FROM THE PERSPECTIVE OF HIGH PERFORMANCE COACHES

CONNOR, J.D., RENSHAW, I., FARROW, D., ABERNETHY, B.

Victoria University

Cricket coaching literature on developing batting expertise has largely focused on the individual, and typically, technical features of batting. Research in cricket batting has addressed developmental factors of expertise (Weissensteiner, et al., 2009) or the perceptual advantage of expert batters (Muller & Abernethy, 2006). Little attention has been paid to the importance of the individual-environment relationship in expert behaviour. In order to address this missing ingredient, one on one, in-depth, semi-structured interviews were undertaken by the primary researcher with eight high performance coaches (e.g., international or state) who were purposively sampled from Cricket Australia or State Cricket associations. Six of these coaches had played international cricket as batsmen, one played state level and one a first grade player. Interviews were transcribed verbatim and coded separately by the first and second author after each interview. The third author then reviewed all codes and provided feedback. Strategies used to enhance validity included; sampling coaches of different high performance levels and retrospective member checking with coaches. Key themes that emerged include expert's superior knowledge of, and attunement to internal (e.g., emotions) and external (e.g. pitch type, field settings) information. This informs their intentions, perceptions and actions to achieve the task goal at any game moment. A skilful batter has time to execute their action and is in 'rhythm' with the bowler through attunement to specifying information sources. Experts also adapt to and manipulate the performance environment. Self-evaluative processes, through between-ball routines provide opportunity to reflect, re-evaluate and plan for the next delivery. Examples include; changing stance, forcing field changes or manipulating bowler's emotions. These results highlight the importance of capturing the experiential knowledge of high performance coaches that cannot be obtained through traditional laboratory based studies. For cricket batting coaches, this work emphasizes the importance of designing learning environments that enable players to better understand their own performance in the context of emergent dynamic game-based constraints. ACTIVITY PROFILES AND FATIGUE IN INTERNATIONAL FEMALE TEAM HANDBALL USING PLAYER LOAD™

WIK, E.H., LUTEBERGET, L.S., SPENCER, M.

Norwegian School of Sport Sciences

Introduction Handball matches place diverse physical demands on players, which may result in fatigue and decreased activity levels. However, previous speed-based methods of quantifying player activity may not be sensitive for capturing short-lasting handball-specific movements. Therefore, the aim was to examine activity profiles of a female handball team and individual player profiles, using inertial measurement units (IMUs). Development of fatigue, indicated by temporal or transient declines in activity, was of special interest. Methods Match data was obtained from one female national team in nine international matches ($n=85$ individual player files), using the Catapult OptimEye S5 (Catapult Sports, Australia). Player Load™/min, an accelerometer-derived measure of intensity, was analyzed for 5- and 10-min periods. Team activity levels represent intensity of the players on the field in the given period (minimum one-min field time), and are presented as a percentage of their match average. Individual player activity levels are based on periods with a minimum of 60% field time, and are expressed as a percentage of their average in these 5-min periods. Magnitude based inferences were used to de-

scribe probabilities of substantial differences between single or pooled periods. Results A high initial intensity was observed for team profiles (110% of match mean), and for players with 2 or more consecutive periods of play (107% of 5-min mean). Substantial declines in Player Load™/min were observed throughout matches for the team (91% of match mean in the least intense period), and for players with several consecutive periods of field time (90% of 5-min mean in the seventh period). Intensity increased substantially in the final five min of the first half for team profiles, and the first ten min of the second half were substantially lower than the corresponding first half period. Activity levels were substantially lower in the five min after a player's most intense period, and were partly restored in the subsequent 5-min period. Conclusions Declines as observed in activity profiles for the team and individual players may be indicative of temporal and transient fatigue during handball matches. Underlying mechanisms were not accounted for, yet situational factors and pacing strategies are suggested as possible contributing factors, based on previous team-sport studies. DEFENSIVE BALANCE IN ELITE FOOTBALL: MAKING RELIABLE OBSERVATIONS

SCHULZE, E., MEYER, T.

Saarland University

Introduction It has been found that teams show anti-phase coordination during goal-scoring opportunities in elite football (soccer; Moura et al., 2016). These contrasting movements can be interpreted as a perturbation of the defensive team's balance in relation to the offensive one. The concept of defensive balance has been introduced before and deemed crucial for the efficacy of playing styles (Tenga et al., 2010). The aim of this study was to determine the reliability of expert observations of defensive balance to possibly extract patterns within successful attacking sequences. Methods Ten performance analysts, coaches, and scouts (7 ± 5 years of experience with match analysis) analysed five clips involving goal-scoring opportunities in matches between different elite international teams in a randomised order. The defensive balance within the defending team was rated in 1s-intervals on a 5-point scale. A slope of every four consecutive log-transformed ratings was calculated to determine the time window where defensive balance was disturbed most strongly (SLP). After every clip, participants also had to indicate which second they deemed decisive during the attacking sequence (SEC). Agreement was calculated as the percentage of ratings corresponding to the mode, the most reported rating for one variable, and statistically tested with a paired samples T-test. Results Ratings of defensive balance in 1s-intervals agreed by $58.2 \pm 3.8\%$ between participants. The conversion of these ratings led to an agreement of $52.0 \pm 23.9\%$ for SLP. A tendency towards a significantly higher agreement was found compared to SEC ($36.0 \pm 11.4\%$; $P=0.08$). By including those ratings within 1s of the mode, the agreement of SLP and SEC increased to $70.0 \pm 14.1\%$ and $50.0 \pm 18.7\%$, respectively. This allowance did not significantly change the agreement within methods ($P=0.07$ & $P=0.14$), however the agreement within SLP was significantly higher than that within SEC after allowing for a 1s-variance ($P=0.05$). Discussion The method that used the second-by-second ratings of defensive balance and transformed those into a slope describing the change in balance over a 4s-window (SLP), proved to be more reliable when allowing a 1s-deviation from the mode compared to a self-selected time frame (SEC). This shows that the concept of defensive balance requires more than merely subjective ratings of experts. The strong agreement within SLP could enable indicating what player actions are most detrimental to a team's defensive balance. This might provide useful information towards improving team performance and the quality of opposition scouting. PRESEASON INTERNAL AND EXTERNAL LOAD OF A PROFESSIONAL BASKETBALL TEAM

MORENO, D., PEÑA, X., BUSCÀ, B.

Club Joventut de Badalona

Introduction Training load calculation has become an important topic in team sports to design better training schedules and to achieve a better performance, while avoiding overtraining and injuries. Internal and external loads are necessary to describe both, the structure of the game or practice and the effect caused by that load over the players (Wallace et al. 2014). Our work combined different methods to assess load dynamics during the six weeks of the preseason of a professional basketball team. Methods Six professional basketball players participated in the study. Rate of perceived exertion (RPE), heart rate variability (HRV), modified summated heart rate zones (mSHRZ), overall distance covered (LOAD), high intensity efforts (HIE) and HIE to active time ratio (HIEr) were registered during the six pre-season weeks of a Spanish professional basketball team. Two practices, consisting in weight lifting and shootaround, were not considered in the study. Results HRV and RPE internal load markers showed a large negative correlation ($r = -0.80$) while in-session internal mSHRZ and external HIEr showed also a large but positive correlation ($r = 0.52$), according to Cohen's convention. Both LOAD and HIE increased throughout the preseason period. Discussion Although some relations have been found between internal and external load markers, it is common to observe that those parameters progress in different ways (Scanlan et al. 2014). Internal off-session load markers had a good agreement while seemed not to be well correlated with external load markers, more than probably due to the quality and quantity of the resting period and because physical improvements were not taken into account (Wallace et al., 2014). LOAD and HIE and their ratio (HIEr/LOAD) increased during the preseason, especially during the last three weeks of the period, as observed in some other works. Internal and external load seem to give different information that must be taken into account to improve training design (Manzi et al., 2010; Scanlan et al., 2014). REPEATED-SPRINT RUNNING IN HYPOXIA ALTERS COGNITIVE FUNCTION IN TEAM-SPORT ATHLETES

MORRISON, J.1, MACDONALD, L.1,2, MINAHAN, C.1

1. Griffith University, 2. Queensland Academy of Sport.

Introduction Repeated-sprint training in hypoxia (RSH) further improves repeated-sprint ability compared with training in normoxia (RSN; Faiss et al. 2013). Although these findings suggest that RSH is valuable for team-sport athletes, further research is required to ensure that there are no undesirable effects associated with RSH. For example, Li et al. (2000) demonstrated that 1 h of passive exposure to altitude can impact cognitive function which may predispose athletes to reduced neuromuscular control and risk of injury (Swanik et al. 2007). The purpose of this study was to determine the effects of RSH on cognitive performance in team-sport athletes. Methods Male team-sport athletes ($n=12$, 24 (5) yr) performed a computer-based cognitive test battery assessing choice reaction time (identification task; IDN) and spatial memory (one card learning task; OCL) before and after repeated-sprint running (4 sets x 4, 4-s sprints; i.e., RSR444). Subjects performed the RSR444 on a non-motorized treadmill in normobaric normoxia (20.9%O₂) and hypoxia (14.5%O₂). Results Peak speed and distance achieved during Set 1 and Set 2 of the RSR444 were not different between conditions ($p>0.05$). However, both peak speed and distance achieved during Set 3 and Set 4 were lower in hypoxia compared with normoxia ($p<0.05$). Mean SpO₂ was 94.5(1.8)% in normoxia and 79.4 (4.0)% in hypoxia after the RSR444. There were no differences in the mean reaction time (RT) for the IDN ($p=0.34$) or the OCL accuracy score ($p=0.49$) before the RSR444 between the two conditions. After the RSR444, no changes were observed in RT for the IDN in either normoxia ($p=0.55$) or hypoxia ($p=0.18$). The OCL accuracy score did not change after the RSR444 in normoxia ($p=0.54$) but accuracy was lower after the RSR444 in hypoxia ($p=0.03$). Discussion The findings of the present study demonstrate that simple cognitive tasks (i.e., IDN) are not affected by repeated-sprint running in either normoxic or hypoxic environments. In contrast, repeated-sprint running decreases performance of complex cognitive tasks (i.e., OCL accuracy) when performed in hypoxia but not normoxia. Given the negative relationship between cognitive function and noncontact lower-limb injury in athletes (Swanik et al. 2007) coaches should be considerate of the effects of hypoxia on cognitive function when prescribing RSH. BALANCE CONTROL UNDER PHYSICAL LOAD AT YOUTH ELITE SOCCER PLAYERS

PORTELA, J., HARTMANN, U.

University Leipzig - Faculty of Sport Science

Introduction Balance control (BC) plays a decisive role in the realisation of soccer-specific skills (Chew-Bullock et al., 2012; Béraud & Gahéry, 1997). Fatiguing exercise can impair BC (Douris et al., 2011). Hence, it is aim of the quasi-experimental study to investigate, how BC is influenced by increasing load. Methods Male youth elite soccer players, separated in load group (L; $n=15$; 13.5 ± 0.1 y, 50.6 ± 1.8 kg, 165 ± 2 cm) and in control (C; $n=11$; 14.1 ± 0.2 y, 45.8 ± 2.6 kg, 158 ± 3 cm) previously performed a physical test to determine the heart rate(HR)max . The L carried out a stepwise incremental running protocol (starting with 7.2 km/h by 1.4 km/h increase every 5 min until volitional exhaustion). After the warm-up and between each 5 min load, a balance test (BT) was performed. The C performed the BT after the warm-up and 6 times every 5 min in rest conditions. Posturographic data were collected by means of BT for 32 s, first with preferred and then with non-preferred leg on a swinging platform (Posturomed, Haider Bioswing®, GER) under standardised conditions (Bruhn et al., 2001). The mean acceleration of both legs (am) were calculated and subsequently analysed. Three-five months later, the L repeated test series. HR in both group; blood lactate (BL) and oxygen consumption (O₂) were measured in L. ANOVA with repeated measures was used. Results HR-values of the C after warm-up were 115 ± 14 bpm ($57\pm6\%$ HRmax) and in average for rest conditions 100 ± 11 bpm ($50\pm5\%$ HRmax). In contrast, HR-values of the L progressively ascended and achieved 193 ± 8 bpm ($100\pm3\%$ HRmax) in the exhausting load. Maximal BL and O₂ were 6.0 ± 1.7 mmol/l and 2.9 ± 0.5 l/min ($94\pm5\%$ O₂max). The C constantly improved am-values from 15.6 ± 5.6 mm/s² (warm-up) to 5.5 ± 1.0 mm/s² (last try). The L improved BC from 8.8 ± 3.7 mm/s² (warm-up) to 7.1 ± 2.5 mm/s² (penultimate try). However, after the exhaustion step deteriorated a little am-values 7.2 ± 2.5 mm/s². Same behaviour could be held in the second test series. Discussion Youth soccer players show compensatory skills to maintain BC under stress conditions. Only under very exhausting loads they were not able to sustain the quality of BC. Results of the study could be used for training methodology of technique and coordination skills. MODELING LONGITUDINAL CHANGES IN ISOKINETIC AND ISOMETRIC STRENGTH OF THE KNEE IN ADOLESCENT SOCCER PLAYERS

DUARTE, J.P.1, PHILIPPAERTS, R.2, VALENTE-DOS-SANTOS, J.1, SEABRA, A.3, COELHO-E-SILVA, M.J.1, MALINA, R.M.4

University of Coimbra, Portugal

1: UC (Coimbra, Portugal), 2: UC (Ghent, Belgium), 3: UP (Porto, Portugal), 4: UT (Texas, EUA) Introduction This study examined the contributions of growth, estimated body composition and skeletal maturity to developmental changes in isometric and isokinetic strength of the knee extensors and flexors in a mixed-longitudinal sample of youth soccer players. Methods 67 Belgian players with chronological ages (CA) 10.5 to 13.6 years at baseline were followed on three to five occasions over five years. Stature, body mass, skinfold thicknesses, isometric strength of the knee extensors (ImKE) and knee flexors (ImKF), and isokinetic knee extension (IsoKE) and flexion (IsoKF) using a concentric protocol (180°/s) were measured. Skinfolds were used to predict % of fat; fat mass (FM) and fat-free mass (FFM) derived. Skeletal age (SA) was estimated with the TW2 RUS method. Multilevel random effects regression analyses were used to derive developmental polynomial models (MLwiN 2.02). Results In four significant longitudinal models, an increase of 1 year in chronological age predicted 10.7N (ImKE), 2.7N (ImKF), 5.4N.m (IsoKE) and 2.7N.m (IsoKF), respectively. A gain of 1 kg of FM corresponded to an increment of 1.4N in ImKE, while a gain of 1 kg of FFM corresponded to an increase of 2.1N (ImKF), 1.4N.m(IsoKE) and 1.6 N.m (IsoKF). An SA classified as average (on time) or advanced (early) corresponded to advantage of 5.2N or 6.5N in ImKE, respectively. Discussion The different knee strength outputs had distinct developmental models across adolescence, but CA and CA squared were predictors in three of the four measures. SA contributed to longitudinal changes in isometric extensor strength, while body composition, especially FM, contributed to longitudinal changes in dynamic strength protocols. The results suggested a potentially important role for allometric multilevel modeling in partitioning effects attributed to indicators of body size, maturity status and training. TRAINING INDUCED CHANGES IN EXTERNAL LOAD ON ACADEMY SOCCER PLAYERS

JORDAN, A., THOMAS, A., WILKIE, B., HARPER, D., LIEFIETH, A., METCALFE, M.

York St. John University

Introduction A combination of GPS and accelerometry data can quantify the external load experienced by an athlete to analyse performance and monitor training load. The aim of this study was to determine the effect of a training intervention on external load and sport-specific fitness in soccer players. Methods Nine Academy soccer players (age 17 ± 1, height 1.76 ± 0.84 m and mass 68.3 ± 7.5 kg) completed a 6-week gym- (2x1 hours per week) and field-based training intervention (2x1 hours per week) with a focus on eccentric and deceleration exercises. Pre and post-intervention measures of anaerobic capacity were determined by a Triple 120 m test (Holloway et al., 2008) modified for soccer players. The modified T120 consisted of 3 bouts of 12 x 10 m shuttle sprints with a chest-to-floor drop and 5 toe-taps on the 1st, 5th and 9th shuttle. Bouts were separated by 1 minute low intensity active recovery. Players wore GPS and accelerometer monitors (Catapult Optimeye S5) during the tests. Time to complete modified T120, average bout time, Player Load (external load) and Player Load/min were calculated (recovery periods excluded from all parameters). Results Paired t-tests identified significant reductions in the time to complete the modified T120 (119.91s to 116.96s, p=0.033), mean time per bout (39.97s to 38.99s, p=0.033) and Player Load (54.4 to 52.6, p=0.045) following the intervention. Discussion The reduced external load is indicative of an improved economy of movement during the modified T120. Potentially, the load associated with accelerating and decelerating during the modified T120, which are physically demanding actions and key determinants of soccer performance (Osgnach et al., 2010), might have been reduced following training. This is likely due to improved damping of ground reaction forces through the lower limb as a result of eccentric training. The reduced external load is particularly interesting given the faster performance of the modified T120 test observed. This is in agreement with Akenhead et al., (2013) who previously observed reduced PL at constant pace following training. This study provides a basis for assessing external load alongside variations in physical performance and internal load. References Akenhead, R., Hayes, P.R., Thompson, K.G. and French, D. (2013). THE IMPACT OF YOUTH SOCCER TRAINING & MATCH-PLAY ON THE HABITUAL SLEEPING PATTERN OF YOUTH SOCCER PLAYERS.

TURNER, C.1, MUIR, I.2, GREGSON, W.1, DI MICHELE, R.3, DRUST, B.1

1: Liverpool John Moores University, 2: Nike, 3: University of Bologna

Introduction Sleep is often regarded as one of the most important recovery strategies available to athletes. It is suggested that the sleep of athletes is sub-optimal. This may relate to factors associated with sports performance that may impact sleep (Leeder, et al, 2012). The current study was designed to investigate the habitual sleeping patterns of youth soccer players and to identify potential factors related to the physical demands of the sport that may affect sleep. Methods Sleep was collected over a 14-day in-season period during the soccer season within the habitual setting of the players. Sleep was detected using a commercially available EEG wireless sleep monitor (Zeo Inc, Newton, MA). Each collected sleep variable; time of lights out (TOLO), time of final awakening (TOFA), sleep onset latency (SOL), total sleep time (TST) and time spent in wake (TWAKE) was compared for a specific day within the training schedule (i.e. match day [MD], the number of days away from the next match MD- 5, MD-4, MD-3, MD-2, MD-1 and recovery days [M+1]) and to training/match load metrics such as total distance (TD) and high-speed distance (>5.5 m/s) (HSD) collected from a GPS system (STATSports Viper, Ltd). The data were analysed using linear mixed models to assess the effects of the schedule and physical load on the sleep variables. Results The youth soccer players displayed an average SOL of 29 ± 23 min, a TST of 462 ± 72 min and TWAKE of 14 ± 2. The TST was lower (~66 min) on the recovery days following the match day (M+1) in comparison to the training days preceding the match (M-1 & M-2) (p < 0.05). SOL and TWAKE were not affected by the type of day in the schedule (p > 0.1). A 100m increase in HSD increased TWAKE by 2 min (0.06 to 3 min, p = 0.0015) and also delayed TOFA by 8 min (3 to 15 min, p = 0.00009). Discussion The youth soccer players attained a sufficient sleep quantity to maintain healthy function (Ferrara & De Gennaro, 2001), though may fall short of the >8 h sleep recommendation for athletes. Sleep loss on designated recovery days following the match day may impact the process of recovery. Our findings indicate an increase in training intensity (HSD) may increase the level of disturbance (TWAKE) each night. References Ferrara, M., & De Gennaro, L. (2001). How much sleep do we need? MO-PM53 Coaching: Training Effects

TRAINING VOLUME IN DIFERENT SPORTS IN FUNCTION SEX AND AGE

SAAVEDRA, J., ÞORGEIRSSON, S., HALLDÓRSSON, K., GUÐMUNDSDÓTTIR, M.L., SIGMUNDSSON, H., KRISTJÁNSDÓTTIR, H.

Reykjavik University

Introduction Training load can be determined by its relationship between training intensity and volume (Laursen, 2010). The volume can be varied in function several aspects: athlete's characteristics, sport, type of periodization, among others. The aim of this study was to analyse the volume of training in several sports in function of sex and age. Methods 302 athletes (male, n=132; female, n=170) of different sports participated in this study (artistic gymnastics, athletics, basketball, beach volleyball, golf, judo, shooting, swimming, table tennis, tennis and volleyball). The athletes were classified by sex, sport and age (younger: 20 years old or under, medians: between 21 and 30

years, older: 31 years old or above). The athletes completed a questionnaire about the training volume and competition. A one-way ANOVA with a Bonferroni post-hoc test was used to establish differences by sex, sport and age group. Results There was no differences between males and females in any item. The younger athletes train more time per week than medians (16.89 ± 4.80 hour vs 15.40 ± 4.92 hour, $p < .001$), who train more time than older athletes (12.87 ± 4.31 hour; $p < .001$). Artistic gymnastic athletes and swimmers shown the longer training time per week (20.07 ± 4.07 hour; 20.13 ± 4.17 hour, respectively). Discussion The volume of training per week is lower than the recommendation for elite athletes (25-30 hours per week) (Baker et al. 2003). This recommendation is not met by either males or females. In regards to age, younger athletes train more hours per week than older athletes, this could indicate the relevance of the training intensity in older athletes (Tota et al., 2015) The volume of training per week is lower than the recommendation for elite athletes (25-30 hours per week) (Baker et al. 2003). This recommendation is not met in either males or females. In regards to the age, the younger athletes train more time per week than older athletes, this could indicate the relevance of the training intensity in older athletes (Tota et al., 2015). Finally, artistic gymnastic athletes and swimmers reported more training hours per week than other athletes. That could be explained by high physical, technical and psychological demands of this two sports. References Baker J., Cote, J., Abernethy, B. (2003). *J Appl Sport Psych*, 15(1), 12–25. Laursen, P. B. (2010). *Scand J Med Sci Sports*, 20, 1–10. Tota, L., Maciejczyk, M., Pokora, I., Cembla, J., Pilch, W., Patka, T. (2015). *J Hum Kinet*, 49, 149–158.

WEIGTLIFTER TRAINING PROCESS DESIGN TAILORED TO INDIVIDUAL GENETIC TRAITS

AXENOV, M.O.

Buryat State University

Introduction It is known that efforts to mobilize individual strength qualities in a weightlifter may be limited by specific genetic traits of the athlete's body. Training process design with an emphasis on the workloads and intensities tailored to the specific genetic traits of weightlifters may provide a basis for the training process being managed in a most efficient manner. This idea was the prime reason for the study to analyze genetic traits of elite weightlifters and compare them with their adaptation progress under variable training workloads. Methods We applied a DNA genetic analysis based on polymerase chain reaction (PCR) data flow generated in a real-time mode to identify and rate the genetic-trait-specific performance efficiency of elite weightlifters in the training process. Furthermore, we developed and applied a special Sport 3.0 Computer Software for analysis of the training workloads under the study. This software was designed to provide data on the workload values, variations and correlations in the course of the subject athletes' training cycles. Subject to the tests and analysis were 110 professional athletes who were tested for ACE, ACTN3, PGC1 α and MSTN genes. The test data were processed using regular mathematical statistic tools. Study results The athletes tested with SS genotype of PGC1 α gene were found to demand the lowest workloads [to attain the same result] in the macro-cycle training process versus that of the athletes tested with other genotypes of the same gene. The athletes having a heterozygote or tested with LL genotype of MSTN gene also showed better performance in adaptation to the training workloads over the training process macro-cycle ($P < 0.01$) Discussion The elite athletes tested with SS genotype of PGC1 α gene were found to comprise 21.6% of the total sample. This genetic trait appears to give them advantage in the macro-cycle training process as they require 1.5 lower training workloads in the process [to achieve the same result] versus the athletes tested with some other genotypes (Aksenov M.O., 2015). We copied the athletes' individual training workload data records from their training logs and input these data into the application Sport 3.0 Computer Software to rate the workloads versus the tested genotypes. The study data and analysis confirmed the athletes tested with LL genotype and heterozygote in MSTN gene also having an adaptation advantage in the process (Akhmetov I.I., 2015). COMPARISON OF INTRA-ABDOMINAL PRESSURE IN MAXIMAL ARM STROKE, LEG KICK AND WHOLE BODY SWIMMING

MORIYAMA, S.1, KANAZAWA, S.1, KITAGAWA, Y.1, NAGANO, Y.1, SHIBATA, Y.2, OGITA, F.3

1:Japan Women's College of Physical Education, 2:Tokyo Gakugei University, 3:National Institute of Fitness and Sports

Introduction Arm stroke (A) and leg kick (K) training as well as whole body swimming (S) have been used in the daily training regime. Since intra-abdominal pressure (IAP) as an index of trunk stability in S increases with swimming speed (Moriyama et al., 2014b), it is suggested that to enhance IAP is important for improving swimming performance. However, IAP in S with front crawl swimming has been already determined (Moriyama et al. 2014a,b), but not those in A and K. Therefore, this study aimed to determine how extent IAP increases in maximal A and K, and to compare them to that in maximal S. Methods Eleven well trained competitive collegiate female swimmers (height 1.61 ± 0.04 m, weight 54.9 ± 5.8 kg, maximal IAP in the Valsalva maneuver 11.7 ± 4.8 kPa) participated in this study. Subjects performed A, K and S with maximal effort in a normal swimming pool. IAP was taken as the difference between minimum and maximum values using the mean of 3 stable front crawl stroke cycles. IAP in A, K and S were normalized based on the maximal voluntary IAP obtained with the Valsalva maneuver (%maxIAP). Results IAP and %maxIAP in S (2.7 ± 0.5 kPa, $25.7 \pm 8.7\%$) were significantly higher than those in both A (1.1 ± 0.5 kPa, $9.5 \pm 2.4\%$) and K (1.8 ± 0.5 kPa, $17.3 \pm 8.1\%$), and furthermore those in K were significantly higher than in A. IAP in A and K corresponded to 39.9 % and 66.8 % of that in S, respectively. On the other hand, when IAP in S was compared to the sum of IAP in A and K (2.9 ± 0.8 kPa), no significant difference was found between them. Discussion In this experiment, IAP in A and K were significantly lower than that in S, and that in K was significantly higher than that in A. However, no significant difference was observed in IAP between S and the sum of A and K. It has been suggested that an increase in IAP is responsible for the action of the upper and/or lower limbs (Harman et al. 1988), intensity and velocity of movement (Cresswell et al. 1994). Our findings agree with suggestion in previous studies, and imply that IAP in front crawl swimming depends on amount of muscle activity on each limbs involved in A and K. EFFECT OF THE TRAINING PROGRAM APPLIED TO ELITE WRESTLERS ON SOME PHYSICAL, PHYSIOLOGICAL AND BIO-CHEMICAL PARAMETERS

ÇANKAYA, C.

Uludag University

INTRODUCTION Until today wrestling training programs have been prepared either single-ended or double-ended. For since wrestling championships organized in the senior, junior and schoolboy categories are held in the form of one or two tournaments a year, these two programs have kept their validity. However, today, it has become a necessity to prepare multi-ended programs especially for elite wrestlers. The most important reason for this is the increase in the number of tournaments in a year in which elite wrestlers are required to show the highest performance. Therefore, the purpose of the study was to determine if the three-month training program applied to the elite wrestlers had any effects on some physical, physiological and biochemical parameters. **METHODS** 21 male freestyle wrestlers (mean \pm SD; age 19.5 ± 2.7 year, height 172.6 ± 7.6 cm, weight 80.6 ± 16.5 kg), who have been performing wrestling for approximately 9 years, volunteered in the present study. The subjects were applied in the three-month training program which was planned according to double-ended training periodisation. At the beginning and end of the program, the subjects were administered the body composition measurement, vertical jump test, handgrip strength test and biochemical analysis (Rbc, Hct, Hb and blood glucose). **RESULTS** At the beginning and end of the training program was determined respectively that the subjects' average vertical jumps were 39.8 ± 4.3 cm and 42.1 ± 3.9 cm, right paw strengths 49.8 ± 7.9 and 53.5 ± 8.1 kg ($p < 0.05$), left paw strengths 46.3 ± 7.5 and 51.1 ± 7.4 kg, RBC 4.41 ± 0.01 ($\times 1012/l$) and 4.57 ± 0.02 ($\times 1012/l$), HCT between 0.369 ± 0.001 and 0.401 ± 0.002 (l/l), Hb 132.1 ± 0.35 and 135.5 ± 0.52 g/l, blood glucose resting 97 ± 5.1 and 88 ± 4.45 mg/cm³ ($p < 0.05$). **DISCUSSION** Mirzai et al. found that the two different training programs which they applied to the wrestlers increased strength, hypertrophy, anaerobic force and endurance in them. Some studies indicate that strength increase affects other characteristics of performance (endurance, speed and the like) in a positive way^{2,3}. It is observed that the positive effects which the training program applied in our study had on the wrestlers' anaerobic force and static strengths are similar to those of the above-mentioned studies. In conclusion, qualitatively and quantitatively detailed, different training programs applied to wrestlers have positive effects on wrestlers' biochemical, physical and physiological characteristics. For this reason, it is suggested that training programs be prepared by sport scientists and trainers via considering these effects of training programs. **REFERENCES** 1.Mirzaei B, Arazi H, Curby D, Barbas I, Moghaddam Mg, Hosseini Y. ASSESSMENT OF AEROBIC AND ANAEROBIC CAPACITY OF SWIMMERS. A PILOT STUDY

LAMPADARI, V.1, ROZI, G.1, THANOPoulos, V.1, PYRPyLIS, P.1, DOPSAJ, M.2, OKCIC, T.3

1:UOAPHED (Athens, Greece), 2: FSPE (Belgrade, Serbia), 3: FSPE (Nis, Serbia)

Introduction Significant modulations of the body's ability to produce energy through the aerobic and anaerobic metabolism occur during adolescence. The measurement of lactic acid in different swimming events is of particular scientific interest and is also a useful tool for coaches in order to assess anaerobic capacity of the swimmers (Avlonitou, 1996). The purpose of the present study is to identify differences between swimmers of various distances: a) short, b) medium and c) long, during a 100m effort of maximum intensity and a 400m effort in each swimmer's individual lactate threshold intensity (Olbrecht, 2000). **Methods** The sample consisted of n=16 swimmers (12 male, aged 16.1 ± 1.5 years, and 10 female, aged 15.4 ± 0.7 years). The sample was divided in swimmers of short, medium and long distances. All swimmers swam in different sessions a) 100m freestyle swimming of maximum intensity and b) 400m freestyle swimming in each swimmer's individual lactate threshold intensity. Immediately after each effort capillary blood samples were taken at the 3rd, 5th and 7th minute of passive recovery and were analyzed by the automatic analyzer Scout Lactate Germany. Heart rate was measured with a Polar Finlande device and performance time with a handheld stopwatch Seiko Water Resistant 10bar S140. Results Anova analysis showed no statistically significant differences between the three groups of swimmers (short, medium and long distances) for the measured variables of the 100m and 400m freestyle. A statistically significant difference was observed only in heart rate of short distance swimmers for the 100m effort compared to the two other groups (187.0, 177.6, and 162.0 beats/min, for short, middle and long distance swimmers respectively, $Sig. .005$). Lack of significant results may be due to small number of sample or maybe the sample did not try much. **Discussion** Such measurements are useful for swimming coaches in order to access performance characteristics of the swimmer during a racing year. Future researches should focus on larger sample in order to achieve more accurate results. **References** Avlonitou E. (1996). J Sport Med Phys Fit, 36, 24-30. Olbrecht J. (2000). RECOVERY STRATEGIES IN GERMAN ELITE JUNIOR TENNIS PLAYERS

SIBAI, R., SCHNEIDER, C., FETT, J., WIEWELHOVE, T., ULRICH, A., FERRAUTI, A.

Ruhr-University Bochum

Introduction Tennis is characterised with high psychophysiological demands through a year-round high number of matches. Elite junior tennis players participate in up to 25 tournaments (i.e. 50-120 single matches) and devote a great amount of training (i.e. 20h/week)[1]. Therefore, the use of recovery strategies (RS) on a daily basis might be beneficial to reduce fatigue and accelerate recovery, even in young ages. Therefore, the aim of the study was to investigate the RS implemented in German elite junior tennis players. **Methods** During the biannual German Physical Condition Tennis Testing [2] 235 elite junior tennis players participated in a questionnaire obtaining quantity and frequency of the following RS: active recovery (AR), to shower (SH), ice bath (ICE), foam rolling (FR), 'regeneration drink' (RD), rest and nap (NAP), compression apparel (CA), food (FO), massage (MAS), listening to music (MU), sauna (SAU), stretching (STR). Frequency was investigated using 3 levels: regularly, occasionally, never. 192 (118 male, 74 female; age 10-18) of the initial 235 questionnaires were completed without missing values. Differences between sex and age-groups (U12,U14,U16,U18) were analysed using Chi²-Tests for nominal data (quantity of RS), Kruskal-Wallis and U-Test for ordinal data (frequency of RS). Effect size (ES) was interpreted as small 0.1, moderate 0.3., large 0.5. Results Descriptive analysis showed that 'common' RS (SH 97%, FO 95%, AR 94%, STR 91%, MU 90%, NAP 89%) were used more often than 'sophisticated' RS (MAS 60%, FR 60%, RD 57%, SAU 30%, CA 23%, ICE 18%). A similar ranking was observed for both sexes. Overall 'traditional' RS were used more regularly, whereas 'modern' RS were used more occasionally. Male athletes showed higher quantity (ES=0.22, $p < .01$) and frequency (ES=0.20, $p < .01$) in RD, as well as a higher quantity in NAP (ES=0.24, $p < .01$). Age-group differences were found both in quantity and frequency in FR (moderate, ES=0.43-0.48, $p < .001$), STR and SAU (small, ES=0.24-0.29, $p < .05$). Older athletes used FR more often and regularly (ES=0.16-0.50, $p < .05$) with no difference between U16 and U18. U18 used SAU most often and regularly (ES=0.18-0.38, $p < .05$), while in STR U12 showed smaller values in quantity and frequency to U14 and U16 (ES=0.17-

0.28, $p<.05$). Discussion Results indicate that RS are highly implemented in German elite junior tennis players with a tendency to 'common' RS being favoured. Observed differences were predominantly of small size. Only FR data indicated subsequent increase in use with age. In conclusion we suggest that further investigations should focus on the effectiveness of the players individual recovery routines. LOADED VERTICAL JUMP AS INDICATOR OF SWIMMING START PERFORMANCE

GARCIA-RAMOS, A.1, ŠTIRN, I.2, PADIAL, P.1, ARGÜELLES-CIENFUEGOS, J.3, DE LA FUENTE, B.3, CALDERÓN, C.3, BONITCH-GÓNGORA, J.1, TOMAZIN, K.2, STRUMBELJ, B.2, STROJNIK, V.2, FERICHE, B.1

1: Faculty of Physical Activity and Sports Sciences, University of Granada (Granada, Spain); 2: Faculty of Sport, University of Ljubljana (Ljubljana, Slovenia); 3: CAR Sierra Nevada (Granada, Spain).

Introduction Swimming start performance, commonly defined as the time to 15m, is a good predictor of overall race time in the four swimming strokes (Mason & Cossor, 2000). The horizontal take-off velocity of the push-off is the variable that most influences swimming start time (Tor et al., 2015). Previous studies have also proved the importance of possessing high levels of lower body strength and power to optimise swimming start performance (West et al., 2011). In this regard, we aimed to examine the correlation of different dry land strength and power tests with swimming start performance in experienced female swimmers. Methods Twenty-one international level female swimmers performed different dry land strength (leg extension maximal voluntary isometric contractions) and power tests (squat jumps with additional loads of 0%, 25%, 50%, 75% and 100% of swimmers' body weight (BW)) as well as a maximum freestyle swimming start on a single testing day. Correlations between the time to 15m, several variables collected with a force plate during the start push-off phase, and the dry land tests were quantified through Pearson's linear correlation coefficients (r). Results The time to 15m was inversely correlated to the peak velocity reached during the loaded squat jump with 25–100% of BW ($r = -0.63$ to -0.68), while no significant correlations were observed neither for the unloaded squat jump ($r = -0.23$) or the isometric test ($r = -11$ to -0.15). The horizontal take-off velocity ($r = -0.56$), average horizontal force ($r = -0.62$), and average horizontal acceleration ($r = -0.58$) were the push-off variables most related to 15m time. However, only the horizontal take-off velocity was significantly correlated with the squat jump peak velocity ($r = -0.45$ to -0.64). Discussion Our results are consistent with previous studies indicating the need of possessing high levels of lower-limb muscular power to optimise swimming start performance (West et al., 2011). The assessment of the peak velocity during vertical jumps with external loads relative to BW seems to be a good indicator of both horizontal take-off velocity and swimming start time. MONITORING PHYSICAL ABILITIES AND SEASONAL FLUCTUATIONS IN ELITE YOUTH SOCCER PLAYERS

CONNOLLY, D., FERRARI-BRAVO, D., GUALTIERI, A., SASSI, R.

Juventus FC

Introduction The quantification of fitness levels and players physical characteristics is increasingly important in youth soccer. Monitoring seasonal variations across different age groups is key for the long-term development of players' physical abilities and talent identification (Deprez, 2015). The aim of this study was to determine the physical characteristics of elite-level youth soccer players across different age groups, evaluating between role differences and in-season variations of physical abilities. Methods 252 youth soccer players' were assessed across four competitive seasons. The players, ranging from U14 to U17 age groups, performed the Yo-Yo intermittent recovery test level 1 (YYIR1), a counter-movement jump test with arm swing (CMJA) and a 20m sprint test three times during the competitive season (Pre-season, T1; Mid-season, T2; End-season, T3). Players who performed all 3 test sessions (612 observations) were considered for analysis. Differences between age groups, season period and playing position were analyzed using repeated-measure ANOVAs for each dependent variable and Bonferroni post-hoc analysis. Results Significant differences were found between age groups for YYIR1 (2470 ± 374 vs 2280 ± 469 , 1960 ± 500 , 1370 ± 473 m for U17 vs U16, U15 and U14 respectively, $p < 0.003$) and sprint performance (U17, 2.85 ± 0.09 ; U16, 2.89 ± 0.11 ; U15, 2.95 ± 0.11 and U14, 3.02 ± 0.14 s; $p < 0.018$). U14 and U15 were not significantly different for CMJA ($p = 0.228$), but both were significantly lower than U16 and U17 ($p < 0.036$). CMJA performance was significantly greater in U17 than all other age groups (U17, 45.3 ± 4.8 ; U16, 43.2 ± 4.9 ; U15, 41.8 ± 4.2 ; U14, 41.0 ± 4.8 cm). Within-season changes were significant for YYIR1 and CMJA ($T3 > T2 > T1$, $p < 0.001$ and $p < 0.039$ respectively). Sprint times improved significantly between T1 and T2 (-1.2%, $p = 0.003$) with only a trend between T2 and T3 (-0.8%, $p = 0.069$). Each of the physical tests noted significant differences for player position: midfielders CMJA and sprint ability were significantly lower ($p < 0.003$) than attackers (AT), central defenders (DC) and wingers. AT performed significantly better than DC across all 3 physical tests ($p < 0.017$). Discussion These findings highlight the significant physical differences that exist between different age groups in youth soccer. In-season training and physical development can significantly impact upon these performance variables. Monitoring the development in elite-level youth soccer can facilitate both players' selection and individualization of the training process in accordance with players' physical characteristics. PHYSIOLOGICAL PROFILE OF MALE AUSTRIAN NATIONAL TEAM LACROSSE PLAYERS

HAUER, R., TSCHAN, H.

University of Vienna

INTRODUCTION The knowledge of the physiological requirements of lacrosse athletes is quite limited. Lacrosse is characterized by skill, speed, agility, strength, flexibility, and a mixture of aerobic and anaerobic activity (Collins et al., 2014). This study aims to describe the fitness profile of male Austrian national team lacrosse athletes. Further, it compares the evaluated profile with existing research of US

intercollegiate lacrosse athletes. METHODS A lacrosse specific fitness test battery was created to represent basic health-related fitness parameter. Including cardiovascular endurance (1-mile run), maximal strength (1 repetition maximum for bench press BP and back squat BS), speed (40-yard sprint), agility (t-run test), lower body power (vertical jump) and anthropometric analysis (height, weight and skinfold measurement). All tests were performed based on scientific guidelines (e.g. Baechle & Earle, 2008). Further, a lacrosse specific test (wall ball test) was developed to assess passing and catching skills. A total of 18 male Austrian national team lacrosse players were tested. The differences between collected mean values and existing NCAA college lacrosse athletes (e.g. Gutowski & Rosene, 2011) were evaluated by a 1-sample t-test. Statistical significance was set at $p<0.05$. RESULTS Anthropometric analysis showed no significant differences in height (1.81 ± 0.66 m) and body mass (83.17 ± 9.20 kg), but lower body fat values ($11.41\pm3.85\%$) in the observed group. The physiological mean values were significant lower for vertical jump (50 ± 6.41 cm, $p=0.00$), BP (74.9 ± 14.10 kg, $p=0.00$) and BS (103.2 ± 16.48 kg, $p=0.00$). Higher t-run (10.6 ± 0.62 s, $p=0.00$), 1-mile run (394.56 ± 42.66 s, $p=0.00$) and lower 40-*yd* sprint (5.13 ± 0.18 s, $p=0.00$) times were determined. No normative values exist for the wall ball test (18.88 ± 7.25 rep). DISCUSSION It can be concluded that male US college lacrosse players have a higher overall fitness than their Austrian counterparts. According to uniform test guidelines future studies should focus to create a physiological profile of European male and female lacrosse players. Compared with values for US collegiate lacrosse athletes these results would show possible weaknesses among international lacrosse players. This could lead to implement proper athletic strength and conditioning programs for European lacrosse athletes to increase performance and reduce injuries. REFERENCES Baechle, T.R. & Earle R.E. eds. RELIABILITY OF A NOVEL POSTERIOR LIMB ISOMETRIC MUSCLE TEST IN FOOTBALL PLAYERS

ALCARAZ, P.E.1, ABEDIN-MAGHANAKI, A.1, MATINLAURI, A.1, FREITAS, T.1, TOSCANO, F.J.1, MARTÍNEZ-RUIZ, E.1, MEN-DIGUCHIA, J.2, COHEN, D.D.3

1. Research Center for High Performance Sport (CIARD-UCAM). Murcia, Spain. 2. Zentrum Sport. Pamplona, Navarra, Spain. 3. University of Santander. Bucaramanga, Santander, Colombia.

Introduction Fatigue and strength deficits are important predisposing factors for hamstring strains (1). McCall et al (2) demonstrated the reliability of a posterior lower limb test performed on a portable force platform as a practical tool to monitor posterior limb isometric peak force (PL-IPF) in team sport athletes. They also showed that this test performed in two supine positions, was sensitive to match induced fatigue in footballers. However, evidence suggests that hamstring fatigue following simulated football is greatest close to full knee extension (3) and the majority of hamstring strains are thought to occur to the biceps femoris in an extended position (1). Therefore, we aimed to determine the reliability of a test which assesses PL-IPF in such a position. Methods Fourteen semi-professional male football players were tested twice, on consecutive weeks. PL-IPF was measured with two tests, both performed in a standing position with the tested leg positioned on a portable force platform at 90° hip flexion and 20° knee flexion (90:20). The non-tested leg, upper back and head were positioned against a wall and the arms were either (i) crossed on chest, palms placed over the contralateral acromion (AC); or (ii) next to trunk against the wall, elbows fully extended and palms in pronated position (AW). Results There was no effect of test protocol or leg on PL-IPF. Differences between repeated trials displayed trivial or small effect sizes in both positions and in both dominant (DOM) and non-dominant (NON) legs; AW-DOM; CV=12.4%, ICC=0.63, $p=.044$. AW-NON; CV=12.2%, ICC=0.82, $p=.002$. AC-DOM; CV=14.5%, ICC=0.71; $p=.018$. AC-NON; CV=9.2%, ICC=0.90; $p=.001$. Discussion Both versions of the 90:20 showed good-to-high reliability with the AC position slightly superior. In all conditions, except for the AW-DOM, CV's were close to 10% and ICC's to 0.75, qualifying values often used to define a variable as reliable (4). The 90:20 can be considered a reliable means to rapidly assess PL-IPF with the biceps femoris in an extended position. Further research should evaluate the capacity of the 90:20 to detect post-competition fatigue and to compare muscle activation in the 90:20 versus supine tests (2). References 1. HIGH TEST-RETEST RELIABILITY OF TEST-DURATION AND VO2MAX WITH A SOFTWARE SUPPORTED RAMP-TEST FOR ROWING ERGOMETRY

WINKERT, K., PIEPER, L., STEINACKER, J.M., TREFF, G.

University Hospital of Ulm

Introduction Wind braked ergometers like the Concept 2 rowing ergometer do not allow external control of power, because the athlete himself has to create the demanded resistance by acceleration of the fly wheel to a corresponding angular velocity. To improve discipline specific maximal oxygen uptake (VO2max) measurements, we developed a software supported ramp test protocol for wind braked rowing ergometers. The test allows a continuous and linear increase of power and contains an automatic termination criterion. The purpose of this study was to quantify the test-retest-reliability of test duration and VO2max when the test is terminated automatically. Methods Five female (height 173.1 ± 1.9 cm, mass 64.7 ± 7.7 kg, VO2max 3.4 ± 0.17 l•min $^{-1}$) and 5 male (184.0 ± 6.3 cm, 73.9 ± 6.6 kg, 4.2 ± 0.50 l•min $^{-1}$) competitive rowers underwent a familiarization session and two consecutive ramp tests separated by one day up to automatic test termination on a Concept 2 rowing ergometer. Tests started with 160 W in male and 120 W in female rowers and increased by 30, 25, or 20 W•min $^{-1}$, depending on individual fitness to allow for a test duration of 8 to 12 min. The ergometer was modified with a load cell for force measurement and a rotary transducer (FES, Berlin). An external computer visualized exact power output in real time. A warning occurred when the average of two strokes was more than 7 W below target power. The test was terminated with the fifth warning. To prevent premature dropout, warnings were deleted after four consecutive strokes within ± 7 W of target power. VO2max was measured with a metabolic analyzer (Ergostick, Geratherm respiratory). Test-retest reliability of test duration and VO2max were determined by typical error of measurement (TE), intraclass correlation coefficient (ICC), and minimal detectable change (MDC). Results Test-retest reliability of test duration amounted to TE = 2.8% (95 CI 1.9 – 5.2), ICC = 0.96 and MDC = 7.8%. VO2max was TE = 4.8% (95 CI 3.3 – 8.9), ICC = 0.93 and MDC = 13.3%. Discussion The results showed a high reliability of test duration. The MDC of 4.8% indicates that a noticeable change in test duration corresponds to an increase of 37 s in a rower who was able to perform for 8 min before dropout e.g. a baseline test, equaling to approx. 19 W max power. Reliability of VO2max was lower, but within the expected range. This results underlines that differences in VO2max have to be relatively high to ensure relevant changes in ability. We conclude that the automatic test termination is feasible and allows an objective and reliable cessation of the ramp test. Kay.Winkert@uniklinik-ulm.de

EVALUATION OF THE EFFECTS OF CORE TRAINING ON THE CORE STRENGTH, STATIC AND DYNAMIC BALANCE CHARACTERISTICS OF TENNIS ATHLETES IN THE 8-14 AGE GROUP

GUR, F., ERSOZ, G.

Karadeniz Technical University, Ankara University

The purpose of this study is to investigate the effects of core training performed regularly for 12 weeks on the core strength and the static and dynamic balance characteristics of male tennis athletes in the 8-14 age group. Nineteen male tennis athletes (the mean age was 10.68 ± 2.18 , mean length was 146.85 ± 15.06 cm, and mean body weight was 43.34 ± 16.97 kg) attending in the Pamukkale Tennis Club were included in the study on a voluntary basis. Athletes participating in the study were divided into experimental group ($n=10$) and the control group ($n=9$) by randomized method once classified according to their age group. In the study, an experimental method with a pre-test and post-test design pattern was used, and the experimental group performed core training 3 days a week for 12 weeks in addition to tennis training, whereas the control group continued to the regular tennis training, without any intervention. Core strength, static and dynamic balance test measurements of the experimental and control groups were carried out twice, before and after 12-week training program. Data were analyzed using SPSS (Ver.20) package program. The values obtained by the pre-test and post-test were compared statistically by means of Paired sample t-test and Wilcoxon Two-Related-Samples test, after looking at the normality distribution with the Shapiro-Wilk test. A probability level of $p < 0.05$ was used to indicate statistical significance for all statistical methods. As a result of the 12 weeks of core training program, the mean core strength of the experimental group was 146.70 ± 28.77 s after the training, whereas it was 120.50 ± 26.30 s before the training ($p < 0.05$). And, the mean core strength in the control group was 85.44 ± 25.49 after the training, whereas it was 80.11 ± 36.12 s before the training ($p > 0.05$). According to these results, the applied core training was found to increase the core strength significantly. However, no significant difference was found between the experimental and control groups in terms of mean static and dynamic balance values before and after training ($p > 0.05$). As a result, the core training was found to have a positive effect, in terms of sporting performance, on the core strength and balance of tennis athletes. However, further studies should be conducted with core training models designed differently to better understand the relationship between the core training and balance performance.

TAPERING STRATEGIES FOR 20-KILOMETER RUNNING: PRACTICAL CASE OF JAPANESE UNIVERSITY MALE DISTANCE RUNNERS

SHIMAZU, W., TANJI, F., TAKAYAMA, F., NABEKURA, Y.

University of Tsukuba

Introduction Taper is defined as a reduction in training load during the final days before a competition, with the aim of optimizing performance. The most efficient strategies are exponential training volume reduction from the overload training period [OT] to the taper training period [TT] without altering training intensity or frequency (Bosquet et al., 2007). Tapering strategies based on this theory are applied to many sports, but it has not been established that training intensity changes for the specific situation. Therefore, the purpose of this study was to clarify the relationships between the changes in training load from OT to TT and the 20-km race performance in Japanese university male distance runners. Methods Eleven male university long-distance runners (maximal oxygen uptake: $\text{VO}_2\text{max } 71.7 \pm 4.2 \text{ ml kg}^{-1} \text{ min}^{-1}$) participated in this study. They completed a 4-week OT and 1-week TT before a 20-km race. Running distances and training sessions per week were regard as training volume and training frequency, respectively. Training intensities were divided into four zones: [zone1] \leq Lactate threshold $<$ [zone2] \leq Onset of blood lactate accumulation $<$ [zone3] \leq $\text{VO}_2\text{max} <$ [zone4] based on the results of maximal and submaximal incremental tests. The tapering achievement ratio was evaluated by comparing the 20-km race time and predicted 20-km time calculated by using the seasonal 5000-m best time (Riegel, 1981). The percentages of training volume at each intensity of overall training in OT and TT, and the ratio of TT/OT for those percentages were calculated. Results The 20-km race time was significantly lower than the predicted 20-km time (63.9 ± 1.5 and 65.1 ± 2.0 min, respectively, $p < 0.05$), the tapering achievement ratio was $101.9 \pm 1.8\%$. The percentages of training volume were 69.6 ± 2.2 , 15.4 ± 1.4 , 13.3 ± 1.2 and $1.7 \pm 0.2\%$ during OT and 85.6 ± 4.2 , 2.8 ± 3.9 , 11.1 ± 1.9 and $0.5 \pm 0.5\%$ during TT at [zone1], [zone2], [zone3] and [zone4], respectively. The percentages of training volume at intensity [zone2] + [zone3], corresponding with running velocity during the 20-km race, of overall training in OT and TT were 28.7 ± 2.1 and $13.9 \pm 4.3\%$, respectively. We observed a significant positive relationship in the tapering achievement ratio and the ratio of TT/OT ($p < 0.05$, $r = 0.75$). Discussion The tapering achievement ratio was related to the ratio of TT/OT. These results suggest that training at an intensity near target race pace should be maintained during the taper training period even if 20-km race is the aim. MO-PM48 Rehabilitation: Physiotherapy

QUANTIFYING RETURN TO FITNESS AFTER KNEE INJURY USING GAIT ACCELEROMETRY

SUMMERS, H.D., JENNER, O.R., BARNES, C.M., HOLTON, M.D., REES, P.

Swansea University

INTRODUCTION The assessment of rehabilitation status for musculoskeletal injuries, in both sports and clinical arenas is still predominantly by measures based on observation and palpation [1]. Whilst errors stemming from the subjectivity of these approaches can be reduced through diligent use of standardised criteria [2] they cannot be completely removed and marked variability between assessors is common [3]. To address this we present an objective approach that uses quantitative, accelerometry-based metrics to create a scoring system for recovery from knee injury. METHODS The test subject was a 19 year-old male who had recently undergone knee surgery to repair a severely torn right meniscus. At 11, 19 and 48 weeks post-surgery gait analysis of treadmill running was performed, using ankle mounted accelerometers on both legs. The radial acceleration component was collected at 40 Hz and comparative assessment of left and right leg motion obtained from frequency and correlation analyses. RESULTS The acceleration frequency spectra from the injured leg

displayed increased power in the higher harmonic components due to the altered gait. The prominence of these frequency components decreased as the subject recovered from injury. Cross correlation of the left and right ankle acceleration traces of a 90 second running sequence provided a quantitative recovery score based on the similarity of left and right limb gait. The recovery score when running at a speed of 15 km hr⁻¹ progressed from 16% at week 11 to 31% at week 19 and 57% at week 48. The score at week 48 when walking at a speed of 4 km hr⁻¹ was 91%. CONCLUSIONS The alterations to leg motion in walking and running caused by knee injury can be measured using ankle mounted accelerometers. Cross-correlation of accelerometer traces from injured and non-injured legs provides an integrative measure of the similarity of movement between limbs, conveniently scaled between 0 to 100% that can be used for quantitative assessment of return from injury. Introduction In athletes arises after an injury of the anterior cruciate ligament, the question of when he can return to his sport again. The return time is very individual and depends on many factors. There are a variety of tests to determine the earliest possible time of return by individual tests or combined tests. An on-going study examines the sport ability after anterior cruciate ligament reconstruction preoperative and 6 month after anterior cruciate ligament. The project examines the postoperative recovery of sports ability. The aim of this work is to preoperatively identify the existing deficit to the not injured side and compare the results after 6 month rehabilitation phase. Method 7 athletes, moderate activity level (age: 23.4 ± 2.8 years, m = 5, w = 2) with isolated anterior cruciate ligament injury were examined preoperatively. In addition to the collected questionnaires of thigh circumference, the isometric force of knee extensors and flexors, and the one-legged landing characteristics (20 cm jump height) was captured on a force plate and a three-dimensional motion analysis system. Three isometric strength values for the knee extensors and flexors per side were measured and averaged. Results Preoperatively we found a reduced thigh circumference of 4.3 ±14.2 mm on the injured leg. After 6 month the value increased to 14.5 ±16.6 mm. Percentage of force (extensors to flexors) of the injured side before surgery was 58.2 ±19.8% and after 41.5 ±7.4%. Sound side: 49.3 ±10.3% to 50.4 ±12.5%. Sagittal knee angle at landing was 17.8° ±5.4 at the beginning and after 19.7 ±2.9°. Sound side: 15.2 ±5.0° to 18 ±2.6°. Max. knee angle in the landing phase was 34.0 ±14.0° and 47.0 ±10.9°. Sound side: 37.3 ±13.5 to 48.4 ±11.8°. Sagittal knee moment changed from 1062 ±1030 to 2078 ±1000 Nm and frontal knee angle moment from 318.4 ±374.4 to 606.7 ±445.8 Nm. sound side: 1668.6 ±971.46 to 2536 ±1004 Nm and 252 ±307 to 590 ±416 Nm. Discussion Preoperatively reduced moments were present at the injured side, combined with a higher landing angle at the knee. After 6 month there exists a higher landing ROM in the injured leg and similar to the sound side. The relationship of extensor to flexor force has further decreased on the injured leg. From these results we can conclude that the force development and the force relationship on the injured side are still reduced. On the other hand we found an adjustment of the landing strategy to the non-injured leg. Overall, no symmetry of values between the injured and non-injured leg has been established and further training is absolutely necessary to be fully operational again.

NEW METHODOLOGICAL APPROACH TO RTD EVALUATION IN RELATION TO HAMSTRING STRAIN INJURIES IN FEMALE ATHLETES. A PRELIMINARY STUDY.

SETUAIN, I.1,2, BIKANDI, E.3, ETXALEKU, S.1,4, ALFARO-ADRIÁN, J.1, IZQUIERDO, M.2

1: Traumatología Deportiva Navarra (Pamplona, Spain); 2: UPNA (Navarra, Spain); 3: Athletic Club de Bilbao (Bilbao, Spain); 4: CEIMD (Navarra, Spain)

Introduction Hamstring strain incidence is associated with high speed running actions. Isokinetic dynamometer is described as a useful tool for strength evaluation throughout the rehabilitation process. The rate of torque development (RTD) is valid to assess muscle central motor output during contraction (Marshall et al., 2014). The RTD examination could check the neuromuscular system status after having undergone the rehabilitation process. The objective of this study was to describe the hamstrings peak torque (PT) and RTD in athletes who sustained medial or lateral hamstring strain injury after fulfilling a criterion-based rehabilitation protocol. Methods 4 female track and field athletes [Age 17-3 years (mean SD); height 165 ± 8 cm; weight 65 ± 13 kg] who suffered a medial or lateral hamstring strain conducted an isometric strength testing evaluation using an isokinetic device (HUMAC NORM Isokinetic Extremity System, CSMi, Stoughton, MA) at the end of the rehabilitation period. The PT (N.m) and RTD (N.m/s) during the first 200 ms were recorded for both healthy and injured limbs at 15° (for lateral hamstring) and 90° (for medial hamstring) knee flexion angular position. RTD calculations were automatically processed with the implementation of a self customized program (Matlab v. 7.5.0.342 [R2007b] USA). Results Hamstrings PT did not differ between the injured and healthy limbs, (mean SD 149.67 ± 41.17N vs. 149.75 ± 15.63N respectively [P=0.18]). Time for PT was 2327.5 ± 1202.6 ms vs. 2260 ± 872.9 ms for injured and healthy limb, respectively (P=0.136). Finally, there was a significant reduction in maximal RTD in the injured limb in comparison to the healthy limb (778.87 ± 196 vs. 903.5 ± 253.69 N.m/s respectively [P=0.006]). Discussion The observed RTD reduction in the hamstring strained limbs after completing the rehabilitation process could constitute a lasting neuromechanical deficit in hamstring muscles post injury, related to previously described risk factors for hamstring injury, such as neuromuscular inhibition (Fyfe et al., 2013). Despite the successful strength recovery and return to sport, neuromuscular impairment persists in terms of lower RTD ability in the hamstring injured limb. These results may be associated with the high hamstring injury recurrence rates (Marshall et al., 2014). References Marshall PWM, Lovell R, Jeppesen GK, Andersen K, Siegler JC. (2014). EIGHT WEEKS OF HOME-BASED BALANCE TRAINING NOT AS EFFECTIVE AS THERAPIST-SUPERVISED TRAINING DURING DUAL TASKS

ATTERBURY, E.

Stellenbosch University

Objectives: To assess the effect of balance training on dual-tasking gait, and to investigate if a home-based programme is comparable to a therapist-supervised programme. Background: Parkinson's disease often manifests as a loss of automaticity, and as a result gait dysfunction occurs. Difficulties with gait are aggravated when paired with a secondary cognitive task, leading to possible unsafe ambulation. Dual-tasking is an essential part of independent-living and thus important to understand what effect it has on gait, and if possible

improvements in dynamic balance can influence it. Therefore this study sets out to explore the effect of balance training, at home or with a therapist, on dual-tasking gait. Methods: This experimental study included 39 participants with mild to moderate Parkinson's disease (H&Y I–III), divided into a Therapist-supervised group (n=23, age 65.4±8.3yrs) and a Home-based group (n=16, age 64.9±7.1yrs), based on a sample of convenience. Both groups followed 8 weeks of balance training, with the Therapist-supervised group attended classes with an exercise therapist, and the Home-based group followed a series of guided DVDs at home with their caregiver. Primary outcome measures included mobility and gait parameters, assessed with the modified instrumented Timed-up-and-Go (iTUG), and dual-tasking ability, assessed with the instrumented cognitive Timed-up-and-Go (cTUG), from which dual-task interference was calculated. Secondary outcome measures included perceived fear of falling, assessed with the International Fall Efficacy Scale (FES-I), and disease severity, assessed with Unified Parkinson's Disease Rating Scale (UPDRS). Results: The Home-based group showed a significant decrease in UPDRS III scores ($p<0.001$) after the intervention, and also showed significantly increased dual-task interference for duration, stride velocity, cadence and time in double support ($p<0.005$). The Therapist-supervised group maintained their disease severity and dual-task interference after the intervention ($p>0.05$). Conclusions: The dual-task interference showed that, unlike the Therapist-supervised group, the Home-based group was unable to maintain their gait performance when a secondary task was applied. This study has revealed that eight weeks of balance training with a therapist is more likely to maintain and improve gait during dual-tasking than without the presence of a therapist performed at home.

EFFECT OF HOME-BASED VIRTUAL REALITY-AUGMENTED EXERCISE THERAPY

VILLIGER, M., LIVIERO, J., STOOP, R., AWAI, L., CURT, A., PYK, P., HOHENAUER, E., CLIJSEN, R., ENG, K., BOLLIGER, M.

University of Applied Sciences and Arts of Southern Switzerland

Introduction After injury of the brain or spinal cord, functional recovery is reduced as severed axons are restricted in their capacity to spontaneously regenerate, and compensatory fibre growth is limited. Key factors influencing successful rehabilitation and functional recovery include variety in training, intensive movement repetition, task-relevant feedback and a motivating training environment. Technologies which can provide all of these features, independent of the patient's location, may thus provide significant benefits for rehabilitation. We hypothesize that home-based and unsupervised virtual reality (VR)-augmented lower limb rehabilitation training is feasible with incomplete spinal cord injury (iSCI) patients and improves motor functions (e.g. mobility - transfer ability, strength, balance). **Methods** For our study we used a prototype of a mobile lower limb VR training system (YouKicker®) combining action observation and movement execution using motivating training scenarios. Patients using YouKicker controlled virtual representations of their legs and feet designed to facilitate the observation of goal-directed actions presumed to activate overlapping cortical networks. Clinically relevant movements were trained in different scenarios, as specified in design discussions with therapists. We have previously tested a stationary version of the system on iSCI patients and found significant improvements in lower limb function (Villiger et al. 2013). Ten subjects with iSCI completed a home-based training program with the VR device over four weeks. Before and after training, mobility (clinical outcomes) and gait quality (kinematic outcomes) were assessed. **Results** Results revealed that subjects with iSCI performed significantly better in (a) functional mobility combined with balance and lower limb muscle strength and in (b) gait quality, i.e. gait parameters, foot dorsiflexion and intralimb coordination. **Discussion** Following iSCI training with a home-based VR training device without supervision can induce positive training effects, comparable to the stationary training device, and might be useful as a rehabilitation tool. Follow-up studies should include a RCT design and other disease patterns, e.g. neurological disorders or orthopedic diseases. FELDENKRAIS METHOD IMPROVED THE FUNCTIONALITY AND BALANCE IN PEOPLE WITH INTELLECTUAL DISABILITY

TORRES-UNDA, J., GARCÍA-GIL, M., DUÑABETIA, I., RODRÍGUEZ-LARRAD, A., POLO, V., BIDAURAZAGA-LETONA, I.

University of the Basque Country (UPV/EHU)

INTRODUCTION The Feldenkrais Method (FM) is an exploratory learning approach for the improvement of body awareness and movement organization. For the first time in history, most people with intellectual disability (ID) can now expect to live as long as their non-disabled peers (1). Due to this fact, aging process and related functional problems use to occur earlier in people with ID. Different authors suggested that the FM improves the balance, reducing the risk of falls in elderly populations (2). We hypothesized that the FM could be helpful to improve the balance and functionality of men and women with ID who show signs of an early aging process. **METHODS** People with ID were recruited from a company for job integration. They were divided in Experimental Group (EG) and Control Group (CG). Participants of the EG received 30 FM class during 9 months. Participants of the CG did not receive any intervention. Height, weight, Short Performance Physical Battery (SPPB) and postural stability (Winposture platform) were analyzed before and after the programme. The protocol was fully approved by the Human Research Ethics Committee of the University of the Basque Country. **RESULTS** The average age of participants (n=32) was 48.96 ± 7.49 years old. After the programme, significant changes were not observed in anthropometry. The EG improved the performance in all of the tests of the SPPB. In the chair stand test ($p<0.005$) and in the total score of the battery ($p<0.005$) the results were significantly better at the end of the intervention for this group. The CG showed a non-significant improvement of the total score of the SPPB. The analysis of the postural stability showed significant decreases?? ($p<0.05$) in the total area (mm²) and in the speed (mm/s) for the EG. Significant changes were not found for the CG in the postural stability test. **DISCUSSION** The results of this study showed that the FM contributes to the improvement of body balance and functionality in people with ID between 40 and 60 years old. According to previous studies (3) FM could be considered as an adequate tool in ageing population, both as a preventative approach and for people at risk of falls. **ACKNOWLEDGMENTS** This work was facilitated by an agreement between the Regional Government Bizkaiko Foru Aldundia / Diputación Foral de Bizkaia, Lantegi Batuak and the University of Basque Country (UPV/EHU). **REFERENCES** 1) Fisher, K., & Kettl, P. SCHROTH EXERCISE FOR THREE CURVE BALANCED IDIOPATHIC SCOLIOSIS

LEE, S.Y., KIM, A.R., AN, K.O., LEE, H.S.

Dankook university

Introduction The Lehnert-Schroth classification has been recently widely used and simplified approach to classify into seven types of curvature (Weiss, 2010). Among the seven curve patterns, the most common pattern is the 3 curved balanced (3C) which has three blocks (Shoulder block, Thoracic-Ribcage block, Lumbo-pelvic) of the human body on coronal and transverse section, each block represents a respective twisted form (Lehnert schroth, 2007). However, previous studies have not considered these curve patterns when approaching the scoliosis patient in exercise. The purpose of this study was to investigate the effects of schroth exercise on thoracic and lumbar spine Cobb's angle and the hip joint range of motion in 3C idiopathic scoliosis patients. **Methods** Total 35 subjects (Male: 7, Female: 28, Age: 18.07 ± 5.85 years, Height: 162.73 ± 8.10 cm, Weight: 49.59 ± 9.33 kg) who have 3C idiopathic scoliosis (above 10° of Cobb's angle) participated in this study. 3C scoliosis specific schroth exercise program consisted of physio-logic, 3D made easy, fifty times and muscle cylinder, for three times a week, for 12 weeks. Thoracic and lumbar spine Cobb's angle and the hip joint internal and external rotation range of motion (ROM) were measured before and after schroth exercise. **Results** Thoracic and lumbar spine Cobb's angle were significantly decreased after exercise compared to before ($p < .001$, respectively). Hip joint internal rotation ROM (Lt. $p < .001$, Rt. $p < .05$) and external rotation ROM (Lt. $p < .001$, Rt. $p < .001$) were significantly increased after exercise compared to before. **Discussion** Schreiber et al. (2011) reported that classifying patients' curve types determine the appropriate exercise prescription for a patient. In this study, we demonstrated that schroth exercise decreases thoracic and lumbar spine in Cobb's angle and increases hip joint internal and external rotation ROM in 3C idiopathic scoliosis patients. Therefore, we suggest that the efficient treatment of idiopathic scoliosis is not only an accurate classification but also needs to individually curve a specific exercise. **References** Weiss.HR. EFFECTS OF THERAPEUTIC EXERCISE ON CLINICAL EVALUATION AND MAGNETIC RESONANCE IMAGING IN A PATIENT WITH MULTILEVEL DISC HERNIATION: A CASE REPORT

KIM, A.R., LEE, H.S.

Dankook university

Introduction Lumbar disc herniation (LDH) is a common health problem that mainly occurs in younger adults, and leads to degenerative lumbar spinal disease in older adults (Jonsson and Stromqvist, 1995). LDH most typically manifests as low back and radicular leg pain, muscle spasm and nerve functional deficits, and causes both physical and social functional impairment (Ye et al., 2015). Although several exercise programs to improve functioning and pain in patients with lumbar disc herniation have been suggested (Gencay-Can et al., 2010), it is still controversial whether therapeutic exercise plays a major role in improving multilevel LDH. This study tested the hypothesis that therapeutic exercise would be improve clinical evaluation (pain, disability, physical function) and herniated lumbar discs by using magnetic resonance imaging (MRI) in a patient with multilevel disc herniation. **Methods** A 43-year-old female presented with low back pain, radicular pain in the right lower extremity and multilevel LDH (L3-L4, L4-L5, L5-S1). The therapeutic exercise program consisted of lumbar joint mobilization, lumbar spine flexion-distraction, abdominal bridge, plank, side plank and single-leg extensions from 4-point kneeling position for 40 minutes, three times a week, for 12-week. Clinical evaluation (low back and radicular pain, lumbar disability, lumbar range of motion; ROM, lumbar isometric strength and endurance, functional movement screen; FMS) was measured pre, after 6-week (post) and 12-week (post 1), and MRI examination was carried out pre and post 1 of therapeutic exercise. **Results** Low back and radicular pain, and lumbar disability decreased at post and post 1 compared to at pre. Lumbar ROM increased at flexion, extension and lateral flexion of both sides. Lumbar isometric strength and endurance, and FMS improved at post and post 1 compared to at pre. The sizes of the herniated mass were reductions on MRI after post 1 compared to at pre. **Discussion** Dzierżanowski et al. (2013) reported that exercise can reduce pain and improve functional abilities by improving the range of movement, muscle strength and body posture in single-level LDH patients. In this study, we demonstrated that therapeutic exercise decrease low back and radicular pain, improve functional capacity and sizes of the herniated mass by increasing range of motion of the spine and muscle strength in a multilevel LDH patient. These findings have clinical implications for therapeutic exercise in a patient with multilevel disc herniation. **References** Jonsson B, Stromqvist B. (1995). Eur Spine J. 4, 202–205. EFFECT OF TOE EXERCISES ON THE MEDIAL LONGITUDINAL ARCH OF THE FOOT

SHIROSHITA, T.1, FUKUBAYASHI, T.2

1 : Gumma Paz College, 2 : Waseda University

Introduction At the European College of Sport Science (ECSS) congresses in Barcelona 2013 and Amsterdam 2014, we presented on the morphologic relationship between toe exercises and the medial longitudinal arch (MLA). In that study, we showed the relationship between the lesser toe exercise (LTE) and the MLA. However, that study used a cross-sectional method. Hence, the purpose of this study was to examine the relationship between interphalangeal joint position and MLA using the longitudinal method. **Methods** We evaluated 40 feet of 40 participants (20 men and 20 women; mean age, 20.6 ± 0.6 years; mean height, 164.9 ± 8.4 centimeters [cm]; mean weight, 57.7 ± 10.1 kilograms [kg]) who had not been hospitalized for foot or ankle injuries in the past 6 months. They were grouped ($n = 10$ per group) into the great toe flexor exercise (GTE), lesser toe flexor exercise (LTE), towel-curl exercise (TCE), and control groups. The parameters were the modified navicular drop test and arch height (AH) and range of motion of ankle dorsiflexion in knee extension position (DF). The modified navicular drop test (NDT) we developed was set at 20% of foot weight bearing while seated. Its high reliability was confirmed previously as evidenced by intraclass correlation coefficients 0.88 (1.1) and 0.86 (2.1). AH was developed by Williams (Williams 2000). In the GTE group, participants were seated and a three kg weight was placed on their distal thigh. They tilted their trunk forward and then raised their heels with their great toes, performing three sets of ten repetitions of the exercise per day. Similarly, the LTE group performed the exercise using their lesser toes. The TCE group performed complete extension and then flexion of the toes for three minutes three times per day. The control group performed their usual daily life activities. We compared the parameter values before and after the 5-week intervention. For statistical analysis, we performed the Wilcoxon signed-rank and post hoc tests (Kruskal-Wallis and Mann-Whitney tests) using IBM SPSS Statistics 20 software. A $p < 0.05$ was considered statistically significant. This study was approved by the Ethics

Committees for Human Research of Waseda University and Gumma Paz College. Results In the GTE group, none of the parameter values significantly changed. The NDT score significantly changed from 5.1 to 3.1 mm ($p = 0.007$) in the LTE group but not in the TCE group, where the DF significantly changed from 9.8° to 13.3° ($p = 0.012$). Discussion The result of TCE was similar to our earlier studies. However, it was unclear that DF changed. On the other hand, GTE did not show a morphologic relationship with MLA. In contrast, LTE increased the rigidity of MLA. Anatomically, the first tarsometatarsal joint and second to fifth tarsometatarsal joints have independent articular capsules, respectively. It was suggested that different kinematics might exist in the great toe and lesser toes.

RELIABILITY OF COUNTER-MOVEMENT JUMP PERFORMANCE, CYCLE ERGOMETER SPRINT PERFORMANCE AND CREATINE KINASE CONCENTRATION IN TEAM SPORT ATHLETES: INTEREST FOR FATIGUE MONITORING

MATHIEU, B., PEETERS, A., PISCIONE, J., LACOME, M.

French Rugby Union

Introduction With elite sport becoming more competitive over the years, the volume and frequency of training required for competitive performance has increased concurrently. Given the importance of ensuring that athletes still train and compete in a non-fatigued state to allow optimal loading (Wehbe et al. 2014), athletes fatigue monitoring is required. Thus, the aim of this study was to assess the reliability of regularly test used in elite team-sport setup. Methods Twelve sub-elite rugby union players (179 ± 3 cm; 80.2 ± 7.2 kg) carried out a complete fatigue assessment session on four occasions. To assess intra-day reliability, 2 trials were performed in the same day, interspersed with 30-min of recovery. Inter-day reliability was measured with the same protocol repeated on two separate days. Each trial consisted of a standardized warm-up, 4 counter-movement jumps (CMJ) measured with a linear-encoder (Gymware, Kinetic Performance Technologies, Australia), a blood Creatine Kinase (CK) measurement (Reflotron, Roche, France) and two maximal 6-second sprint cycle efforts on a Wattbike Pro (UK) separate by a 1-minute semi-active recovery. Results The intra-day and inter-day typical error of estimate (TEM) for peak velocity measured during the CMJ ($0.12, \pm 0.3$ and $0.12, \pm 0.3$ m.s⁻¹) and coefficient of variation (CV) (3.6, ±1.0 and 3.6, ±0.9 %) were small and intra-class correlation (ICC) were very large (0.90 and 0.91 respectively). Intra-day and inter-day TEM for mean power measured during the CMJ ($297.0, \pm 76.7$ and $404.1, \pm 104.4$ watts) and CV (8.2, ±2.2 and 13.4, ±3.7 %) were small to moderate. Mean power measured during the cycling sprint reported small TEM and CV (respectively $30.5, \pm 7.9$ watts and $3.0, \pm 0.9$ % for the intra-day condition and $33.2, \pm 9.0$ watts and $3.2, \pm 0.9$ % for the inter-day condition). Furthermore, ICCs were very large for the intra-day and inter-day conditions (0.95 and 0.94 respectively). Lastly, for [CK], Intra-day and inter-day TEM and CV were considered as small (respectively for intra-day $32.9, \pm 8.2$ UA and $14.3, \pm 3.8$ and for Inter-day, $65.7, \pm 46.6$ UA and $10.6, \pm 8.2$ %) and ICC were very large (0.99 for both conditions) Discussion Peak velocity assessment during the CMJ, mean power recorded during a cycle ergometer sprint test as well as [CK] monitoring were highly reliable in sub-elite rugby players. Sport scientists working with team-sport players could use these data to track meaningful changes in performance over time and monitor fatigue. Wehbe, G. et al., 2014. Neuromuscular Fatigue Monitoring in Team Sport Athletes Using a Cycle Ergometer Test. Int J Sports Physiol Perform.

INTRA-RATER AND INTER-RATER RELIABILITY WHEN MEASURING HIP, KNEE AND ANKLE JOINT ANGLES DURING SINGLE-LEG LANDING USING SILICONCOACH.

ALMALKI, H., SPARKES, V.

The University of Salford

Background to the study: Landing is a frequently performed task in sports. The landing technique used by the individual has important implications not only for the achievement of the tasks following the landing but also to decrease the forces transmitted to the body and the body's ability to absorb these forces. As a result, the landing techniques used by athletes may increase the chance of Anterior Cruciate Ligament (ACL) injury during landing from a jump. SiliconCOACH is a tool that has been designed to analyse movement and joint position. This software is able to provide immediate objective feedback which can be used in a clinical setting. However, the reliability of using this tool to measure lower limb-joint angles during functional activities, such as a SLL has not been established. Objective: To assess intra-rater and inter-rater reliability when measuring hip, knee and ankle joint angles during single-leg landing (SLL), 30 cm drop jump using SiliconCOACH software. Methods: Twenty subjects, 18 males and 2 females with an average age 24.40 years, participated in the study. Seven reflective markers were placed over specific bony landmarks in lower limb for each subject. Three raters used SiliconCOACH three times to calculate hip, knee and ankle joint angles, during SLL. Results: ICC values of using the siliconCOACH programme to measure hip, knee and ankle-joint angles during SLL for intra and inter-rater reliability were very high and varied from 0.97 to 0.99. The standard error of measurements (SEM) was generally very low and varied from 0.53° to 1.38°. Repeated measurements of ANOVA indicate that there was no significant difference in all measurements P-value was varied from (0.12 to 0.95). Conclusion: The study demonstrated that SiliconCOACH software has high inter and intra-rater reliability for measuring hip, knee and ankle joint angles during SLL in a relatively young and healthy population.

IS JUMPING HEIGHT OF SJ AND CMJ EFFECT MUSCLE ACTIVITY?

ONARICI GUNGOR, E.1, SIMSEK, D.1, YILDIZER, G.1, KIRKAYA, I.2

Anadolu University

Introduction Success in volleyball depends primarily on a player's strength, speed, and endurance, together with his body's peak mechanical power output. Methods The study included 12 male Turkish volleyball players (20.13 ± 1.92 age; 178 ± 4.97 cm; 72.44 ± 6.76 kg; 22.92 ± 1.57 kg/m²; Sports Experience: 9.2 ± 3.4 year; Total Sport Hours/Week: 12 hours: 4 days*3 h per week) from the Faculty of Sport Science. The knee extensor and flexor EMG activity and different vertical jumping [Squat Jump (SJ) and Countermovement Jump (CMJ)] performance characteristics of male volleyball players were measured. EMG sensors were applied and participants performed maximum voluntary isometric contractions (MVICs) of the Rectus Femoris (RF), Vastus Lateralis (VL), Vastus Medialis (VM), and long head of the

Biceps Femoris (BF) muscles before exercise testing. EMG activity was recorded during the SJ and CMJ test (Delsys Trigno, Boston, MA). A wireless 3D inertial measurement unit (IMU) (Sensorize, Rome, Italy) was secured to the trunk at the L5 level by an elastic belt for the determining of jumping height. The CMJ tests were performed in the following order: (a) upright standing posture, (b) making a preliminary downward movement through knee and hip flexion [self-selected, called the preferred position (CMUPREF)], (c) followed by an immediate, forceful extension of the knee and hip joints propelling the subject vertically off the ground and (d) prior to take-off, extending the ankles to their maximum range (full plantar flexion) to ensure proper mechanics (Price, 2005). The squat jump test started from a stationary semi-squatting position with 90° of knee joint flexion and involved only knee extension (Earp et al., 2010). Six jumps (separated by a three min rest) were used to record jumping height. To minimize the effect of arm swing on jump performance, the participants were asked to keep their hands on their hips (Rodacki et al., 2002). The size of linear relation between physical structure and variables of sole was examined by calculating Pearson's coefficient. Discussion Jumping height of SJ (37.72 ± 1.53 cm) and BF muscle activity (19.42 ± 13.34) for the high jumping height have a correlation negatively ($r = -.593$; $p = .055$). Jumping height of CMJ (42.00 ± 0.96 cm) and the VL muscle activity (55.04 ± 44.86) for the high jumping height have a correlation coefficient ($r = -.573$; $p = .70$). According to these data there is a correlation between jumping height and muscle activity, but there is no statistically significant difference. References Price, RG. (2005). APPLICATION OF ACCELEROMETRIC SYSTEM FOR DETERMINATION OF STIFFNESS DURING HOPPING

STRUZIK, A., ZAWADZKI, J., PIETRASZEWSKI, B., ROKITA, A.

University School of Physical Education

Introduction Leg stiffness represents a variable which has an effect on vertical jump effectiveness (Struzik and Zawadzki, 2013). However, currently there are several computation methods, but they do not necessarily yield the same values for leg stiffness. Therefore, it is essential that the simplicity of the equipment used does not affect measurement reliability. The aim of this study is to compare values of stiffness recorded in a laboratory environment and using the Myotest accelerometer during hopping task. Methods The measurements were performed in a group of 30 untrained female students from the university school of physical education. Each study participant performed three sets of 5 hops (3 highest hops were analysed) according to the manual for the Myotest system. Further analysis focused on the test with the highest mean height of hops obtained by each participant. Leg stiffness was determined based on the measurement using the Myotest accelerometer, force platforms and the BTS SMART system for motion analysis. Leg stiffness was determined using the methodology developed by Struzik and Zawadzki (2013) as a ratio of changes in the value of ground reaction forces to the respective changes in the height of the greater trochanter of the femur, separately for the counter-movement (amortization) and take-off phases. Results According to the methodology of Struzik and Zawadzki (2013) mean value (+/- SD) of leg stiffness in the counter-movement phase (Kc) was 14.2 ± 6.4 whereas in the take-off phase, this value was (Kt) 15.2 ± 5.7 kN/m. Furthermore, leg stiffness determined using the Myotest (Km) was 30.7 ± 13.3 kN/m. However, the values show certain relationships that can be described by means of the following equations: $Kc = 0.4286 * Km + 1.0952$ ($R^2 = 0.79$) and $Kt = 0.3726 * Km + 3.8124$ ($R^2 = 0.76$). Discussion The relationships between leg stiffness in the counter-movement and take-off phases and the stiffness evaluated using the Myotest allow for conclusion that, despite the significantly overestimated value of stiffness, Myotest accelerometer can be used for determination of its 'contractual value'. Therefore, this measurement offers only an approximate value that can provide information about changes in leg stiffness e.g. following training. The overestimated value can result both from inaccuracy of determination of contact time and flight time by the Myotest accelerometer (Choukou et al. 2014) and from the use of the equation of Dalleau et al. (2004), which assumes that the movement of the center of mass has a harmonic profile. References Choukou M-A, Laffaye G, Taïar R. (2014). Biol Sport, 31(1), 55-62. CHARACTERISTICS OF ASYMMETRY BETWEEN TAKEOFF LEGS DURING RUNNING AND STANDING JUMPS WITH SINGLE LEG

SUGIYAMA, T., MAEDA, A.

National Institute of Fitness and Sports in Kanoya

INTRODUCTION In basketball, an ability of running single leg jump (RSJ) is a determinant for achieving high competitive activities, because RSJ is frequently used for example rebounding at a higher position. It is known that the athletes have a dominant takeoff leg (D-leg) during RSJ (Schiltz et al., 2009). It has been suggested that drop jump (DJ) and repeated rebound jump (RJ) from standing position are effective training to improve the RSJ ability. Thus, these jumps also have a possibility to improve an asymmetry of RSJ between takeoff legs. The present study aimed to clarify the feature of asymmetry between the D-leg and the non-dominant leg (ND-leg) in jumping variables and kinetics of lower limbs during RSJ and standing jumps. METHODS Seven healthy male collegiate basketball players performed a maximal RSJ, RJ, DJ and squat jump without counter movement (SQJ) using D-leg and ND-leg each three times in random order. The 3-dimensional data and ground reaction force were recorded using 12 cameras infrared motion analysis system (500 Hz) and 2 force platforms (2000 Hz). We estimated jump height (JH), jump index, running velocity (RV), decreasing horizontal velocity (ΔHV), reactive strength (%SQJ) and joint torque of the takeoff leg. We calculated asymmetry index of these variables. RESULTS JH, jump index, %SQJ and ΔHV were significantly higher in the D-leg than ND-leg during RSJ and DJ ($p < 0.05$). The peak torques of ankle and knee were significantly greater in the D-leg than ND-leg during RSJ and DJ ($p < 0.05$). DISCUSSION ΔHV was higher in the D-leg than the ND-leg during RSJ but there were no significant asymmetry of RV. High jumpers generally could jump high as RV was higher within the optimal RV (Greig and Yeadon, 2000). The current results indicated that the asymmetry of RSJ was attributed to the ability to effectively transmit RV to JH. %SQJ were higher in the D-leg than the ND-leg during RSJ and DJ. %SQJ which estimated a SSC ability indicated a factor to jump high (Ritzdorf, 2009). The ankle and knee torques were greater in the D-leg than the ND-leg. It is important to jump high that mechanical output about the plantarflexion and knee extensor reached large during DJ (Bobbert et al., 1987). The asymmetries between the legs during RSJ and DJ were attributed to whether the plantarflexion and knee extension torque were greater generated. These findings indicated that DJ may be useful for improving the asymmetry of RSJ. REFERENCES Bobbert MF, Huijing PA, van Ingen Schenau GJ. (1987). *Med Sci Sports Exerc*, 19(4), 332-338. SHORT-TERM ADAPTATIONS TO COMPLEX TRAINING ON SPRINT AND VERTICAL JUMP IN TRAINED ATHLETES: A META-ANALYSIS.

FREITAS, T.T., MARTINEZ-RODRIGUEZ, A., CALLEJA-GONZÁLEZ, J., ALCARAZ, P.E.

Universidad Católica de Murcia; Universidad del País Vasco

Introduction In most sports, the capacity to maximize power production is fundamental and the improvement of sprint and vertical jump (VJ) are important goals. Recently, Complex Training (CT) has emerged as a training method aimed at developing athletes' strength and power. It consists of alternating similar heavy resistance exercises with plyometrics/power ones, set for set, in the same session [1, 2]. In trained athletes, little is known about the short-term adaptations to CT. Hence, this meta-analysis aimed to investigate to what extent CT might improve athletes' sprint and VJ performance. Methods 5 studies (8 CT intervention groups) were included regarding sprint adaptations and a total of 6 studies (8 CT groups) were included concerning VJ. Inclusion criteria: 1) at least one CT intervention group; 2) training protocols ≥ 4 -wks; 3) sample of trained athletes; 4) sprint or VJ as an outcome variable. Mean \pm SD and sample size data were extracted from all included papers. Effect size (ES) of the intervention was calculated by the pre- and post-intervention differences in CT-trained participants. For controlled trials, the ES of the CT was also calculated by the difference in performance after the intervention between CT-trained and CG. Results Significant pre-post increments in sprint and VJ performance ($p<.05$) after CT and also between intervention and CG ($p<.05$). Subgroup analysis indicated that the duration of intervention (≥ 6 -wks; $p<.05$) was the only potential moderating factor explaining the differences found in sprint time. On VJ, intracomplex rest interval (ICRI) (≥ 3 min; $p<.05$) was the one factor potentially explaining the differences obtained. Age, skill level, type of jump or sprint testing, exercise characteristics and sport modality didn't show statistical significance. Discussion The main conclusions indicate that CT is an effective method to increase both sprint and VJ performance in trained athletes. Regarding sprint, longer durations of intervention (≥ 6 weeks) possibly explain pre-post differences, supporting previous findings with different resistance training programs [3]. On VJ, the main moderating factor was the ICRI, with intervals longer than 3 min resulting in higher gains in CMJ height. This finding is in line with previous research [4] and supports the idea that the balance between fatigue and potentiation is not favorable when short ICRI are provided [4]. References 1. Ebben WP. IS THE REDUCED SPIKE-JUMP PERFORMANCE IN ELITE FEMALE VOLLEYBALL PLAYERS DETERMINED ONLY BY SEX DIFFERENCES IN ANATOMY, STRENGTH, AND POWER?

FUCHS, P.X.1, MENZEL, H.J.2, VON DUVILLARD, S.P.1,3, WAGNER, H.1

1 University of Salzburg, 2 Universidade Federal de Minas Gerais, 3 St. Cloud State University

INTRODUCTION: Strength, power, and anatomical differences between women and men are well known. However, in complex movements like the volleyball spike-jump, sex differences in performance may be due to technique. The aim of the study was 1) to detect sex dependent differences in kinematics, kinetics, and muscular activation patterns in the volleyball spike-jump and their impact on performance and 2) to propose sex specific training adaptations based on results of the study. **METHODS:** Fourteen female and male elite volleyball players performed spike-jumps with maximal jump height (JH). The subjects had to spike a volleyball suspended on a rope from the ceiling. Data was collected through a Vicon motion capturing system (Vicon Nexus 1.8) with eight MX13 cameras (250Hz) utilizing a cluster marker set, two AMTI force plates (2000Hz), and surface EMG (2000Hz) on five lower body muscles. A full body 3D-model was programmed in Visual3D for data filtering, calculation of kinematics and the center of mass (CoM), vertical and horizontal forces as well as for EMG rectification, filtering, and peak normalization to determine muscular activation patterns. **RESULTS:** Females approached the spike-jump significantly ($P<0.05$) slower with a shorter penultimate step compared to men. In females, we measured a lower maximal horizontal force and a greater jump angle from the first contacted force plate. Both correlated negatively with the approach speed and JH. Female participants had higher vertical CoM during approach, less reduced joint angle and smaller range of motion in the hip and knees during the last step, resulting in shorter acceleration distance and lower maximal joint velocity in the hip and knees. Differences in activation timing, mean activation, and the occurrence of maximal hip and knee velocity correlated with the approach speed and JH. Furthermore, greater time difference between right and left foot at the take off in female participants contributed to lower JH. **DISCUSSION:** The results suggest that differences in JH cannot be referred only to strength abilities but also to technical skills. The approach phases before the actual upward motion seem to have a great impact on the jump performance. They revealed numerous differences between women and men and can be expected to respond well to training intervention. Increasing approach speed and acceleration distance seems to be beneficial. To convert horizontal approach speed into vertical momentum, minor adjustments in the jump angle and muscular activation may be necessary, especially in the right leg (right-handed players).

EFFECT OF A MOUNTAIN HALF-MARATHON RACE ON VERTICAL JUMPING MECHANICS

BOUDOLOS, K., ROUSANOGLOU, E., BOGDANIS, G., PAPPAS, A., NOUTSOS, K., VAGENAS, G., BAYIOS, I.

National and Kapodistrian University of Athens Greece

Introduction The mountain half-marathon (MHM) distance is of particularly increasing popularity among runners (Running USA's Annual Half-Marathon Report 2014) most likely because it allows the long distance challenge with lower training load than marathons or ultra-marathons. Although a variety of biological fatigued parameters has been studied after long distance running, there is notably scarce information about the changes of jumping mechanics (Millet, 2011). The purpose of the study was to examine the changes of counter-movement jumping (CMJ) mechanics after a mountain half-marathon (MHM) race. Methods Twenty seven runners (41.3 ± 3.8 yrs) who completed a MHM (23.5 km, positive altitude 1007,5 m), performed CMJs (forceplate Kistler:9286AA, 750 Hz) before (Pre) and at 2 time points after the race (Post 1 and Post 2). Analysis included the ground reaction force (GRF) variables of instantaneous mechanics and GRF ensemble averaged curve mechanics for displacement, vertical force, anterior-posterior force, velocity and power. Differences were tested with repeated measures ANOVAs followed by pairwise comparison among Pre, Post 1 and Post 2 ($p< 0.05$). Results Overall there was lowering of jump height (Post 1 -4.1% $p>0.05$, Post 2: -7.9% $p <0.05$) with significant reductions in CMJ instantaneous mechanics. The eccentric changes preceded the concentric ones, Fz peaked later during contact time and Fx was reduced throughout contact time. The ensemble averaging curve analysis revealed an altered force-velocity relation and time intervals of significant pre-post differences for the

examined time-curves and displacement-loops. Discussion The MHM race changed significantly the CMJ mechanics with notable differences in the timing as well as the magnitude of the examined instantaneous and ensemble averaged mechanics. The absence of significance hump height decrease may be attributed to post-activation potentiation. The finding that the eccentric changes preceded the concentric ones may be associated to the impact of the intense eccentric muscular action imposed during the downhill sections of the mountain race. These changes are most likely due to peripheral neuromuscular fatigue (Martin et al. 2010), as a combined result of the race duration, the altitude inclines and declines, as well as, the variable racing terrain. KINEMATIC AND DYNAMIC ANALYSIS OF POWER CLEANING - FUNDAMENTALS OF A PERFORMANCE DIAGNOSTIC TOOL TO DETERMINE JUMP PERFORMANCE.

KURZ, G., MAURUS, P., HOFFMANN, M., STEIN, T.

Karlsruhe Institute of Technology

Introduction To determine jumping abilities in team sports and athletics, mostly isometric strength test and vertical jumps (e.g. CMJ, SJ, DJ) are performed. However, the gained results can only partially be transferred to training settings. Hence, coaches and athletes need more detailed information to align training. Exercises from the Olympic weightlifting (snatch and clean) have similar force-time curves to jumps (Corlock et al., 2004; Garhammer, 1993). Thus, the aim of this study was to analyse the kinematics and dynamics of the snatch and clean and to detect potential correlations between performance-determining parameters of jumping and power cleaning Methods 11 athletes (4 female, 7 male, age 26+/-4yrs) performed vertical jumps (CMJ and SJ with arms akimbo), power cleans at 60, 70, and 80% of 1 RM and maximal isometric contractions in a leg press with a knee angle of 110°. The kinematics of the jumps and the power clean movements were recorded with Vicon cameras (200Hz) and the dynamics were measured with two AMTI force plates (1000 Hz). Based on these data, joint angles and moments in the sagittal plane of the knee, hip, and ankle joints were calculated. Correlations between the different variables of the power clean, the jumps, and the isometric leg press were analysed using bivariate Pearson correlation. The difference in dynamics and kinematics due to the weight conditions in power cleans and CMJ, and in power cleans and leg press were analysed via univariate ANOVA. Results Increasing weight in power clean, Fmax ($r=.707$, $p=.008$) and Fexpl ($r=.588$, $p=.029$) showed significant correlations to CMJ height. No significant correlations were found between isometric Fmax in leg press ($r=.309$, $p=.178$) and CMJ height. Power cleans The differences between dynamic (max. power output) and kinematic (max velocity of the bar) ($r=.576$, $p=0.032$) of the power clean indicate that the optimal training weight should be set at 70% of 1RM. Discussion Our results serve as basis for the development of performance diagnostic tools which gives coaches and athletes the possibility to align their training purposefully and efficiently. Moreover, with the help of future training intervention studies, detailed statements can be made for optimal training weight. A deeper understanding of the source of the force generation in ankle, knee, and hip angle might improve diagnostic tools, possibly including the analysis of individual muscle potentials. Mini-Orals**MO-SH08 Psychology: Mixed Session****KNOWLEDGE OF PHYSICAL ACTIVITY RECOMMENDATION AND STAGES OF PHYSICAL ACTIVITY BEHAVIOR CHANGE**

ABULA, K.

Technical University of Munich

Objective: Based on Trans-theoretical Model, the current study aimed to investigate the association between an individual's knowledge of PA recommendation and PA behavior change. Methods: Three separate studies were conducted: in the first study, Physical Activity Stage of Change Questionnaire was translated and validated among 304 Chinese university students; in the second study, Chinese university students' knowledge of international PA recommendation, PA stage distribution and self-reported PA level were surveyed with a large sample of 10022 students and the association among knowledge, PA stages and PA level were explored in a cross-sectional design; in the third study, the effect of knowledge of PA recommendation on PA behavior change was tested in a randomized controlled experimental design with a sample of 308 students. Results: It was found that Chinese version Physical Activity Stage of Change Questionnaire has good psychometric properties; Only 4.31% of the students correctly recalled the international PA recommendation; only 20.30% of the students meet recommended level of PA, with 10.8% of them in the stage of Pre-contemplation, while 33.6%, 25.9%, 10.2% and 19.5% are in the stages of Contemplation, Preparation, Action and Maintenance respectively. Non parametric Mann Whitney U test result indicated that those with the knowledge of PA recommendation have significantly higher PA stage of change than those without knowledge. Intervention design of presenting PA recommendations to students without the knowledge of PA recommendation brought about significant shift in students' PA stages of change. Conclusions: Knowledge of PA recommendation is significantly associated with PA stages of change and knowledge of PA recommendation is able to bring about significant positive shift in PA stages. But subsequent further analysis illustrated that the degree of change depends on the baseline stage of an individual, those in their earlier stages such as Pre-contemplation benefit more from the exposure to the recommendation compared with those in their higher stages.

EFFECTS OF USING THE MOBILE MOTION ADVISOR IN PHYSICAL EDUCATION LESSONS: MOTIVATION AND AMOTIVATION

PREUSCHL, E., SCHERMER, T., TAMPIER, M., KORNFEIND, P., BACA, A.

University of Vienna

INTRODUCTION According to Ntoumanis (2001), a way to improve intrinsic motivation of students in physical education (PE) is to emphasise improvements based on self-referenced standards, which gives them a feeling of competence. To test motivational effects of a sports app, Preuschl et al. (2015) set up a virtual game - Beat my Activity (BMA) - to be played simultaneously to sports games using a mobile feedback system comprising a smart phone and a stride sensor - the Mobile Motion Advisor (MoMA). BMA incorporates automated feedback based on the individual capabilities and gives everyone in a heterogeneous group of students the chance of winning.

METHODS By using a German version of the SMS-28 test for PE (Granero-Gallegos et al., 2014), the motivation of the students of two classes was measured at the beginning and the end of a semester. Only data of individuals who filled out the questionnaires at both instants is presented here. The intervention group (IG, n=12, age=16±0.7yrs, body mass=75±22.5kg) played BMA simultaneously to small sided games during their PE classes. The control group (CG, n=17, age=16±0.8yrs, body mass=69±18kg) had their normal PE lessons. Both classes were taught by the same teachers. In the SMS-28, questions are answered on a 7 scale level. Each item is related to one of the three factors that are measured: amotivation (4 items), extrinsic (12 items) and intrinsic motivation (12 items).

To see if differences in the changes of the students' motivation over the course of one semester between the IG and the CG occur, an analysis of variance with repeated measures was performed on the sum of items per factor using SPSS 22 (SPSS Inc., Chicago, Illinois). **RESULTS** The analysis of variance with repeated measures did not reveal significant differences ($p < 0.05$) on the state of motivation between IG and CG. The average of the sum of items measuring amotivation rose from 9.94 to 11.4 in the CG and sank from 10.3 to 9.3 in the IG. Extrinsic motivation sank from 40.1 to 37.1 in the CG and from 51.7 to 47.0 in the IG, and intrinsic motivation sank from 46.8 to 41.2 in the CG and rose from 59.2 to 60.0 in the IG. **DISCUSSION** The virtual game BMA is played simultaneously to a real game. As the BMA's rating of the individual efforts is communicated through a handheld device only, it might not be as valuable for the individual as the respect perceived when scoring a goal. Using the MoMA over a semester might therefore not alter the state of motivation of a class of high school students.

THE ASSOCIATION BETWEEN PHYSICAL ACTIVITY, FITNESS AND BODY IMAGE IN ADOLESCENCE AND YOUNG ADULTHOOD - AN EIGHT-YEAR FOLLOW-UP STUDY

GESTSDOTTIR, S., SVANSDOTTIR, E., SIGURDSSON, H., ARNARSSON, A., OMMUNDSEN, Y., ARNGRIMSSON, S., SVEINSSON, TH., JOHANSSON, E.

University of Iceland

Background: Body image dissatisfaction has been linked with a range of adverse psychosocial outcomes in both sexes and has become an important public health issue. Dissatisfaction with one's body has been found among all body sizes. From adolescence to young adulthood individuals go through major developmental changes, which are often accompanied by increased awareness of physical appearance. **Aim:** The aim of current study was to examine if physical activity and fitness relate to body image differently across sex and age. **Methods:** Same participants were measured initially at age 15 (n = 385, 190 females and 195 males) and again at age 23 (n = 201, 92 females and 109 males). Physical activity was assessed objectively, fitness both objectively and subjectively, and body image with Offers Self-Image Questionnaire. Structural equation modeling was used to examine the association between physical activity, fitness and body image; covariates included skinfold thickness, body mass index, socioeconomic status, anxiety, and depression. **Results:** No change was found in body image from adolescence to young adulthood, within sex. Physical activity and aerobic fitness decreased from age 15 to age 23 within sex. Fewer reported their fitness as good or excellent at follow-up than did so at baseline. Factors associated with body image in adolescence were self-reported fitness and depression among females and for males it were skinfold thickness and aerobic fitness. In young adulthood self-reported fitness, depression and body mass index associated with female body image, whereas skinfold thickness, depression, body mass index and self-reported fitness did so among males. **Conclusion:** Results suggest that the relationship of physical activity and fitness to body image is not fixed across this critical age period. Therefore, intervention methods needed to improve body image might need to be tailored to young peoples' age and sex.

CAN MUSIC BOOSTS YOUR BRAIN AS SPORT? COMPARING DRUMMERS, NO-DRUMMER MUSICIANS AND ATHLETES

Università degli studi di Roma Foro Italico

Introduction Both playing sport and a musical instrument seem to produce plastic reorganization of the brain, which affects sensory-motor cognitive functions (Pascual-Leone, 2001; Erickson et al., 2015). The benefits of sport have usually been associated to the aerobic fitness (Erickson et al., 2015); on the other hand, playing music requires a variable amount of aerobic expenditure, depending on the instrument played (De La Rue et al., 2013). Therefore, the advantages on sensory-motor cognitive functions may differ, being minimum for players of static instruments (e.g. piano and violin) and maximum in drums players, since their aerobic costs are similar to those of athletes. To test this hypothesis we compared brain activity and behavioral performance of high-level athletes, drummers and no-drummer musicians using a perceptual decision-making task during electroencephalogram (EEG) recording. **Methods** We enrolled 48 healthy young adults (age 29±5 yrs.) equally divided into four age-matched groups: high-level drummers, non-drummer musicians, athletes and controls (non-athletes and non-musicians). Musicians and athletes were matched for years of practice. Participants performed a visual Go/No-Go task, and their cortical activity was recorded by a 64-channel EEG. Event-related potentials (ERP) and behavioral performance (response time and accuracy) were analyzed. **Results** Behavioral results showed that drummers and athletes were faster than other groups. At ERP level, the pre-stimulus activity in motor-related regions was larger in athletes than musicians and controls. After stimulus onset, drummers significantly differed from the other groups, showing the largest prefrontal positivity (pP1), an ERP component related to the stimulus-response mapping process. **Discussion** Drummers and athletes showed comparable response time, likely due to similar high-energy expenditure. ERP results suggested that this behavioral advantage might be mediated by different cortical processes: athletes showed stronger motor preparation before stimulus onset, whereas drummers showed more intense sensory-motor mapping processes after stimulus onset. **References** De La Rue, S. cal activity, brain, and cognition. Current Opinion in Behavioral Sciences, 4, 27-32. Pascual-Leone, A. (2001). The brain that plays music and is changed by it. Annals of the New York Academy of Sciences, 930(1), 315-329. Contact v.bianco@uniroma4.it

PREDICTION OF EXERCISE IMAGERY ON VITALITY: THE MEDIATING EFFECT OF BASIC PSYCHOLOGICAL NEEDS AMONG COLLEGE STUDENTS

CHEN, J.Y., CHI, L.K.

National Taiwan Normal University

Introduction There has been increased interest and research given to the role of imagery in exercise (Giacobbi et al., 2005). Hall (1995) proposed that imagery may influence exercise participation through its effects on motivation. From the self-determination theory perspective, events that satisfy the basic needs provide the energy to maintain or enhance vitality. Therefore, the aim of this study was to examine whether the prediction of exercise imagery on vitality is mediated by basic needs among college students. **Methods** The participants were 189 college students (95 males, 78 females, mean age 19.74 ± 1.24) recruited from 3 universities in Northern Taiwan. Participants were requested to complete Exercise Imagery Questionnaire (Hausenblas et al., 1999) and Psychological Need Satisfaction in Exercise Scale (Wilson et al., 2006) and Subjective Vitality Scales (Ryan & Frederick, 1997). **Results** The results showed that exercise imagery positively predicted subjective vitality ($R^2=20\%$) and basic psychological needs (autonomy $R^2=30\%$, competence $R^2=27\%$, relatedness $R^2=18\%$). In addition, in terms of the mediating effect of basic psychological needs, the prediction of exercise imagery on subjective vitality was only mediated by competence but not relatedness and autonomy. **Discussion** According to these results, exercise imagery predicted subjective vitality. Moreover, one of the basic needs, competence, played as a mediator. In other words, exercise imagery positive influence college student competence and then positive predicted their subjective vitality. The results of this study suggested that exercisers will be encouraged using exercise imagery to enhance competence and subsequently to enhance their subjective vitality. **References** Giacobbi, P. CHARACTERISTICS OF AUTOBIOGRAPHICAL MEMORIES IN ATHLETES COMPARED NON-ATHLETES

OKUDA, A., NAKAGOMI, S., SUZUKI, M.

Biwako-gakuin University, University of Tsukuba, University of Gifu

Introduction Current behaviors might be understood and even defined by analyzing autobiographical memories such as "formative images" and "proto-experiences in sports." This study aimed to clarify characteristics of athletes' autobiographical memories by comparing them to those of non-athletes, and to investigate the role that autobiographical memories play in athletes' identity development and commitment toward sports. **Methods** Participants were 230 university student athletes who had participated in competitive athletics for an extended period of time (athlete group) and 141 university students (non-athlete group). Self-administered semi-structured questionnaires were distributed to participants. Questions focused on the content of formative images and memorable childhood play experiences, as well as the impact of proto-experiences in sports on one's current self. **Results & Discussion** Content of formative scenes: While nearly 50% of formative images reported among the athlete group comprised various types of play and physical activity (formative images), over 50% of those reported among the non-athlete group were simple or generic scenes. Formative images recalled by the athletes were likely to involve their participation in the scene, but this element was largely absent from the non-athletes. Content of memorable childhood play experiences: Responses were evaluated based on how "space" and "dynamism" were expressed in them. Many of the athletes reported that they engaged in competitive and highly active physical activity from early childhood, which coincided with their reported formative images. The association of these early experiences suggests a potential developmental path into later participation in competitive sports. Influence of proto-experiences in sports on one's current self: Among athletes, the influence of early memorable sports experiences on their current selves was reported to be "inspiration/continued interest" (17.0%), "aspiration/motivation" (22.2%), "perseverance/improved achievement" (14.3%), and "enjoyment" (18.7%). It seems possible that these childhood experiences were driving forces behind athletes' engagement with competitive sports later in their lives. However, many (39%) non-athletes reported an "unknown" linkage between their proto-experiences in sports and some current involvement with sports. Nearly 10% of the non-athletes even reported some negative feelings about continuing sports activities, going so far as to say that they give sports a "wide berth" in their current lives. **References** Okuda A. & Nakagomi S., Suzuki A (2015) Analysis of the proto-scenery in the autobiographies of top athletes. *Bulletin of Biwako-Gakuin University Biwako-Gakuin College*, 6:69-78. PREDISPOSITION TO BIGOREXIA AND EXERCISE ADDICTION: A COMPARISON BETWEEN SPORT SCIENCES STUDENTS AND OTHER STUDENTS

FEZZARDI, C., DELMONTE, V., CALI, S.

University of Milan

INTRODUCTION The Bigorexia (or Reverse Anorexia), is part of Body Dysmorphic Disorders. Subjects who suffer of Bigorexia are disappointed about their body dimensions and their muscles. Sports people and bodybuilders are more involved in this problem than other categories. A 2014 research (Bo et al., 2014) points out that bigorexia is often linked to exercise addiction and it may influence the choice to attend the University of Sport Sciences. The aims of this work are: 1- evaluate if Milan Sport Sciences students suffer of bigorexia in comparison with a group of students of Biology. 2- verify if there are any associations between bigorexia and exercise addiction between the two groups. **METHODS** 100 students of Sport Sciences and 102 of Biology responded to 3 questionnaires: MDDI for bigorexia (Hildebrandt et al., 2006), Veale test (De Coverley Veale et al., 1987) and Zaitz one (Zaitz et al. 1989) for exercise addiction. Mann Whitney Rank sum test was used to evaluate the significant differences between the groups. **RESULTS** 9% of Sport Sciences students are at risk of Bigorexia against 1.9% of Biology students ($P<0.05$). Among potential bigorexia predisposed students 63.6% are at risk of exercise addiction ($P<0.05$). Analyzing only the exercise addiction test, it is noticed that 42% of Sport Sciences students are at risk against 10.7% of Bio-

gy students ($P<0.05$). DISCUSSION The data underline that there is a bigger risk for the group of Sport Sciences both for bigorexia and exercise addiction. Every type of sports people are involved, and not only bodybuilders. Moreover is verified the connection between bigorexia and exercise addiction. The limit of the study is the use of tests, because although they are valid methods of evaluation, they don't guarantee the presence of the illness. For more assurances are necessary individuals interviews between the person and a psychologist. THE ANTICIPATORY STRESS RESPONSE TO SPORT COMPETITION; A META-ANALYSIS OF CORTISOL REACTIVITY

VAN PARIDON, K.N., NEVISON, C.M., TIMMIS, M.A., BRISTOW, M.

Anglia Ruskin University, Cambridge, UK

Introduction Athletes anticipating sport competition regular experience distinct emotional and physiological changes as a result of expected psychosocial stress. Specifically salivary cortisol, an indicator of hypothalamic-pituitary-adrenal (HPA) axis activation, is examined as an objective measure of stress and mediator in attentional processes. Situational factors influencing the cortisol reactivity in laboratory environments are well documented (Dickerson & Kemeny, 2004). However, inconsistent findings are reported in cortisol reactivity in real sport competition. Factors such as gender, age and habituation are attributed to this variation in reactivity. Therefore, the aim of this meta-analysis is to examine cortisol reactivity in athletes anticipating competing in real sport competitions. Method The databases PubMed, PsycINFO, SPORTDiscus and Scopus were searched with key words cortisol, stress and sport competition. Studies were included when cortisol was assessed in saliva, collected before sport competition with a time-matched resting sample. Participant characteristics, mean, SD of cortisol and collection time were extracted. A random effect meta-analysis was conducted based on Hedges g effect sizes of rest to pre-competition cortisol followed by moderator analysis. Results The search identified 1391 records. Based on title and abstract, 1261 studies were excluded. 130 studies were fully screened from which 25 studies with 27 effect sizes and 348 participants (age 23.7±7, 67% male, 51% team sport) were included. Analysis showed a large significant increase in cortisol reactivity ($g=0.85$, $se=0.13$, $p<0.001$). A fail-safe N of 734 studies suggested no publication bias. Males had a trend for greater cortisol reactivity ($g=1.07$) than females ($g=0.56$, $p=.07$). There was an indication that reactivity was reduced in international athletes ($g=0.50$) compared to national ($g=0.85$) and regional athletes ($g=1.12$) albeit not significant ($p=0.3$). There was no significant difference between cortisol reactivity in AM compared to PM competitions ($p=0.25$) and between individual and team sport athletes ($p=0.5$). Regression analysis identified a negative correlation between collection time and reactivity ($Q=6.85$, $p<.01$), indicating greater cortisol reactivity when cortisol is collected closer to the start of competition. Conclusion Anticipating sport competition results in a significant increase in salivary cortisol. However, this effect is reduced when cortisol is collected further away from starting the competition. There is an indication that elite athletes have reduced cortisol reactivity compared to less elite athletes due to habituation, where female athletes tend to have lower cortisol reactivity than male athletes. RELATIONS BETWEEN EMOTIONALLY STRESSED AIMING-TASKS AND REVERSAL THEORY: HEART RATE AND HEMODYNAMIC RESPONSES OF PREFRONTAL AREA STUDY

HOSHINO, S.

Nara Women's University

Introduction In this study, using differential difficulties of darts tasks, we investigated to compare the emotional shift seen in the continuous performance of tasks in psychophysiological indices, and be shown to correspond to the reversal theory of Apter (1984), which has been described in the subjective 2 axis of emotional arousal and hedonic tone. Methods Subjects: 10 college-aged women (19.7 ± 0.7 years). Procedure: authorized the board (distance 237cm, height 237cm) was used as darts (20g). A reference circle for each subjects, was set to a distance of half from the center of the 12 throwing darts. There were two aiming-tasks using differential difficulties of darts targets; 1) Easy (E) task: scoring area was set to 1.5 times of the reference circle radius, which was 5,3,1 points from the center at regular intervals in 3 equally divisions on a concentric circle. 2) Difficult (D) task: scoring area was set to the reference circle, and score range was the same. Physiological indices: Oxygen dynamics of the left forehead value (the prefrontal cortex), the two-wavelength by the semiconductor laser (780nm, 830nm) by using blood oxygen monitor (BOM-L1, Omega Wave), Oxy-Hb, deOxy-Hb Total-Hb were measured. In addition, continuously measured blood flow between the probes (FLOW), blood volume (MASS), blood flow velocity (VELOCITY) (omega flow FLO-CT, Omega Wave, 780nm) was attached. They are all used to determine the average value from the set 1-throw after the beginning of two seconds before until after two seconds of 3-throw, and the amount of change from at rest and its set representative value was calculated. ECG is derived from chest bipolar lead (ECG100C, Biopack Systems) sampling by 200Hz, and the R-R interval was acquired. Psychological indices: Each subject asked their psychological states for the next block [3-throw × 4 sets] in the 'anxiety', 'boring', 'excitement', and 'relax'. Results and Discussion 1. Capture the activation of the prefrontal cortex: A difference to the skin blood flow was observed between the tasks. Prefrontal cortex, regardless of the degree of difficulty is activated. 2. Operation of arousal level: By degree of difficulty of the tasks, arousal level has shown significant difference. D task was said to be a higher activation 'challenge'. 3. Awakening indicator of the autonomic nervous system, heart rate: Slightly correlated with increased anxiety, excitement in the D task was observed. 4. Slightly negative correlation with the increase of boredom was observed in E task. 5. Reversal theory: 'Anxiety' was a negative emotion that occurs when not accompanied by skill in the tasks. Slight association was observed in the activation of the brain and the activation of this emotion. References Apter, M. J. (1989). Reversal theory: Motivation, emotion and personality. viii 208 pp. Doi, H., Nishitani, S., and Shinohara, K. (2013). NIRS as a tool for assaying emotional function in the prefrontal cortex. THE EFFECT OF INCREASING PHYSIOLOGICAL AROUSAL ON BADMINTON SHORT SERVE ACCURACY DURING COMPETITION AND PRACTICE

DUNCAN, M.J., CHAN, K., SMITH, M., CLARKE, N.D.

Coventry University

Introduction Perceptual-motor performance has been suggested to be negatively impacted in situations where physiological arousal is increasing and cognitive anxiety is high compared to when cognitive anxiety is low (Duncan et al., 2016). In such cases, competition has been used to elicit high anxiety and practice low anxiety. The aim of this study was to examine the effect of increasing physiological

arousal on badminton short serve accuracy during competition and practice. Methods Following ethical approval, informed consent and familiarisation, 19 competitive badminton players (10 males; 9 females, mean \pm SD playing experience: 7.3 \pm 3y, mean \pm SD age: 19 \pm 1 y) participated in this counterbalanced study. Players completed the Edwards et al (2005) short serve accuracy test pre and post, the Bottoms et al (2012) Badminton fatigue protocol on two occasions; competition (high cognitive anxiety) and practice (low cognitive anxiety). Heart rate (HR) was monitored throughout and RPE was assessed at 6 points during the 33min protocol. Cognitive anxiety, somatic anxiety and self-confidence were measured pre and post the fatigue protocol and prior to completion of the badminton short-serve test. Results Results from a 2(competition vs practice) X 2(pre vs post) way repeated measures ANOVA revealed a significant main effect for competition vs practice where short serve performance was significantly poorer in competition compared to practice ($P = .025$). Cognitive anxiety intensity increased pre to post fatigue in competition ($P = .001$) but not practice ($P = .521$) conditions. Somatic anxiety intensity increased pre to post for both conditions ($P = .008$). HR was not different between conditions ($P = .460$). RPE was significantly higher in competition compared to practice ($P = .01$). HR and RPE increased with duration of the fatigue protocol irrespective of condition (both $P = .001$). There were no changes in self-confidence across time or condition ($P > .05$). Discussion These results suggest that badminton service performance is negatively affected in conditions where cognitive anxiety is high (competition) compared to when cognitive anxiety is low (practice). RPE was also higher where cognitive anxiety was high (competition) despite no differences in actual physiological load during the fatigue protocol. As such, we propose that the relationship between perceptual change and cognitive anxiety is the decisive factor in predicting decrements in badminton short serve performance References Bottoms L. et al. (2012). J Sports Sci, 30: 285-293. Duncan MJ. et al. (2016). Eur J Sport Sci, 16, 27-35. Edwards B. et al. (2005). Ergonomics, 48, 1488-1498.

INVESTIGATING THE ATTITUDES OF LICENSED ATHLETES IN TURKEY TOWARDS MULTICULTURALISM

ÖZDEMİR, A.S.1, AKGÜL, B.M.2, KARAMAN, M.2, PAKTAŞ, Y.3, KARAKÜÇÜK, S.2

BULENT ECEVİT UNIVERSITY

1: BEU (Zonguldak, Turkey), 2: GU (Ankara, Turkey), 3: GOPU (Tokat, Turkey) Introduction Sports has assumed substantial roles that help prevent conflicts with its pacifist quality, multicultural disposition, international uniform rules and universal practices that enable persons to compete in equal conditions regardless of the differences in their races, religions, languages, and ideologies. In this respect, sports harbors multiculturalism. From this point of view, the aim of this study was to present the attitudes of licensed athletes in Turkey towards multiculturalism and analyze them with regard to some variables. Methods The sample of the study is comprised of 397 licensed athletes in Turkey. The "Munroe Multicultural Attitude Scale" developed by Munroe and Pearson (2006) and adapted into Turkish by Polat (2012) was used as data collection tool. The scale comprising of three sub-dimensions including know, care, and act (Polat, 2012). In data analysis, the descriptive statistics of multiculturalism attitude scores of licensed athletes was put forward. Besides, Independent t-test, One-way ANOVA and Tukey test was used to compare other variables. Results According to the results, there was a significant difference between the attitudes of female and male athletes towards multiculturalism [$t=2.43$; $p<0.05$] and in the sub-dimensions of know [$t=2.93$; $p<0.05$] and act [$t=2.40$; $p<0.05$] according to the results of the t-test conducted for the purpose of testing the impact of the gender of the athletes on their attitudes towards multiculturalism. While it was seen that the attitude of female athletes towards multiculturalism (3.80 ± 0.60) was more positive than that of the male athletes (3.62 ± 0.71). Discussion It was seen that the attitude of female athletes towards multiculturalism (3.80 ± 0.60) was more positive than that of the male athletes (3.62 ± 0.71), which is concordant with various studies conducted for multiculturalism. In related studies (Demircioğlu and Özdemir, 2014), it was seen that females had a more positive attitude than males did. Similarly, females were detected to be more understanding towards differences in political view in a study where the state of being tolerant towards multiculturalism was investigated as regards gender (Çoban, Karaman & Doğan, 2010). A STUDY ON THE CAUSES OF THE SCHOOL SAFETY ACCIDENTS IN KOREA

NAM, Y.S.

Duksung Women's University

In order to identify the causes of the school safety accidents and thus to suggest a prevention policy in Korea, I analyzed the school accident data of total 105,353 cases in Korea obtained from kindergarten to high schools during past two fiscal years of 2012~2013. The accident data of total 105,353 cases were composed of 7029 cases (students: 658,188) for kindergartens, 35,165 cases (students: 2,784,000) for elementary schools, 34,565 cases (students: 1,893,303) for middle schools, and 28,037 cases for high schools. The analysis results of total accidents are as the following. At first, on the basis of their accident-occurring time, those were in the order of 29,868 cases (28.35%) at physical education time, 19,650 cases (18.65%) at lunch time, 18,779 cases (17.82%) at rest or clean up time, 11,199 cases (10.63%) at special activity time, 10,943 cases (10.39%) at class time, 9,071 cases (8.61%) at school event time, and 5,843(5.55%) at the time of going to or out of school. Second, the activities of students occurred at the moments of accidents were in the order of 38,292 cases (36.36%) during physical activity with ball, 21,331 cases (20.24%) during walking or running, 13,620 cases (12.93%) during exercise, 6,680 cases (6.34%) during eating or rest, 4,594 cases (4.36%) during studying, and 6,533cases (6.20%) during other activities. Third, the accident types occurred were in the order of 43,462 cases (41.25%) for fall, 40,390 cases (38.34%) for exposure to physical force, 14,258 cases (13.53%) for collision with a person, 6,680 cases (6.34%) for eating or rest, and 7,3462 cases (6.87%) for other types. Finally, on the basis of accident positions occurred were in the order of 21,770 cases (20.66%) at head, 21,671cases (20.57%) at feet, 20,520 cases (19.48%) at hand, 14,283 cases (13.56%) at leg, 12,466cases (11.83%) at arm, 10,494 cases (9.96%) at tooth, 1,968cases (1.87%) at thoraco-abdominal, and 2,181 cases (2.07%) at other positions. In summary, the highest number of accidents occurred in physical education class

with using ball, the most common type of accident was falling accidents, and the most frequent accident positions were head and feet. In addition, school accidents occurred most frequently in the middle schools. Consequently, in order to prevent accidents, since school safety accidents occurred in physical education classes especially using ball, safety training was required to prevent school safety accidents. Awareness of the safety precaution was needed because accidents happened at critical positions such as head.

JAPANESE STUDENT ATHLETES: HOW TO ARRANGE AN ELITE SPORT CAREER WITH HIGHER EDUCATION IN JAPAN

LEITNER, K.

Rikkyo University

Dual careers as preparation for the 'Second Career' after retiring from competitive sports have attracted great attention in recent years, which can be seen in growing support measures for the combination of higher education with high-performance sports. Japanese athletes are mostly enrolled in higher education anyway, as competitive sports are institutionalized in universities to a great extent. Therefore, this system and organization of elite sports allows to assume that athletes in Japan find adequate environmental conditions supporting dual careers. However, athletes' Second Careers have often been discussed as a severe problem in Japan. This study tries to investigate the Japanese system concerning the compatibility of higher education with high-performance sports to find out about factors causing difficulties for a smooth transition into 'Second Career'. Interviews with Japanese athletes about their educational and sporting life path were conducted to make out system mechanisms and other decisive factors influencing the career development. These career descriptions were analyzed within the framework of system theory by N. Luhmann focusing on the social inclusion of athletes into the social subsystems of competitive sports and education in the same life period. The results generally showed an adequate environment with appropriate conditions for dual careers in higher education in Japan. However, a tendency to the consciousness that student athletes should concentrate on their sports instead of engaging in education became evident. Athletes often benefit special treatment concerning their studies, like admission and even graduation without requiring educational qualifications. With corporate sports, the Japanese system had been able to ensure occupation for athletes, but due to changing conditions, Japan cannot offer enough 'Second Careers' for their athletes anymore. As a result, this study emphasized creating a Japanese way for dual careers by re-thinking educational approaches for athletes and by re-arranging available environmental conditions in university sports in Japan.

A STUDY FOR INTRODUCING THE PHILOSOPHY OF LAO-TUZ INTO OLYMPISM*

KWON, O.1, KIM, D.2, JOO, D.3

1: Pusan National Univ/Busan, South Korea, 2: Yeungnam Univ/Daegu, South Korea, 3: Daegu Catholic Univ/Daegu, South Korea

Introduction As you know, after the beginning of Olympics in 1896 in Athens, the games have gotten one of the best splendid world competitions in the world. Though pursuing the motto of Citius, Altius, and Fortius, the Olympics stress its value of admiring fair play, promoting friendship, and then keeping peace through sports every four years. But different from the hope and argument of it, the Olympics are criticised for being repeatedly stained with drug and match-fixing. I think it is due to the tendency of winner-take-all or only focusing winning. Method In this respect, Tokyo Olympics in 2020 being near at hand, this study is intended to inject the philosophy of Lao-tzu & Chuang-tzu into sports games focusing on only the game itself not the winning. It is the reason that its philosophy teaches us a kind of anthropocentrism of free mind and unrestricted person. Developed by the rules and refined system of modern sports, the worldwide sports games have long-standing chronic diseases such as taking medicine, violence and racial discrimination. Like the words in the thesis of Ohryun Kwon(2008:64), the conflicts between religions and nations cannot be dissolved by any more specific and systemized rules. Lao-tsu argued the chaos of human society basically comes from a false recognition and contradictory social system. Purely real nature in human's is inclined to be interrupted wrong by desire for something. "Lao-tzu admits human beings' basic desires are needed but their ethnics and customs are not desirable.(Bongseon Ryu, Dongkyu Kim, 2013:16)." This statement is reconfirmed in Dongjin Joo(2015) : "There will be a possibility to restore a kind of Western sports humanism through connecting it with the Eastern sports philosophy of ancient Las-tzu & Chuang-tzu." Discussion It is essential that a person's mind or philosophy controls his behavior or attitude for objects. The philosophy of Las-tzu & Chuang-tzu, emphasizing the need of win-win strategy in living, could teach us to have fun and enjoy an game itself not being preoccupied with excessive desire of winning. So it is possible to prevent athletes from indulging in such an unfair practice in any sports as using drugs or match-fixing if endowed with the philosophy of Lao-tzu & Chuang-tzu into sports games. MEANING OF SPORT IN A POSTMODERN CONSUMER SOCIETY

PARK, H.W., KWON, O.R., CHOI, Y.J., NA, J.J.

Chonnam National University

MEANING OF SPORT IN A POSTMODERN CONSUMER SOCIETY Introduction The purpose of this study is to understand what meaning sports has in consumption driven postmodern consumer society. Postmodern consumer society offers opportunities that can fulfill our private desire and representation at maximum on the mass media world. In this society all things are regarded as consumable goods and their consummation has a social meaning. Sports, therefore, becomes a consume good that offers many social meanings. Results & Discussion First we can find sports eroticism as a new meaning from sports consume in a postmodern consumer society. Sports eroticism is spreading more and more in the sports body, sports wear, sports motion etc. Additionally, sports eroticism plays a role as an active way of self-expression of sports participants. The second meaning appears in the conception of sports "Simulation" by J. Baudrillard in the postmodern consumer society. An example is the spread of E-sports that is disguising the real existence of sports by image as representation of sports simulacra. In the sport history it has lost real nature of the sport by scientification, technical innovation, institutionalization, and regulation. In this situation the extended sports simulation circumstance and sports real world has become continually enlarged. Sports simulation may, therefore, suggest not only a new viewpoint of sports but also an opportunity of critical thinking that is an essential character of sports. The third meaning we can find is an account on the diffusion of sports participation and the structural transition of the social stratum. A number of sports participants want to elevate from their social standing through sports participation. The concept of

subordinate imitation and superordinate differentiation of the trickle down theory, Diderot unities, and effect theory explains the circulation of the social stratum and mode through sports participation. Contact lhwpark@jnu.ac.kr

DASEIN AND SPORT

HOGENOVA, A.

Charles University

Abstract: This text aims to shed light on the overall sense of the present time from a daseinsanalytical perspective. Objectification of the body leads to the adoration of performance as the sole purpose of sport. It is important to realize that the body does not stop with our skin, but enters the outside world as a phenomenon in the form of Dasein. It is necessary to understand the body of the athlete in this respect. The essence of Dasein is a temporal dimension in the form of temporality. What is sport? It is an exhibition of the essence of being, which is will to power. Athletes are puppets in the game, which Heidegger calls 'das Gestell' – the requisition of performances in all areas of our lives and sport is the arena where it is most often seen. Of course it is a semantic space for determining the meaning of sport per se. What reigns in this space? 'Die Machenschaft' reigns there – the technical and mechanical solving of problems that occur in our lives, in order to serve pre-existing systems, which plan and control our lives. Our lives and sport as a whole are pre-arranged forces, which in our time are the source of power. What is this power? It is the manifestation of the essence of being of our time, which is 'der Wille zur Macht', something that F. Nietzsche brought to light. The result of this ontological essence is 'die Uebermaechtigung', i.e. a phenomenon of overpowering, which means only one thing: we need to be stronger tomorrow than we are today, and that is how it must remain without disruption, otherwise we will lose our essence of being, we will simply cease to exist, even if people still see and hear us. This is the most important finding of the times in which we live our unique lives. This postulate is the strongest in sport because the fight against doping is only a mask that accelerates the development of new doping agents for which there are no tests. We live in a time of performance. Literature Heidegger, M. Zollikoner Seminare. Frankfurt am Main : Vittorio Klostermann, 1987. Husserl, E. Vorlesungen zur Phänomenologie des inneren Zeitbewusstseins. Halle : herausgegeben von M. Heidegger Freiburg, 1928. Patočka, J. Péče o duši I. Praha : Oikumene, 1996.

SALIVARY MARKERS TO OPTIMIZE ATHLETES' PERFORMANCE: EXPLORING THE USE OF AN ORAL FLUID COLLECTOR

DE RYCK, T., VAN BRUAENE, N.

Labo Nuytinck

Introduction Sport physicians and coaches are constantly trying to increase athletes' performance. Therefore it is important to understand how athletes respond to the weekly training and varying training intensities. For this, salivary biomarkers are gaining more and more interest, with stability and storage issues of the native saliva as the major drawbacks. In this study, we evaluated an oral fluid collector, which consists of a swab for collection and collection bottle with storage buffer, for its use in sport medicine. Material and methods Salivary amylase, cortisol and secretory immunoglobulin A (sIgA) were chosen as key parameters to evaluate the oral fluid collector (OFC). Saliva samples of healthy volunteers were collected both with passive drooling and with the OFC. Using validated assays, concentrations of cortisol and sIgA and the activity of amylase were determined. Furthermore stability of the OFC samples was evaluated at different storage temperatures for different periods of time. To further evaluate the use of the collection device and the interpretation of the assay results a group of athletes was followed during an intensive training program. Results and conclusion Significant correlations were found for all parameters between the native and OFC collected saliva. Furthermore stability of the OFC saliva allowed storage of the saliva samples without the need of freezing or cooled transport. This enables athletes to collect samples at home, after training sessions or at competitions, resulting in high quality monitoring of the athletes' response to increased training load, intensity or stress.

THE SALIVARY AND PLASMA ANDROGEN RESPONSES OF HEALTHY MALES TO A COMBINED STIMULUS

CREWTHER, B.1, KILDUFF, L.P.2,6, FINN, C.3,6, COOK, C.J.4,5,6

1: Institute of Sport, Warsaw. 2: Swansea University. 3: University of the West of Scotland. 4: Bangor University. 5: Australian Institute of Sport. 6: Welsh Institute of Performance Science.

Introduction Androgens are responsive to physical and psychological stress, but no studies have combined these stimuli to acutely modify dehydroepiandrostanedione (DHEA), androstenedione (A4) and testosterone (T) concentrations in different biological fluids. Thus, this study compared the responses of these androgens in saliva and capillary blood to a combined physical and psychological stimulus in healthy men. Methods Twelve males completed three treatments using a randomised, cross-over design; 5 × 10 sec cycle sprints followed by watching a 5-minute aggressive video (EXV), the same stimuli implemented in reverse order (VEX), and a control session. Saliva and capillary blood samples were collected before and after each treatment, equating to ~70 minutes. Saliva was tested for DHEA, A4 and T by immunoassay, with blood sulphated DHEA (DHEA-s), A4 and T tested with mass spectrometry. The within-treatment change scores (log-transformed) were assessed using paired T-tests and the between-treatment responses with analysis of variance. Results The EXV treatment produced positive changes in salivary A4 ($22 \pm 21\%$) and T ($28 \pm 23\%$), whereas salivary DHEA ($101 \pm 44\%$) and T ($33 \pm 16\%$) increased after the VEX session ($p < 0.05$). The DHEA response to VEX was superior to most other salivary androgens. Only the VEX treatment promoted positive blood DHEA-s ($6 \pm 7\%$), A4 ($22 \pm 8\%$) and T ($11 \pm 9\%$) responses. Discussion The combined stimuli increased DHEA, DHEA-s, A4 and T reactivity in saliva and/or blood. The VEX treatment provided the stronger stimulus, possibly as sprint cycling is a potent androgen activator in men (Crewther 2014) and was performed closer to the post-session samples, whereas the video effect is content and population dependent (Crewther 2014). Salivary DHEA was the most responsive (> 3 fold) androgen measure, which could

reflect its role as a precursor to other steroids and the measurement of the biologically active "free" hormone in saliva (Papacosta 2014). Hormonal perturbations have been linked to performance and recovery (Kilduff 2013), so this information could assist with designing warm-up strategies, training workouts and recovery sessions. ANABOLIC HORMONES AND THEIR BINDING PROTEINS CONCENTRATIONS IN FEMALE AND MALE ELITE SOCCER PLAYERS IN RELATION TO PHYSICAL PERFORMANCE

ZEBROWSKA, A., POKORA, I., POPRZECKI, S., JANIKOWSKA, G.

Academy of Physical Education

Introduction In professional sport, the endocrine responses have been shown to be the most important factors contributing to the athlete's performance. The mechanism of endocrine factors release depends on the intensity and duration of physical exercise, but little is known about the relationships between hormonal responses and aerobic and anaerobic maximal power in female athletes. The study aimed to analyzed association between exercise-induced growth hormone (GH), testosterone (T), cortisol (C), steroid hormone binding globulin (SHBG), insulin-like growth factor (IGF-1), insulin-like growth factor binding protein-3 (IGFBP-3), catecholamines (E, NE) and some anabolic-catabolic indexes, i.e.: T/C, T/SHBG, and IGF-1/IGFBP-3 in female and male soccer players. The results were compared to maximal power measured during aerobic and anaerobic maximal exercise tests. Methods Eighteen female (age 19.6 ± 2.6 yrs, training experience 6.9 ± 4.3 yrs) and eighteen male (age 21.8 ± 1.7 yrs, training experience 7.2 ± 2.8 yrs) soccer players participated in the graded aerobic and maximal anaerobic exercise tests. Peak power, maximal oxygen uptake, and peak anaerobic power were measured during the tests. Blood samples were collected for assessment of baseline and post exercise hormones concentrations. Results The elite female and male athletes demonstrated high level of aerobic performance (VO_{2max}: 43.2 ± 4.8 vs. 54.8 ± 3.7 ml/kg/min; p<0.001). In male athletes the maximal exercise test induced an increase in post-exercise GH concentrations (p<0.001), IGF-1 (p<0.05), and GH/IGF-1 ratio (p<0.05). Graded exercise test had a significant effect on serum GH and GH/IGF-1 ratio in female athletes (p<0.05). The steroid hormones, IGF-1 levels and IGF-1/IGFBP-3 ratio were significantly higher after cessation of maximal exercise test in male athletes compared to female soccer players. High-intensity exercise elicited an increase of the norepinephrine level in female subjects (p<0.05). A positive correlation was found between the post-exercise GH and peak power and GH/IGF-1 ratio and maximal aerobic power (r=0.68; p<0.01). Discussion Hormonal status differentially affect physical performance in female and male soccer players. We conclude that growth hormone, GH/IGF-1 ratio, and free fraction of IGF-1 (IGF-1/IGFBP-3) measured during exercise as well as after its cessation might serve as predictors of maximal power and performance in female athletes.

DOES LOW-DOSE TRANSDERMAL TESTOSTERONE APPLICATION IN MALE UNDERCUT THE DETECTION LIMITS IN DOPING ANALYSIS?

SCHÖNFELDER, M.1, HOFMANN, H.2, SCHULZ, T.2, ENGL, T.2, KEMPER, D.2, RAUTENBERG, C.3, OBERHOFFER, R.2, THIEME, D.3

1: NEUROPATH (TU Munich, GER), 2: LPP (TU Munich, GER), 3: IDAS (Kreischa, GER)

Introduction Anabolic androgenic steroids still represent the most frequently abused category of prohibited substances in sports. Especially, in the last years the trend for abuse shifted to low-dose applications to undercut detection limits of analysis. Thus, the aim was to test whether a low-dose testosterone (T) application is detectable in biofluids. Methods Circadian samples of saliva, blood and urine of 11 male volunteers were analyzed for transdermal T application and influence of exercise in comparison to time-matched controls. Participants received two T-patches for 24h, each releasing 2.4mg/day. Salivary samples (DRG, Marburg, GER) and blood serum samples (Greiner, Kremsmünster, AUT) were generated during (0h, 3h, 6h, 9h, 24h) and after application (48h, 72h) and analyzed by specific enzyme-linked immunosorbent assay (ELISA, DRG, Marburg, GER) for whole, free and salivary T. Saliva and urine data were validated by an accredited anti-doping laboratory using gas and liquid chromatography mass spectrometry (GCMS). Statistical analysis was performed by paired t-test and ANOVA for repeated measure followed Bonferroni post-hoc testing for multiple comparison. Correlations were calculated using the Spearman method. The project was approved by the Ethics Committee of the Medical Department of the TUM (Number: 1777/07), registered at ClinicalTrials.gov (NCT02134470), and financed by the "Bundesinstitut für Sportwissenschaft" (Bonn, Germany). Results Circadian controls with and without exercise did not provoke prominent alterations of whole, free, and salivary T. T application for 24h led to a significant (all p<.001) mean increase above controls: total T (median: 5.2 vs. 8.0ng/ml), free T (median: 11.3 vs. 15.6pg/ml), and salivary T (median: 62.4 vs. 99.9 pg/ml). In addition, all three T measurements indicated significant correlations to each other (all r>.538, all p<.001). Comparison with circadian-matched controls showed peaking T-values after 6h and 9h, reaching highest augmentation up to 252.6±123.5% in saliva after 9h. After removal of T patch, all T levels in blood, saliva, and urine returned to baseline within 24h. Different techniques of hormone detection (ELISA, GCMS) indicated significant correlations. Conclusion The results indicate that saliva, blood, and urine exhibit comparable hormone augmentation during low-dose T application, indicating a possible consideration in future doping analysis. However, detection window is restricted to the time of T application. The interindividual variability was high in all biofluids, requiring the use of individual biological passport rather than statistical values.

STRENGTH TRAINING ALTERS EXPRESSION OF GENES INVOLVED IN REGULATION OF STEROID HORMONE AVAILABILITY IN M. VASTUS LATERALIS OF UNTRAINED WOMEN

ELLEFSSEN, S., HAMMARSTRÖM, H., RØNNESTAD, B.R.

Lillehammer University College

Introduction Steroid hormones can substantially affect skeletal muscle morphology and function, as evident from hormone replacement studies (Finkelstein et al. 2013). However, the contribution of exercise-induced circulating steroid hormones in adaptive responses after strength training is debated, with studies showing contradicting results (Rønnestad et al. 2011; West et al. 2010). Recent studies have suggested that local hormone synthesis may play a central role (e.g. Sato et al. 2014). Methods Twenty previously untrained women completed a 12-week full-body strength training intervention. Training-induced strength gains in leg muscles was evaluated as changes in 1RM knee extension. Gene expression of 10 steroidogenic enzymes was measured using qPCR in biopsies sampled at rest from m. vastus lateralis prior to and after the training intervention. Results Strength training resulted in 33 ± 13% increases in 1RM knee extension. Of the 10 steroidogenic genes investigated, strength training increased the expression of AKR1C2 (fold change ~1.3, p = 0.007) and

AKR1C3 (fold change ~1.4, p = 0.003) in m. vastus lateralis. Discussion Strength training increased the expression of the steroidogenic enzymes AKR1C2 and AKR1C3, which are both involved in interconversion of the androgen-receptor ligand testosterone. For example, AKR1C3 transforms androstenedione to testosterone, and increased activity of AKR1C3 in muscle tissue may thus lead to increased bioavailability of active androgens. CORTISOL RESPONSES AFTER A HIGH INTENSITY EXERCISE PROTOCOL IN ADOLESCENT SWIMMERS

MOUSTOGLIANNIS, A.1, PHILIPPOU, A.1, TAMPAKI, M.2, KOLLIAS, L.2, PAPADOPETRAKI, A.2, MARIDAKI, M.2

National and Kapodistrian University of Athens

Introduction Steroid hormones play a key role in modulating the exercise training responses. In particular, cortisol can negatively affect athletic performance, potentially causing fatigue and inflammation, and high levels of this hormone have been associated with impaired performance in elite athletes (Crewther et al., 2011). However, little is known about the cortisol responses in adolescent swimmers after high intensity exercise. The purpose of this study was to determine the salivary cortisol levels in response to a high intensity exercise protocol in adolescent swimmers. Methods Twelve adolescent swimmers (5 female, 7 male, age: 14.4±1.0 Tanner stage 4) participated in the study. Participants performed a high intensity swimming protocol, i.e. 3X200m front crawl at 90% of their best time and the time needed to complete each of the three 200m swimming distance (S1, S2, S3) was recorded. Swimmers were provided with saliva swabs to collect unstimulated mixed saliva before and immediately after the exercise protocol. The swab was placed in the mouth for one minute, then it was transferred into plastic tubes, centrifuged and the resulted saliva sample was analysed. Saliva samples were assayed in duplicate using a commercially available ELISA kit. Differences between the cortisol levels before and after the exercise protocol were analyzed using student's T-test, while one-way ANOVA for repeated measures and Tukey's post hoc tests were used for analyzing swimming performance. Pearson correlation coefficient (r) was used to reveal potential relationship between cortisol levels and swimming performance. Results are presented as mean ± SD. Results Salivary cortisol was significantly higher (1407.4±740.2 pg/ml vs. 4435.9±3039.5 pg/ml p=0.004) after the high intensity protocol. Swimming performance, i.e. the time needed to complete the swimming distance, changed significantly from the first (S1) to the last 200m (S3) (S1: 2,20±0,08 vs. S2: 2,22±0,08 vs. S3: 2,25±0,08 p<0,05). A positive correlation was found between the S3 time and salivary cortisol levels, which marginally failed to reach statistical significance (p<0.05). Conclusion The findings of the present study suggest a significant effect of the exercise protocol on the saliva cortisol levels in adolescents. The relationship found between the increased cortisol levels and decreased performance may imply a causative association of this hormone with the swimming performance that could moderate effectiveness and long term adaptations of training. References Blair T, Crewther, Christian Cook, Marco Cardinale, Robert P. Weatherby and Tim Low Sports Med 2011; 41 (2): 103-123.

MINDFULNESS TRAINING PREVENTS CORTISOL CONCENTRATION ELEVATION IN WHEELCHAIR-BASKETBALL PLAYERS DURING AN INTENSE COMPETITION PERIOD

MACDONALD, L.1,2, MINAHAN, C.1

1: Griffith University, 2: Queensland Academy of Sport

Introduction There is growing interest in the efficacy of mindfulness training to enhance athletic performance (Bernier, 2009; De Petrillo, 2009). Nonetheless, several questions remain unanswered regarding the mechanisms by which mindfulness training may alter cognitive or physiological function. The present study compared changes in salivary cortisol concentration between wheelchair-basketball players undertaking an 8-wk mindfulness training intervention (Mindful group) and a group who did not (Control group). The mindfulness training intervention coincided with an intense 7-wk competition period. Methods Sixteen highly-trained wheelchair-basketball players (5 females) were randomly assigned to a Mindful group (n=8) and a Control group (n=8). The Mindful group completed an 8-wk mindfulness training intervention comprising: 2-wk Introductory period of 8-min meditations + 10 min of exercises, 5 times each wk; 6-wk Intensive period: 45-min meditations + 5 min of exercises, 5 times each wk in addition to regular basketball training and competition while the Control group performed training and competition only. The mindfulness training intervention commenced 3-d before, and finished 3-d after the 7-wk competition period. Salivary cortisol was measured at baseline (BL), every 2 wk during (beginning Wk3, Wk5, Wk7), at the end (End), and 2 wk after (2-Wk Post) the competition period. Results Salivary cortisol concentrations increased in the Control group from BL to Wk3 (p=0.01) and remained elevated compared to BL at Wk5 (p=0.03) and Wk7 (p=0.01), and decreased at End and 2-Wk Post to concentrations no different to BL (p=0.18; p=0.20, respectively). Conversely, salivary cortisol concentrations in the Mindful group did not change from BL when measured at Wk3 (p=0.55), Wk5 (p=0.42), Wk7 (p=0.73), End (p=0.62) and 2-Wk Post (p=0.30). Discussion The present study demonstrates that an 8-wk mindfulness training intervention attenuates the increase in salivary cortisol in wheelchair-basketball players. It has been concluded that mindfulness training may be a beneficial tool for athletes to manage the onset of physiological stress during intense competition. References Bernier M, Thienot E, Cordon R, Fournier JF. (2009). J Clin Sport Psychol, 25(4), 320-333. De Petrillo LA, Kaufman KA, Glass CR, Arnkoff DB. (2009). J Clin Sport Psychol, 3(4), 357-376.

PROLONGED ELECTRICAL MUSCLE STIMULATION INCREASES PLASMA BRAIN-DERIVED NEUROTROPHIC FACTOR IN TYPE 2 DIABETES

MIYAMOTO, T., IWAKURA, T., MORINO, T., IWAMOTO, M., TAKENAKA, M., AKAMATSU, Y., MATSUOKA, N., MORITANI, T.

Hyogo University of Health Sciences

Introduction Electrical muscle stimulation (EMS) is expected to be a candidate for new exercise method in the patients who have a difficulty in performing voluntary exercise. We provided the first evidence indicating that a single bout of EMS could effectively attenuate post-prandial hyperglycemia in type 2 diabetes (T. Miyamoto et al., 2012; T. Miyamoto, Fukuda, Watanabe, Hidaka, & Moritani, 2015) and prolonged EMS could increase muscle strength and cardiorespiratory fitness in healthy subjects (Toshiaki Miyamoto, Kamada, Tamaki, & Moritani). It has been considered that type 2 diabetes is closely related to the onset of nervous diseases such as cognitive impairment and diabetic neuropathy. Recently, brain-derived neurotrophic factor (BDNF) and insulin like growth factor-1 have been considered of exercise-induced neuroplasticity-related proteins. The purpose of this study was to evaluate the effect of prolonged EMS training on plasma BDNF and IGF-1 concentrations as well as metabolic parameters in type 2 diabetes. Methods Fourteen men outpatients with type 2 diabetes participated in this study (Age: 63.4±11.0 years, BMI: 27.0±4.6, HbA1c: 7.7±0.6%). In a randomized crossover trial, patients

were evaluated at baseline and after two 8-week periods (control and EMS training) for body composition, estimated energy intake, physical activity and blood measurements (glucose and fat metabolic parameters, IGF-1, BDNF). Each patients performed 40-min EMS training, 4 days per week, during 8-week EMS training period while maintaining daily lifestyle during 8-week control period. Student's t-test or Wilcoxon test were used to compare the absolute changes of measurements between periods. Results There were not significant differences in estimated energy intake and physical activity between periods. It was found that EMS training significantly attenuated body fat and fasting glucose level ($P<0.05$). Also, EMS training induced significant higher plasma BDNF ($P<0.05$). However, significant differences were not found in the other evaluations. Discussion Our present study showed that prolonged EMS training induced significant lower body fat and fasting glucose level and higher plasma BDNF. This study suggested that EMS can be an alternative exercise method to improve cognitive function as well as metabolism for the patients who cannot perform voluntary exercise. THE INFLUENCE OF THE STATINS IN THE SKELETAL MUSCLE

ANDRÉ, A.

University of Coimbra

The influence of the statins in the skeletal muscle Introduction The skeletal muscle (SM) is a tissue that can adjust to different stimulus. Intake drugs can cause alterations and incapacity to do exercise. Statins interfere with the SM functions is the prescribed medications for prevention and treatment of the cholesterol more used in the world. The side effect is myotoxicity. Creatine Kinase (CK) is a biomarker to evaluate the muscle damage The aim of this study was verify the myotoxicity of the SM without invasive methods, evaluate how the CK change in different groups first that intake statins, second that intake statins and exercise and third a control group, no statins and no exercise. Methods A sample of patients (n=32), with age between 40-65 years was divided into three groups, one that intake statins, second that intake statins plus exercise and third control group. the evaluation was performed in the third group using three different assessments exercise drugs and last exercise and drug. The evaluation started with an exercise prescription during 30 min, blood samples before and after exercise and 24 hours after exercise. An ultrasound was done to evaluate macroscopic and organizations of the fibers gastrocnemius muscle, using a 13 MHz probe. An questionnaire was done subjects. Results The mean CK results were (before exercise, after exercise and 24h after exercise) to the first group that intake drug were, (baseline 95-100 U/L) 114,5±53,4; 117,0±52,3 and 127,2±47,7 U/L (mean ±SD) the cholesterol mean was 203 mg/dl (min 143-max 321), the second group that intake drug and do exercise were, 94,4±43,8; 98,6±43,9 and 111,9±61,9 U/L. The cholesterol mean was 189,4 mg/dl (min 123,8-max 253) The third group in the first evaluation were, 113,7±67,0; 124,8±75,4, and 156,7±86,7 U/L in the second evaluation the results were 86,79±24,6; 87,51±25,6 and 93,24±38,0 U/L, and the last evaluation for the same group were 85,32±24,8; 89,54±25,8 and 89,43±17,4 U/L. The mean of the cholesterol of this group was 194,74 mg/dl (min 157-max 236). In the Ultrasound evaluations the echogenicity of the GM muscle was similar in all groups Discussion Results demonstrated an increase in CK levels in patients that intake statins and 24h after exercise the CK increase, in the first and second group this referred muscle pain that is indicative of a middle myalgia. The third group in the second and third assessments with drug and with drug and exercise respectively the CK decrease related to the first evaluation, with a specific kind of statins have a pleiotropic effect in skeletal muscle with an anti-inflammatory effect (Pella, Rybar, & Mechirova, 2005), is not clear that exercise and statins therapy interact with muscle toxicity (P.Phillips, 2008). Pella, D., Rybar, R., & Mechirova, V. (2005). Pleiotropic effects of statins. *Acta Cardiologica Sinica*, 21(4), 190–198. P. Phillips, R. Haas, (2008) Statin myopathy as a metabolic muscle disease. *Expert Rev. Cardiovasc. Ther.* 6(7), 971-978

FIVE DAY BUCHINGER FASTING AFFECTS ENDURANCE PERFORMANCE AND METABOLISM OF SPORT STUDENTS

BECKER, F.1, OERTZEN-HAGEMANN, V.1, LIMMER, M.2, PLATEN, P.1

Ruhr-Universität Bochum

Introduction: The effects of fasting on physical performance have so far been explored primarily for the intermittent fasting while Ramadan. The idea that training while fasting is the best way to optimize metabolic control and body composition, causes also the risk of a lower performance while training. Aim of the present study was to investigate the effects of a 5-day Buchinger fasting period on endurance performance. Methods: 16 healthy sport students (4 female, 12 male, age: 24.7±1.5y, height: 175.6±6.7cm, body mass: 74.9±9.8kg) participated in the study. Skipping tests and step testswere performed before (BF), while (WF) and after (AF) 5 days of fasting. Step tests were performed at 5 min stages (66, 84, 102, 114, 132, 144, 156 beats per minute) and 1 min break between stages till exhaustion. Lactate threshold, resting heart rate (rHR), total body fat, body weight and maximal reached step test level were determined BF, WF and AF. Results: Body weight decreased during fasting (BF 77.9±7.5 kg vs. AF 74.3±8.9 kg, p= 0.001). Subjects improved maximal reached step test stages (BF: 6.3±1.2 vs. AF: 7.1±0.7, p=0.005) as well as lactate thresholds changed (BF: 9.0±2.8 mmol/l vs. WF 8.1±2.9 mmol/l vs. AF 10.8±2.3 mmol/l, p= 0.008). Furthermore subjects rHR decreased (BF 83±10 rHR vs. WF 72±15 rHR, p= 0.028, BF 83±10 rHR vs. AF 71.±10 rHR, p=0.005) and bpm at 4mmol/l lactate performance for step test increased overall three measurements (BF 98.6±7.7 bpm vs. WF 108.9±33.3 bpm vs. AF 121.7±3.2 bpm, p=0.05). Discussion: Through a 5-day Buchinger fasting there are temporary restrictions during fasting for the aerobic performance, whereas after fasting there are beneficial effects on the physical performance. The results suggest that a fasting period improves the lactic capacity while skipping tests and endurance performance while step tests. It was also shown that there are benefits on the HR after a fasting period. Furthermore we conclude though the fact that lactate threshold is higher in performance after fasting period, athletes can use specific fasting periods in training.

PREVALANCE OF CLINICAL EATING DISORDERS AND RISK OF LOW ENERGY AVAILABILITY AMONGST RECREATIONAL EXERCISERS.

SLATER, J., MCLAY-COKE, R., BROWN, R., BLACK, K.

University of Otago

Introduction Melin et al. (2014) observed only 28% of female athletes with reduced energy availability or Low Energy Availability (LEA) also had disordered eating or an eating disorder. This suggests that diagnosis of disordered eating or eating disorders is not sensitive enough to use as the sole clinical indicator of LEA amongst exercising populations (Melin et al., 2014). Although studies have reported the prevalence of either eating disorders or risk of LEA very few have investigated the prevalence rates of both. Therefore this study aimed to investigate the prevalence of eating disorders and LEA in recreational exercisers in New Zealand. Methods 109 females, and 61 males aged 18-56 years were recruited via gyms and fitness centres throughout New Zealand. Participants all reported that they undertook at least 2.5 hours of moderate physical activity on a weekly basis. Participants completed an anonymous online questionnaire comprising 98 questions from validated eating disorder (Eating Disorder Inventory-3) (Garner, 2004) and LEA questionnaires (Low Energy Availability in Females Questionnaire) (Melin et al. 2014). Results Only one male scored in the medium risk range for the Eating Disorder Inventory Risk Composite (EDIRC) whereas eight females (7.3%, CI, 3.2%, 14.0%) scored in this range. Overall 33.5% (CI 26.5,41.2%) of participants were classified as at risk of LEA. Females had approximately 5.4 times greater probability of being at risk of LEA when compared to males ($p<0.001$). In the present study the vast majority of participants (males 87.5%, 95% CI, 47.3%, 99.7%, n=7, females, 89.8%, 95% CI, 77.8%, 96.6%, n=44) who were classified as at risk of LEA were not considered at risk of an eating disorder. Discussion An EDIRC score in the low risk (low clinical) range (1st-75th percentile) is common among non-clinical samples and does not indicate risk of an eating disorder (Garner, 2004). In line with the findings by Melin et al. 2014, there was a large discrepancy between the number of participants classed as at moderate or high risk of an eating disorder compared with the number classed as being at risk of LEA. This appears to show many participants at risk of LEA do not have a formal eating disorder or disordered eating behaviour. This is an important finding in terms of developing screening tools and education programmes for those at risk of LEA. Further this research also suggests that researchers and health professionals should target their intervention largely to reach the general population of recreational athletes not solely those with eating disorders. A NOVEL METHOD FOR THE DEVELOPMENT OF A GENERAL AND SPORTS NUTRITION KNOWLEDGE QUESTIONNAIRE

TRAKMAN, G., BELSKI, R., FORSYTH, A., HOYE, R.

La Trobe University, Melbourne.

Nutrition can significantly impact athletic performance by increasing exercise capacity, promoting training adaptations, assisting recovery and protecting immune function (Rodriguez, DiMarco, & Langley, 2009). However, research indicates that many athletes fail to follow an appropriate diet (Heaney, O'Connor, Michael, Gifford, & Naughton, 2011). Accordingly, sports dietitians commonly provide education to improve awareness of expert dietary recommendations. Whilst several cross-sectional studies have reported that nutrition knowledge (NK) of athletes is average, with scores on NK questionnaires commonly sitting around 55%, nutrition education programs are rarely evaluated (Heaney, 2011). Furthermore, the correlation between NK and diet quality (DQ), whilst positive, appears moderate at best (Spronk, Kullen, Burdon, & O'Connor, 2014). Nevertheless, it is prudent to note that existing sport NK questionnaires are flawed, and, therefore, previous studies may have underestimated athletes' NK and its relationship with DQ (Spronk et al, 2014). Likewise, the use of inaccurate NK measures may have impaired the development and evaluation of education programs (Heaney et al, 2011). The predominant problems with current tools are that they fail to consider health literacy, are outdated with regards to existing guidelines and have undergone minimal or inappropriate validation (Heaney, 2011). An example of inappropriate validation is the assumption that NK is unidimensional, and subsequent use of Cronbach's alpha to measure reliability. To rectify these problems, we propose a novel eight step methodology. In contrast to previous efforts, the protocol includes (1) detailed conceptualisation of NK, (2) a broad approach to item development, (3) the use of factorial analysis to describe dimensionality and assess appropriateness of reporting NK as a total score, (4) the use of item response theory (IRT) techniques such as Rasch analysis to quantify the relationship between questionnaire items and the 'latent construct', and allow for a shorter questionnaire that includes items with a greater range of difficulty. The results obtained when using classical test theory (CTT) and IRT will be compared and contrasted to determine the best approach regarding which items should be retained. To our knowledge, such a rigorous protocol has not been performed within the discipline of nutrition and dietetics. NUTRITIONAL SUPPLEMENT HABITS AND PERCEPTIONS OF DRAGON BOATERS

ATAEI, L.

University of Nicosia

The consumption of nutritional supplements (NS) is common among athletes for increasing strength, performance, immunologic function, and nutritional resources (I). The purpose of this investigation was to examine prevalence of NS use by dragon boat paddlers; (ii) reasons for use/ non-use; (iii) sources of information regarding NS; and (iv) whether age, gender, performance level influence NS use. Data were collected using semi-structured questionnaires. The questionnaire was completed by 600 elite paddlers (350 M, 250 F) online or at a sporting event or training camp. Data were evaluated by using chi-square analyses. Overall, The large majority (69%; n= 414) of surveyed athletes reported using nutritional supplements, with no difference between female (31%; n=77.5) and male (32%; n=112) athletes. 52% (n= 215.28) of NS user were between 25 to 30 years old. As expected, the most popular NS were multivitamins and minerals (45%), protein-carbohydrate mix (31%), protein (27%), caffeine (22%), other (19%), creatine (15%) and glucosamine (8%). The most common reasons for NS user were to provide energy, support exercise recovery and the immune system. The majority of supplementing athletes (75%) did not have any information regarding their supplements active ingredient, side effects or mechanism of action. Only 21% of NS user knew the recommended supplement dosages and had an opportunity to consult dietary specialists. Despite 16% of the athletes believing that supplements are not required with a balanced diet and can give rise to positive doping violations. However 71% of athletes

requested more information or education regarding NS. 1. Ziegler, P.J., Nelson, J.A., & Jonnalagadda, S.S. (2003). Use of dietary supplements by elite figure skaters. International Journal of Sport Nutrition and Exercise Metabolism, 13, 266-276.

AN EXPLORATION OF PERSONAL TRAINER PRACTICES AND PERCEPTIONS FOR NUTRITION CARE

BARNES, K., BALL, L., DESBROW, B.

Griffith University

Introduction Personal trainers are well placed to provide basic nutrition care, and national regulating bodies are being encouraged to develop guidelines for personal training practices (ICREPS, 2013). In Australia, Fitness Australia developed a scope of practice to support personal trainers to provide nutrition care in line with national dietary guidelines (FA, 2014). However, concerns have been raised about the capacity of personal trainers to provide safe and effective nutrition care (Sass et al., 2007). Therefore, the aim of this study was to explore the context in which personal trainers provide nutrition care, and personal trainers' perceptions of nutrition care in relation to their role and scope of practice in Australia. **Methods** Semi-structured telephone interviews with 15 personal trainers working in Australia. **Results** All personal trainers provided nutrition care, and felt that nutrition was an important component of their role. However, most personal trainers did not use national dietary guidelines to direct the nutrition care they provided, as they were seen as impractical or did not align with the trainers' personal nutritional beliefs. Many personal trainers were unaware of their recommended scope of practice. Some personal trainers felt a gap between the nutrition knowledge they received in their baseline fitness education, and the knowledge required to discuss nutrition with clients. **Discussion** The personal training context is conducive to the provision of nutrition care. The scope of practice limiting nutrition care to the translation of the national dietary guidelines does not appear to have had a substantial impact on personal training practices. **Conclusion** Personal trainers perceived the provision of nutrition care as an important part of their role. Refinement of the scope of practice, or extended nutrition education may be required to ensure that when personal trainers provide nutrition care, they do so in a safe and effective manner. 1 International Confederation of Registers for Exercise Professionals (ICREPS).(2013). EVALUATING RELATIVE HYDRATION WITH HYPOTONIC VS ISOTONIC SPORTS DRINKS: A TALE OF TWO MEASURES

ROWLANDS, D., HOUTHAM, S.

Massey University

The recovery of plasma volume following exercise causing dehydration is an important factor for maintenance of cardiovascular capacity and thermoregulatory function in performance nutrition. The movement of water across a semipermeable membrane by osmosis, such as the luminal epithelium of the upper intestine, should be faster with an ingested hypotonic sports drink, relative isotonic equivalent. Empirical evidence on the matter is equivocal, however. To evaluate the question: does a hypotonic sports drink cause faster hydration than an isotonic?, a systematic literature review and mixed model random effects meta-regression was conducted. Included studies were randomised controlled trials in healthy adults (18-65 y). The studies included an orally ingested or stomach-perfused hypotonic (<275 mOsmol.kg⁻¹) vs. isotonic contrast (275-300 mOsmol.kg⁻¹) with drinks containing carbohydrate and minerals ([Na⁺] <40 mmol.L⁻¹). Drinks were taken at rest, during exercise, or recovery (≥ 1 ml.min⁻¹). The meta-analysis was the sample-size weighted within-contrast factor effect (hypotonic/isotonic), interacted with covariates measurement type and standardised isotonic osmolality. The search utilised Scopus (incl. Medline), Web of Science, and Sport Discus. From 785 retrieved abstracts, 12 publications containing 44 contrasts met the inclusion/exclusion criteria with plasma volume (23 contrasts), plasma D₂O enrichment (1 contrast), and intestinal water absorption (gut triple-lumen segmental perfusion, 15 contrasts) as hydration outcomes. Hypotonic drinks caused a moderate to very large standardised increase in hydration rate, but statistical confidence rendered the overall outcome unclear (meta-regression percent effect on hydration outcome: per -50 mOsmol.kg⁻¹ x-axis change, 6%, 95%CL -4, 18%; per -150 mOsmol.kg⁻¹, 20%, 95%CL -12, 63%). Subset analysis resolved the source of uncertainty as measurement differences. Intestinal water absorption was slower with hypotonic drinks (per -50 mOsmol.kg⁻¹, -9%, 95%CL -19, 2%). In contrast, restoration of plasma volume was almost certainly faster with hypotonic drinks (per -50 mOsmol.kg⁻¹, 17%, 95%CL 9, 25%; >very large). Most segmental perfusion studies were designed to increase fluid absorption with the isotonic by altering the carbohydrate concentration and type (multiple-transportable sugars) to favour jejunal solute drag; indeed, analysis of studies without carbohydrate covariates reduced the isotonic advantage to small (per -50 mOsmol.kg⁻¹, -2.4%, 95%CL -2.3,-2.5%). Inference from segmental perfusion assessment of hydration is limited. Therefore, end-point plasma volume change suggests hydration rate is almost certainly likely to be greater with hypotonic vs. isotonic sport beverages. Funding from Frucor Beverages, NZ.

HYDRATION STRATEGIES AND RISK OF HIPONATREMIA OF RUNNERS IN THE 2015 CURITIBA MARATHON

SOUZA, N.M.F., MOREIRA, M.O., MACHADO, J.F., OLIVEIRA, J.N., SOUZA, K.S., KULNIG, A.M.

FESV (Vitoria, Brazil)

Introduction: Recently, marathon running has evolved from a minority participation sport for elite to a mass participation activity with the expansion of amateur club runners (Williams et al, 2012). After that, reports have emerged of serious illness and death from hyponatremia and the excessive fluid intake is believed to be the primary risk factor (Almond et al, 2005; Siegel, 2015). The aim of this study was to explore the hydration strategies of marathon runners, their source of information, the knowledge about fluid intake and understanding of hyponatremia. **Methods:** Fifty-eight runners of the 2015 Curitiba Marathon (Curitiba, Brazil) answered a questionnaire adapted from Williams et al (2012). Mean temperature and humidity during the race was 18°C and 82%. The questionnaire was composed of questions about planned fluid consumption, volume to be consumed, volume of water and sports drinks (Gatorade) available in the race and the number of stations that volunteers planned to carry out the drink. Furthermore, it was asked for sources of information and understanding of hyponatremia. **Results:** In total, 41.4% had a fluid intake plan. However, 8% planned to ingest a large volume enough to put them at greater risk of hyponatremia (> 3500 mL). Only 4 (7.8%) knew the exact volumes of water and sports drink (Gatorade) available in the course; 58.6% wanted to drink water in all stations. Only 15.5% planned to drink according to thirst. While 52% of the runners had heard of hyponatremia or low sodium levels, only 4 (6.9%) was in fact a basic understanding of its cause and effects. There was no significant difference ($p > 0.05$) in the proportion of experienced runners and inexperienced runners or club runners and nonclub runners who planned to drink more than 3500 mL during the race. Runners with basic understanding of hyponatremia were

experienced runners. There was no significant difference in proportions of club runners and nonclub runners who understood hyponatremia. Discussion: There was a lack of understanding about the proper fluid intake to prevent hyponatremia and their associated risks. Approximately 10% of the runners planned to ingest a volume of fluid which would place them at an increased risk of developing hyponatremia during the marathon. Runners' knowledge of safe drinking strategies and exercise-associated hyponatremia was poorer than the London Marathon runners (Williams et al, 2012). Club runners, who have professional staff, may not be given proper information about fluid intake strategies and the importance of sports drink (Gatorade) for long distance races. Educational interventions are needed to prevent hyponatremia. References Almond, CS et al. (2005). N Engl J Med, 352(15), 1550-1556 Siegel, AJ (2015). Am J Med, 128(10), 1070-1075 Williams, JW et al. FLUID CONSUMPTION HABITS OF ELITE ATHLETES

ARABACI, R.

Uludag University, Faculty of Sport Sciences

INTRODUCTION Fluids are a vital requirement for athletes. All nutrients are important for performance, but has a more critical importance of water. Dehydration and hypohydration can lead to headaches, reduced blood volume, reduced endurance, altered thermoregulatory capability and impaired cognitive and physical performance 1-3. To our knowledge, no studies have examined water intake using the most recently available dietary data of Turkish athletes. Objective of present study was to examine fluid consumption habits of elite Turkish athletes and compared total fluid intake of training and non-training days. METHODS A total of 142 male (mean age 24.5 ± 4.2 years, height 177 ± 11.7 cm and weight 79.1 ± 6.9 kg) and 103 female (mean age 24.8 ± 3.3 year, height 167.6 ± 9.4 cm and weight 58.5 ± 5.6 kg) Turkish elite athletes living in Bursa participated in study. Written questions asked techniques were used for data collection. As data collection tool was administered a questionnaire consisting of two parts. The first part of the questionnaire assessed personal knowledge, the second part assesses water and fluid consumption of subjects. To compare the non-training and training days fluid consumption was used Independent Samples T Test. RESULTS Female athletes in non-training (NTD) and training days (TD) intake water 1066.4 ml/day (47.5%) and 1518.4 ml/day (51.4%), tea 386.1 ml/day (17.2%) and 534.7 ml/day (18.1%), fruit juice 175.1 ml/day (7.8%) and 239.3 ml/day (8.1%), energy drinks 40.4 ml/day (1.8%) and 85.7 ml/day (2.9%), respectively. Male athletes in NTD and TD intake water 1192.1 ml/day (48.4%) and 1653.7 ml/day (52.1%), tea 445.8 ml/day (18.1%) and 568.1 ml/day (17.9%), fruit juice 169.9 ml/day (6.9%) and 241.2 ml/day (7.6%), energy drinks 54.2 ml/day (2.2%) and 98.4 ml/day (3.1%), respectively. Statistically significant differences were observe between NTD and TD fluid intake in both gender ($p < 0.05$). Male subjects consumed 28.9% more fluid in TD (3174 ± 46.3) than NTD (2463 ± 32.1 mL/day). Female subjects consumed 31.6% more fluid in TD (2954 ± 35.4) than NTD (2245 ± 45.2 mL/day). DISCUSSION Adequate fluid consumption, especially water intake is very important for athletes. Athletes have been increased fluid intake in training days. Water is the most increased fluid. This may be related to excessive sweating of athletes during exercise. Drinking sufficient volumes of fluid during physical activity to minimize dehydration is arguably the simplest and most effective means of sustaining physiological function and improving physical performance. EXERCISE WITH NITRATE SUPPLEMENTATION – WHAT IS THE EFFECT ON FAT METABOLISM DURING REPEATED SPRINTS?

RÖHRICH, M.2, MAASEN, N.1,2, FINKEL, A.1,2, BLAU, L.2, LÜTZOW, M.2, JACOB, C.1, MAASEN, M.1

Medizinische Hochschule Hannover, Leibniz Universität Hannover

1 Inst. f. Sport Science; Leibniz University, Hannover 2 Inst. f. Sport Medicine; Hannover Medical School, Hannover Introduction Recently the influence of a supplementation with inorganic nitrate (NO₃-) on physical performance and physiology has been of interest. Especially its beneficial effects on exercise tolerance and performance during submaximal exercise when taken before the exercise. Our aim was to investigate long term effects of NO₃- on fat metabolism during a repeated sprint test when taken during a training period. Methods A group of 17 young (26.7 ± 4.1 y) healthy male athletes ($W_{max} 4.85 \pm 0.7$ W/kg bodyweight) performed an interval training on a cycling ergometer for 3 weeks, 3 times a week in addition to usual training agenda within a placebo controlled double blind trial. 9 (N) participants took a NaNO₃ supplementation of 8.5 mg per kg bodyweight daily and 8 (P) a placebo (NaCl). We tested for repeated sprints in a Double-Wingate-Test before and after training. Physiological parameters, concentrations of free fatty acids [FFA], free glycerol [FG] and total glycerol [GG] in plasma were measured. Triglyceride concentration [Tr] was calculated from [FG] and [GG]. Results There was no significant change in [FFA]. Although [FFA] follows a comparable course pattern, this is similar in both groups before and after training and changes in concentration over testing time are not significant. There is a significant change in the course of [FG] between P and N after training: in all cases [FG] increases towards the end of the test. However, in P there is a significant increase in [FG] during resting time 18 min and 30 min after repeated sprinting, in N a significant decrease in [FG] respectively. [GG], [Tr] and respiratory quotient (RQ) remained similar. Discussion The results suggest a decrease in fat metabolism after training with NO₃-; the increase in [FG] towards the end of the test is smaller for N than for P. But there is no corresponding result in RQ. Although, an interpretation of RQ in terms of substrate metabolism remains questionable under testing conditions due to hyperventilation. Possibly [FG] decreases faster in N than in P during resting time due to an increase in liver perfusion caused by vasodilatation resulting in an increase in transport of FG to hepatocytes and faster elimination of FG from plasma. PROCESS EVALUATION OF THE INTERVENTION 'EXERCISE ON PRESCRIPTION' PERFORMED IN PROFESSIONALS WITHIN PRIMARY CARE, PROFESSIONALS IN SPORTS, AND PARTICIPANTS

COLLARD, D.

Mulier Institute

Introduction Too little exercise leads to a variety of complaints and ultimately to a decrease in health. Promoting sport as an intervention in primary care seems promising to stimulate people to a more active lifestyle and improve their perceived health. 'Exercise on prescription' is one of these preventive interventions that is initiated in the primary care setting. The objective of 'Exercise on prescription' is to encourage inactive people to be physically active and thereby decrease complaints. General practitioners, practice nurses or physiotherapists offer patients a wide range of sport and physical activities. In the Netherlands 'Exercise on prescription' is conducted since 2012. The goal of the process evaluation is to gain insight into the process and the limitations experienced by professionals within primary care with redirecting patients to sport and physical activities (in stead of give them medication). In addition, the research provides insight into which patients are reached, which criteria are applied by professionals and which results are experienced. Also, success factors, limitations and experienced were registered by professionals in sports and participants. Methods To answer the research questions semi-structured interviews with professionals within primary care ($n = 20$) and providers of sport activities ($n = 10$) were held. In addition, participants ($n = 40$) (aged 18-74 years) filled out a questionnaire regarding characteristics, experiences, success factors, limitations and outcome perspectives. Results The results give insight in the criteria that professionals within primary care use to redirect patients. In addition success factors and limitations are described concerning stimulating patients to participate in sports in order to improve their health and decrease medical costs. Also, the results show what is needed according to the professionals in sports and participants to stimulate them to continue to participate in sport and to increase their perceived health. Discussion Based on the results conclusions about the reach, feasibility and the effects on sport behaviour and perceived health as a result of the intervention 'Exercise on Prescription' can be drawn and recommendations for further development can be made. THE EFFECTS OF NINE MATRICES EXERCISE TRAINING ON PHYSICAL FITNESS AND HEALTH IN OLDER ADULTS

OUTAYANIK, B.

Kasetsart University

Nine Matrices Exercise (NME) program is a new alternative exercise that combines aerobic exercise, resistance training and stretching to develop and maintain cardiorespiratory endurance, strength and flexibility in older adults. The purpose of this study was to examine the effectiveness of the NME program on cardiorespiratory endurance, muscular strength, flexibility, agility/ balance, heart rate, blood pressure and body mass index (BMI) among older adults. Thirty healthy Thai elderly volunteers in the age group of 60-75, are part of Kasetsart University aging club and undertook 8 weeks of NME program intervention 5 days per week and 30-60 minutes per session. All the volunteers were measured for resting heart rate, blood pressure, BMI and performed the senior fitness test which consists of the 6-Minute Walk, Chair Sit-&-Reach, Arm Curl, Back Scratch, Chair Stand and 8-Ft Up & Go before and after training. The data was analyzed by using mean, standard deviation and paired samples T-Test. The results revealed that there was significant reduction in heart rate ($P<.01$) and BMI ($P<.01$) before and after training, but no significant difference in blood pressure. There was significant improvement in their cardiovascular endurance ($P<.01$), arm strength ($P<.01$), leg strength ($P<.01$), shoulder flexibility ($P<.01$), lower back/ hamstring flexibility ($P<.01$) and agility/balance ($P<.01$) before and after training. In summary, the NME training protocol produced beneficial changes in cardiovascular and musculoskeletal fitness, resulting in better and more healthy ageing of the older people and they can take an active part in society and enjoy an independent and high quality of life. Also, we concluded this NME program as an alternative physical activity which practical and appropriate to improve and maintain health-physical fitness to older adults.

DANCING IN TIME: FEASIBILITY AND ACCEPTABILITY OF A CONTEMPORARY DANCE PROGRAMME TO IMPROVE HEALTH AND WELLBEING IN COMMUNITY DWELLING OLDER ADULTS.

ASTILL, S., ADDINGTON, C., BRITTON, L.

University of Leeds

Many older adults do not engage in sufficient physical activity (PA), and are known to be at risk of depression and falls. This early-phase study examined the feasibility, and impact of a 10 week contemporary dance (CD) programme on older adults' PA, mobility, sedentary behaviour (SB), depressive state and fear of falling as part of the development of the intervention. An uncontrolled 'pre-post' intervention design was used. Three groups of older (60yrs+) adults were recruited from local community groups between January and December 2015 to participate in a 3 separate, 10 week dance programmes. Each programme comprised 2, 90 minute dance classes per week. Quantitative measures of physical activity (PA), sedentary behaviour (SB), depression, mobility and fear of falling were measured at baseline (session 4) and then at the end of the dance programme (session 20). Weekly attendance was noted, and post-study qualitative work was conducted with participants in 3 separate focus groups, and for all samples a combined thematic analysis of the content conducted. A total of 38 older adults (Mean Age=77.3±8.4yrs, 1M) completed the dance programme (F=37) with the mean number of sessions attended being 12.2±3.5, and mean adherence rate 72.1±20.8%. Of these 38, only 22 (21F, 1M) older adults (M=74.8, SD=8.44) consented to be part of the study. The mean attendance was 14.6 (±2.6) sessions, and mean adherence was 84.3% (±17). Significant increases in moderate (243.2±175.2 vs 305.7±217.9 minutes/week, $p<0.05$) and vigorous (34.5±60.2 vs 51.8±70.6, $p<0.005$) PA were noted, with a significant decrease in sitting time over the weekdays (2299.5±1630.1 vs 2197.27±713.4 minutes/week, $p<0.05$). Statistically significant decreases in the GDS (3.2±3.3 vs 2.1±2.8, $p<0.05$) and FES-1 (27.6±9.9 vs 23.0±8.6, $p<0.005$) scores and the time taken to complete the TUG test (10.1±4.2 vs 7.7±2.8, $p<0.005$) were noted. Qualitative data indicated that all participants viewed the intervention positively, enjoyed dancing, and reported health and well-being gains. The recruitment of older adults, good adherence and favourability across all three sites indicate that a dance programme is feasible as an intervention. Furthermore, a CD programme has the potential to positively

affect the PA, SB, falls related efficacy, mobility and incidence of depression of the participants, but an adequately powered study with additional control groups are required to test this intervention approach further.

BONE MICROARCHITECTURE AND BONE STRENGTH FOLLOWING A 12-WEEK PROGRESSIVE HIGH-RESISTANCE POWER TRAINING IN MOBILITY LIMITED OLDER ADULTS

STEINHAUSER, V., SHANBOGHUE, V., HVID, L.G., CASEROTTI, P.

University of Southern Denmark, University Hospital Odense

Background With increasing age bone health worsens, causing bone fragility and greater risk of osteoporotic fractures, representing a remarkable economic burden for the health care systems. Strength training is regarded as effective intervention to counteract age-related bone deterioration, however power training (high movement velocity and lifted weight) induces higher mechanical strain on bones and was shown to be particularly relevant for bone adaptation (von Stengel et al., 2007). The effects on bone health are generally assessed by dual-energy X-ray absorptiometry (DXA) derived bone mineral density (BMD). Recently, a new high-resolution peripheral quantitative computed tomography (HR-pQCT) technique was introduced. This allows to distinguish between cortical and trabecular bone and to assess bone geometry, densities, microarchitecture and strength, potentially in the early phase of bone formation. The aim of this study was to assess the effect of short-term progressive high-resistance power training in mobility-limited older adults on bone geometry, microarchitecture, densities and bone strength, at the tibia and the wrist anatomical locations. Methods 57 women and men, (75-93 years), were randomly allocated into a training (TRAIN, n = 28) and a control (CTRL, n = 29) group. A 12-week progressive high-resistance power training for upper and lower extremities was performed by the TRAIN group while the control group maintained current life-style. Both groups received pre-post intervention scans at the radius and tibia using HR-pQCT. Results Women increased significantly both failure load ($p=0.028$) and stiffness ($p=0.05$) at the radius, whereas men remained unchanged. When data were analyzed for the whole cohort together, a trend for increase in bone strength (stiffness, TRAIN +2.6%, $p=0.063$), trabecular thickness (TRAIN +4.22%, $p=0.081$), and trabecular separation (TRAIN +3.9%, $p=0.067$) at the radius were observed. No significant changes were seen at the tibia for the whole cohort and after gender stratification. Conclusion 12-week progressive high-resistance power training shows significantly increased bone strength at the radius in women and tendencies regarding the whole cohort. Associations of reduced bone strength in postmenopausal women with previous wrist fractures (Melton III, et al., 2010) underline importance of the improvements following the exercise intervention. Results suggest progressive high-resistance power training to be effective in improving bone health in mobility limited old aged individuals. von Stengel, et al. (2007). Br J Sports Med.; 41(10) Melton III, et al. (2010). Osteoporos Int.; 21(7)

SIDE TO SIDE DIFFERENCES IN DOMINANT VERSUS NON-DOMINANT ARM IN BMD, T-SCORE AND Z-SCORE AND ISOMETRIC HANDGRIP STRENGTH MALES AND FEMALES AGED 40-65 YEARS OLD IN KOSOVA

BOSHNJAKU, A., KRASNIQI, E., KABASHI, A.

University of Gjakova

Introduction: This observational, cross-sectional study, investigates and compares the differences of BMD, T-score, Z-score (DEXA scan) and isometric strength (handgrip) between dominant versus non-dominant arms of 162 subjects aged 40-65 in a developing, low income country such as Kosova. **Methodology:** Bone Mineral Density (BMD), T-score and Z-score at distal forearm regions of both arms, together with the isometric strength Handgrip were evaluated in a total of 162 subjects, out of which 53 Males (average age 55.15 ± 7.12) and 109 Females (54.27 ± 5.1). Additionally, self-administered Nutritional Standard Questionnaire (NSQ) and International Physical Activity Questionnaire (IPAQ) were filled. **Results:** When comparing BMD, T-score and Z-score in dominant versus non-dominant arms in total subjects, results with significant differences were found in total subjects in BMD (0.379 ± 0.09 vs 0.352 ± 0.08), T-score (0.02 ± 1.51 vs -0.52 ± 1.16), and Z-score (0.51 ± 1.3 vs -0.01 ± 0.95). Similar results ($p<0.05$) were evidenced in Females with BMD (0.343 ± 0.07 vs 0.317 ± 0.06), T-score (-0.19 ± 1.47 vs -0.69 ± 1.17) and Z-score (0.75 ± 1.37 vs 0.1 ± 1.01), whereas not significant differences were observed in Males BMD (0.450 ± 0.09 vs 0.421 ± 1.48) comparing to significantly higher results ($p<0.05$) in T-score (0.44 ± 1.48 vs 0.17 ± 1.07) and Z-score (0.751 ± 1.37 vs 0.1 ± 1.01) between dominant and non-dominant arms. When comparing the Handgrip isometric strength test in dominant vs non-dominant arms, significantly higher results ($p<0.05$) were observed in the dominant side in total subjects (30.64 ± 9.32 vs 28.24 ± 8.81), which was the same case ($p<0.05$) in Females (26.75 ± 5.92 vs 24.59 ± 4.7), and also in Males (38.49 ± 9.95 vs 35.74 ± 9.56). When comparing the total subject's BMD, T-score, Z-score and Handgrip based on the PA levels (1, 2, 3) between dominant and non-dominant sides, no significant differences were found between PA1, as well as PA3 ($p>0.05$), whereas significantly differences were found in dominant arms of PA2 level (comparing to the non-dominant ones). **Conclusion:** This study analyses and compares the side to side differences in bone density and muscular force between dominant and non-dominant arms amongst a population which is frequently exposed to diagnostic screenings for age related conditions (aged 40-60). This study helps to understand the background factors that might play a crucial role on diagnostic process.

ACTIVE LIFE STYLE HAS A POSITIVE IMPACT ON MUSCLE AND FAT MASS DISTRIBUTION AS WELL AS ON FUNCTIONAL FITNESS IN OLDER ADULTS

PARAVLIC, A., MARUSIC, U., PISOT, S., GERZEVIC, M., ZERBO-SPORIN, D., PLEVNIK, M., SIMUNIC, B., PISOT, R.

Science and Research Centre, University of Primorska

Introduction: Muscle mass (MM) and strength decrease with age in older adult population and may even accelerated after the age of 65 years. Mankowski, Anton & Aubertin-Leheudre (2015) noted that high levels of adipose tissue and low muscle mass and strength could contribute to a decline in motor function and significantly increase the risk for disability. This study aimed to investigate the influence of the level of physical activity (PA) in both, extremely active (ExA) and extremely inactive (ExInA) elderly subjects on body composition parameters and performance output, with special emphasis on the relationship of MM and fat mass (FM) distribution. **Methods:** The quantity of PA was measured with General Physical Activity Questionnaire (GPAQ) in 3 Slovenian towns on a sample of 443 subjects (EU project PANGEA: Physical Activity and Nutrition for Quality Ageing) from which 36.3 % were men (68 ± 6 years, 174 ± 6 cm; 84 ± 10 kg) and 64.7% were women (67 ± 5 years, 161 ± 6 cm; 70 ± 12 kg). Subjects were further divided in 3 groups by METs (ExInA, Moderate Active and ExA), and age (≤ 64 , 65-70 and 71+ years). Fat free mass (FFM; %), FM (%), MM (kg) and mineral mass (MiM; kg) were assessed by Maltron BioScan 916S bioimpedance analyzer. Gait velocity (Gv; m/s), grip strength (GS; kg) and flexibility were measured by OptoGait system, Jamar dynamometer, and Sit and Reach test (SaR; cm), respectively. **Results:** Two-way ANOVA showed no significant interactions between AGE and METs on body composition (BC) and performance parameters ($p>0.05$). However, there was a significant main effect ($P<0.001$) of

AGE for MiM, Gv and SaR, as well as of METs for FFM ($P<0.001$), FM ($P<0.001$), MM ($P=0.019$), MiM ($P=0.006$), GS ($P=0.019$), Gv ($P=0.001$) parameters. Subsequent comparisons revealed that <64 group had higher values ($P<0.001$) of MiM, SaR and Gv as compared with 71+ group. Furthermore, ExA group had higher values of FFM ($P<0.001$), Gv ($P<0.001$), MiM ($P=0.002$) and MM ($P=0.01$) as compared with ExlnA. Finally, FM values were on average 9.7% higher in ExlnA as compared with ExA ($P<0.001$). Discussion: The level of PA is correlated with BC and functional abilities, which represent an important indicator of general health. These results suggest that higher level of PA has a preventive role in preserving MM and functional abilities with age. In addition, it contributes to a reduction of total FM, which is related to higher levels of disability and mobility impairments in older adults population (Koster et al., 2011). The detrimental effect of physical inactivity on MM in older adults, as it emerges from the present work, emphasizes the importance of continuation active life style in the third age, with a special attention on maintaining/improving muscular strength. IS THERE A DIFFERENCE IN BONE HEALTH BETWEEN MEN AND WOMEN WITH MCARDLE DISEASE?

RODRÍGUEZ-GÓMEZ, I.I, DÍEZ-BERMEJO, J.2, MARTÍN-GARCÍA, M.1, MUNGUÍA-IZQUIERDO, D.3, LUCIA, A.2, SANTALLA, A.3, ARA, I.1

1: GENUD Toledo, UCLM (Toledo, España), 2: UEM, i+12, (Madrid, España), 3: UPO (Sevilla, España)

Introduction McArdle is a genetic disease characterized by an inability to break down muscle glycogen. Hyperkalemia is one common symptom of this pathology, which could potentially influence bone health due to the fact that potassium have opposing actions on calcium excretion (Weaver, 2013). The aim of this study was to evaluate the bone mineral content (BMC) and the bone mineral density (BMD) of men and women with McArdle disease. Methods 18 patients (31.6±7.1 years), 8 men and 10 women of similar age, height and body mass took part in the study. Body composition was assessed using DXA (Hologic QDR Discovery), while physical activity (PA) and quality of life (QL) levels were evaluated by IPAQ and SF-36 questionnaires, respectively. Covariance analysis was performed in order to determine bone differences between genders including body mass, height and age as covariates and T-student test was applied in order to assess PA and QL differences. Results Men showed significantly higher values than women in most of the BMC variables, both at the whole body level (1637 ± 64 vs 1615 ± 57 g) and in several regional levels: legs (402 ± 12 vs 389 ± 11 g), arms (149 ± 5 vs 132 ± 4 g), and trochanter (8 ± 1 vs 7 ± 1 g) (all $p<0.001$). BMD values were also higher in men at legs (1.16 ± 0.02 vs 1.08 ± 0.02 g•cm $^{-2}$) and arms sites (0.74 ± 0.01 vs 0.70 ± 0.01 g•cm $^{-2}$, both $p<0.001$). Men showed 4.5% lower BMD values at femoral neck while women had 3.6% greater levels when compared to reference values (RV) for subjects with similar age without pathologies. Moreover, lumbar spine BMD was 8.2% lower and 2.0% greater (in men and women respectively) (Yang and Shen, 2015). Similar results of PA and QL were found between genders, being regular PA levels within the range considered healthy (>600MET.min.wk $^{-1}$), and QL scores below the corresponding RV (Alonso et al., 1998; Brown and Bauman, 2000). Discussion Although men showed higher values than women in BMC at most of the studied sites and BMD at the arm and legs, bone health in men with McArdle disease seems to be reduced compared to their healthy counterparts while women with McArdle disease showed similar values than gender adjusted RV. Although no differences in the PA and QL among genders were present, more studies in this field are warranted in order to adequately interpret these findings and to better understand the possible mechanisms that could explain these gender differences. MO-PM26 Fitness & Energy Expenditure

QUALITY OF LIFE, CARDIORESPIRATORY FITNESS AND PHYSICAL ACTIVITY LEVELS IN BLACK AFRICAN WOMEN

OVIEDO, G.R.1,2, TAMULEVICIUS, N.3, ONAGBIYE, S.1, PHIDZA, M.1, MADISE, C.1, CZYŻ, S.H.1, MOSS, S.J.1

1 North-West University (Potchefstroom, South Africa), 2 University Ramon Llull (Barcelona, Spain), 3 Barry University (Miami, Florida, USA)

Introduction: Regular physical activity (PA) is associated with health protective effects, higher physical fitness and a better quality of life^{1,2}. It is however unclear whether PA interventions could promote significant changes in Health Related Quality of Life (HRQoL) and whether changes in HRQoL are related to changes in cardiorespiratory fitness (CRF) and physical activity levels (PAL) in black African women from South Africa's low socioeconomic communities. Purpose: To assess the changes in HRQoL, CRF and PAL during a PA intervention in black African women from low socioeconomic communities in South Africa and to investigate the relations between these changes. Methods: A group of black African women ($n=55$; age= 59 ± 11 y) participated in this study and followed an aerobic and strength training program for 12-weeks, 1 h, once a week. Before and after the PA program the SF-8 Health Survey was used to assess the HRQoL. CRF was obtained during a metabolic step test and activity energy expenditure (AEE), total PA (TPA), time spent in sleep/sedentary activities (SST), light PA (LPA) and moderate to vigorous PA (MVPA) were assessed using a combined accelerometry and heart rate monitor (Acti-Heart). Paired t-test was used to compare pre-post results. A multiple linear regression was developed using the changes in HRQoL as response variable, while the explanatory variables were those found to be significant correlated ($p<.20$) with changes in HRQoL using a linear relationship. Results: After the PA intervention significant changes in CRF ($p<0.01$) and HRQoL ($p<0.01$) were observed. VO₂ peak increased from 17.3 ± 4.6 to 23.2 ± 5.5 ml/kg/min ($p<0.01$), while non-significant increases were found for TPA, LPA and MVPA. A non-significant decrease on SST was also found. Change in BMI was associated with change in physical and mental health component ($p<0.05$). Multiple linear regression showed that changes in BMI, AEE, PAL, LPA and MVPA are affecting the change in physical health while change in mental health was related to change in body weight. Discussions: This study showed the beneficial effects of a combined PA intervention in black African women from South Africa's low socioeconomic communities on both CRF and HRQoL. Despite of training once a week increases on PALs and reductions on sedentary behaviours were observed. These changes may lead to prevent cardiovascular diseases and increase HRQoL. References 1. RELATIONSHIP BETWEEN ESTIMATED MAXIMUM OXYGEN INTAKE, PAST SPORTS EXPERIENCE AND PHYSICAL ACTIVITY IN FEMALE UNIVERSITY STUDENTS

NAMBA, H., KUROSAKA, Y., TANAKA, Y., SHIONOYA, Y., MINATO, K.

Nihon University

Introduction Physical inactivity is associated with an increased incidence of obesity, diabetes, cardiovascular disease, osteoporosis, and cancer. Both recent physical activity and past exercise experience are thought to be affect the current fitness level. In this study to clarify the effects of recent physical activity and past sports activities experience on the estimated maximum oxygen intake in female college students. Methods Two hundred eighteen healthy subjects (female, 20.9±1.1 years) participated in this study. The maximum oxygen uptake (50%VO_{2max}) was calculated by running stamina test. An accelerometer (Suziken, Aichi, Japan, life-corder Ex) were attached to an elastic belt and worn at the back of the waist for a week to calculate the average number of steps and the average activity energy expenditure per day. The evaluation of the physical activity self-reported, using the Japanese version of the (GPAQ: Global Physical Activity Questionnaire). Physical activity environment measure, using the Japanese version of the (IPAQ-E International Physical Activity Questionnaire Environmental Module). Exercise self-efficacy was using the five items that made the Marcus et al (1992). From elementary school up to the present, for the sports activities that have been carried out continuously, sports events, the number of practice per week, once of practice time (minutes), and the duration (in years) was described using a questionnaire. Results The average value of the estimated 50%VO_{2max} was 19.5 ± 3.9 ml/kg/min. The third period to continue the exercise experienced groups Elementary school, junior high and high school students of the estimated 50%VO_{2max} (n= 56, 21.2 ± 4.2 ml/kg/min) was significantly higher than None exercise experience group (n=33, 18.4 ± 2.9 ml/kg/min), and one period to the exercise experience group (n=60, 18.6 ± 3.8 ml/kg/min) (p<0.05). The results of multiple regression analysis for the estimated 50%VO_{2max}, sports activities time at the time of junior high school students, sports activities time at the time of high school students, recent sitting time, the number of steps and self-efficacy were significant contribution rate 17.3% ($F = 8.86$, p<0.001). Standard partial regression coefficient was, sports activities time $\beta = 0.223$ (p<0.01) at the time of high school students, exercise self-efficacy $\beta = 0.222$ (p<0.01), and sitting time $\beta = -0.148$ (p<0.05). Discussion Dose-response relationship between the estimated maximum oxygen uptake greater the sports activities becomes higher were observed. Sports activities time at the time of high school students, exercise self-efficacy, following the sitting time have shown that had been affected by the estimated maximum oxygen uptake. Exercise self-efficacy is a recent physical activity from that association was observed, it was considered that it is important to increase the physical activity by environmental improvement such as physical education classes and sports club activities.

A STUDY ON THE RESTING ENERGY EXPENDITURE OF CHINESE ADOLESCENTS IN DIFFERENT PUBERTY STAGE

ZHU, L.

Guangzhou Sport University

Introduction: Resting Energy Expenditure (REE) accounts for the biggest proportion of the total energy consumption. Accurately grasping the information of REE plays an important role in keeping energy balance, maintaining normal body quality, scientifically arranging diet and exercise as well as promoting the growth and development of adolescents. At present, the studies on REE mainly focus on some specific population like adults, metabolic disease patients, critically ill patients or obese children and the main research methods used are actual measurements or estimations based on formula. Although REE conformed through actual measurement can be accurate, it cannot be popularized since the measuring instruments are expensive and the operations are too complicated. REE is calculated on the base of formula or directly estimated through the recommended value of 3.5 ml/kg/min for adults by most scholars. **Methods:** 120 Chinese teenagers aged 11 to 14 years old (62 males, 58 females) voluntarily participated in the experiment. The portable gas analyzer (925g), Cosmed K4b2 (Cosmed, Rome, Italy) can measure the energy consumption in the laboratory and non-laboratory environment, which has been widely employed in the experiment study of energy consumption, including that of the children and adolescents. With a room temperature of 25 ~ 27 °C, all the subjects fasted for more than 2 hours after the meal and wore K4b2 for few minutes to adapt instrument. After being adapted, they were asked to lay down quietly on the mat for a 20-30 min testing. The 16th to 20th minute of the testing data was selected to calculate REE by the Weir formula. The subjects were divided into five stages by means of the Self-administered Pubertal Development Scale (Chinese version), that is, pre-puberty, early puberty, middle puberty, late puberty and post-puberty. **Results:** As to the puberty stage, 33 male subjects were at their middle puberty, accounting for the highest proportion. 20 people (32.3%) were at their early puberty, 8 (12.9%) at pre-puberty and 1 (1.6%) for late puberty. 58 female subjects were at puberty, 41 of whom were at late puberty (70.7%), and 11 (19.0%) at middle puberty, 6 (10.3%) at early puberty. With the continuous development of puberty, REE of the male and female were decreasing. For the male, pre-puberty (7.33±1.62 ml/kg/min, 35.26±7.39 cal/kg/min) > early puberty (6.77±1.22 ml/kg/min, 32.37±5.45 cal/kg/min) > middle puberty (6.12±1.15 ml/kg/min, 29.19±5.44 cal/kg/min) (early puberty VS middle puberty, P<0.05); while for the female, early puberty (6.89±1.44 ml/kg/min, 32.42±6.42 cal/kg/min) > middle puberty (6.57±1.25 ml/kg/min, 31.44±5.83 cal/kg/min) > late puberty (6.18±1.28 ml/kg/min, 29.30±5.97 cal/kg/min) (middle puberty VS early puberty, P>0.05; middle puberty VS late puberty, P>0.05). **Conclusions:** REE of the adolescents with different puberty stage are higher than the 3.5ml/kg/min recommended standard of adults without exception.

ENERGY EXPENDITURES FOR FIVE OUTDOOR FITNESS EQUIPMENTS

HO, C.H., CHOW, H.W., WANG, J.S.

National Cheng Kung University

Outdoor fitness equipment (OFE) has gained popularity in many regions globally. However, the energy expenditures and intensities of operating these equipment are unknown. Thus, this study employed K4b2, a portable device for pulmonary gas exchange measurement, to objectively estimate the energy expenditures and intensities of operating five OFE. Five males and five females were recruited to operate the following OFE: air walker, ski machine, twister, upper limb traction, and rowing machine. The subjects followed the same protocols of operating the machine with random order. The average age of the subjects were 23.7±1.8 and BMI of 23.8±3.8 kg/m². We use METs as indicator for intensity of physical activity, and cal/kg/min for energy expenditure. The average energy expenditure and METs for Air walker is 62.41±10.97 cal/kg/min and 3.55±0.73 METs, Ski machine is 67.19±17.14 cal/kg/min and 3.79±0.99 METs, Twister is 13.02±3.33 cal/kg/min and 2.25±0.62 METs, Upper limb traction is 12.90±3.14 cal/kg/min and 2.24±0.64 METs, Rowing machine is 22.03±4.61 cal/kg/min and 3.72±0.79 METs. These data provides objective assessment of operating OFE in evaluating its goal of achieving public health.

CHANGES IN URINE VOLUME AND SUBJECTIVE MICTURITION DURING WATER EXERCISE IN MEN

WADA, T.1, TAMARI, Y.1, YOSHIDA, N.1, NOSE, Y.2, YOSHIOKA, A.3, ONODERA, S.4

1 Graduate School, Kawasaki University of Medical Welfare, 2 Yasuda women's university, 3 Okayama university, 4 Kawasaki University of Medical Welfare

Purpose: The purpose of this study was to investigate the relationship of in water exercise to urine volume, subjective micturition, oxygen uptake, heart rate, rating of perceived exertion (RPE), blood pressure and rectal temperature during water exercise. Methods: Eight healthy males (age: 22.3 ± 2.1 years, weight: 66.2 ± 10.3 kg, height: 169.5 ± 4.7 cm) subjects volunteered for this study. Each subject signed an informed consent form. The study was conducted in an indoor pool facility at K University, in 2015. This study consisted of two experimental conditions: the land trial and the water trial. The water level was set to the xiphoid. Subjects participated in both conditions on different days. Measurement items were urine volume, subjective micturition, oxygen uptake, heart rate, RPE, blood pressure (SBP: Systolic Blood Pressure / DBP: Diastolic Blood Pressure) and rectal temperature. The water temperature was 30 degrees Celsius. Both conditions began with 30 minutes in a sitting posture on land. Then, for the next 30 minutes, the water trial performed water exercise while the land trial performed exercise. Finally, for the last 30 minutes, both conditions were back on land in a sitting posture. Results: Urine volume after immersion in the water trail was higher than that of land trial ($p<0.05$). Subjective micturition after immersion and recovery at 30 minutes in the water trail were higher than that of land trial ($p<0.05$). No significant differences were found in oxygen uptake, heart rate, RPE, blood pressure and rectal temperature between the water trial and the land trial. Discussion: Venous return increases in water and urine formation rises and then the diuretic effect increases. Previous studies demonstrated that responses to the physical characterizations in water differed from those on land. Compared with in land exercise, the loss of body fluid is increasing by urine in water exercise. These things suggest increased urine volume and subjective micturition. Conclusion: 1) Urine volume and subjective micturition increase through immersion in water. 2) Urine volume increases athletic strength during exercise more in water than on land. COMPARISON OF HEAT RATE AND OXYGEN UPTAKE OF TURNER DURING A PERSON TURNING THE LONG JUMP ROPE DURING THE EXISTENCE AND NON-EXISTENCE OF A JUMPER

YOSHIDA, N.1, WADA, T.1, TAMARI, Y.1, YAMAGUCHI, H.2, ONODERA, S.3

1 Graduate School, Kawasaki University of Medical Welfare, 2 Kibi International University, 3 Kawasaki University of Medical Welfare

Purpose: Elementary schools in Japan undertake physical education classes. However, no reports have investigated the physiological responses of a person turning the long jump rope during long jump rope exercises. The purpose of this study was to clarify the effect on the heart rate and oxygen uptake of the person turning the rope during the existence and non-existence of a jumper. Methods: Subjects were six healthy Japanese males volunteered to participate in this study. Their age, heights and body weights were 22 ± 1 years, 171.7 ± 9.3 cm and 65.8 ± 6.4 kg, respectively (mean \pm SD). All subjects signed informed consent forms prior to participation in this study. Measurement conditions were set for the existence and non-existence of a jumper. The rotational speed of the rope was 90 rpm. The experimental protocol called for sitting on a chair to rest for five minutes followed by three minutes of exercise and five minutes of again sitting on a chair to rest for recovery. The exercise chosen was to turn a jump rope for three minutes under both the aforementioned conditions. The long jump rope used was certified by the NRAJ (National Recreation Association of Japan, length of rope: 10 m). Measurement indexes were heart rate, oxygen uptake, blood pressure and Rating of Perceived Exertion. Results and Discussion: The heart rate of the person turning the rope under the jumper existence condition was significantly higher than that under the jumper not-existence condition at one minute and three minutes after the exercise ($p<0.05$). The oxygen uptake of the person under the former condition was significantly higher than that under latter condition at one minute, two minutes and five minutes after the exercise ($p<0.05$). The Rating of Perceived Exertion of the person under the former condition was significantly higher than that under latter condition at two minutes and three minutes after the exercise ($p<0.05$). Based on these results, the workload of the person turning rope was significantly higher during the existence of a jumper; therefore, turning the rope is a form of anaerobic exercise. These results suggest that the reason for the higher workload was the expanse of the rope. Conclusion: The workload of a person turning the long jump rope was significantly higher during the existence of a jumper.

VALIDITY OF THE MIO FUSE AND ACTIHEART TO MEASURE STEPS AND ENERGY EXPENDITURE IN HEALTHY ADULTS

AVILA, A., CLAES, J., BUYS, R., GOESSLER, K., COOL, H., SEGERS, A., CORNELISSEN, V.

KU Leuven

Introduction. In recent years, the consumer marketplace has been flooded with an array of physical activity monitors. However, to date, little research exists about the validity of these commercially available physical activity monitors. Hence, the purpose of this study was to evaluate the validity of a consumer-based physical activity monitor (MIO Fuse) and a research physical activity monitor (Actiheart) for estimating energy expenditure (EE) and step counts in healthy adults. Methods. Eighteen healthy adults (n=5 males), aged 21 to 36 years (mean BMI $21.7 \text{ kg/m}^2 \pm 3.1$) completed two trials of 50-minutes of standardized structured activity (one familiarization session, one validation session). The participants wore a MIO Fuse on their right wrist, an Actiheart on their chest as well as a portable metabolic system (Oxycon Mobile, Jaeger). Steps were recorded through video-recording. Both sessions started with 10 minutes of rest, followed by walking on a treadmill at low (<3 METs), moderate (4-6 METs) and high intensity (>7 METs) for 10 minutes each, interspersed with set times for rest. Total volume of EE and total estimated-steps were obtained at the end of the session. EE from MIO Fuse and Actiheart were compared with the gold standard, indirect calorimetry. Estimated steps were compared with manual counting of the video recording. Validity was assessed by means of paired T-tests and Bland-Altman plots comparing each device to the criterion method. Results. Total estimated EE from the MIO fuse (211 ± 84 kcal) was not different from the criterion method, indirect calorimetry (206 ± 35 kcal) whereas the estimated number of steps from MIO fuse (3221 ± 31 steps) was statistically different from the video recording (3337 ± 37 | $p=0.01$ |). EE estimation from the Actiheart (157 ± 34 kcal) was significantly lower ($p<0.01$) compared to the criterion method. Bias for EE for MIOfuse was -5.6 kcal (limits: -150.9; 162.2) and 49.4 kcal (limits: no-25.4 to 124.2) for Actiheart. Bias for steps for MIO fuse was -111.0 (-315.65 to 93.52). Conclusion. The present study showed that MIO fuse can accurately measure EE compared to indirect calorimetry but underestimates the number of steps one is taking. In line with previous studies [1], we confirm the low accuracy of the Actiheart to measure EE. Reference [1] Koehler K, et al. European Journal of Sport Science 2013;13(1):31-41

MO-BN13 Neural Responses

INTERMANUAL INTERFERENCE IN MOTOR ADAPTATION

STOCKINGER, C., FRANKE, K., THÜRER, B., STEIN, T.

Karlsruhe Institute of Technology (KIT)

Introduction: Bilateral practice is a profitable method in motor learning which bases on the motor system's capacity to transfer motor memory (Magill, 2007). For instance, adapted motor behavior of arm movements can be transferred from the trained to the untrained arm (Joiner et al., 2013). Contrary, motor memory interference can occur as the retention of a learned motor task A was shown to be degraded when a second task B is learned in-between (Shadmehr & Brashers-Krug, 1997). Yet, it is unclear if both intermanual transfer and interference effects may occur in connection with each other. Thus, the aim of this study was to investigate intermanual interference, i.e., if consecutive learning of two tasks A and B using different arms degrades retention of task A. **Methods:** 36 right-handed subjects (18-30 yrs) performed 2d point-to-point arm reaching movements handling a robotic device (Shadmehr & Brashers-Krug, 1997). Subjects were equally assigned to three groups (C,T1,T2). Following familiarization and baseline measurement of both arms, all groups performed a practice block adapting their right arm movements to a robot-induced force field (task A). Subsequently, test group subjects adapted their left arm movements either to the same force field A (T1) or to force field B of similar structure but reversed direction (B=-A; T2). Control subjects (C) had a break. Finally, all groups were tested for retention of task A with the right arm. To gauge motor performance, error clamp trials were used. This allowed measurement of forces that subjects predictively generated to counteract the expected force field (Joiner et al., 2013). Intermanual interference was assessed using an ANOVA (factors: time [end of practice, retention], group [C,T1,T2]) comparing right hand practice performance and retention of task A. **Results:** Only group T2 showed a significantly degraded retention of task A ($p<.001$, $d=2.15$). The ANOVA revealed a significant time*group interaction ($p<.001$, $pEta^2=.47$). Post-hoc tests indicated significant time*group interactions between T2 and C ($p<.001$, $pEta^2=.44$) as well as between T2 and T1 ($p<.001$, $pEta^2=.48$). There was no significant time*group interaction between C and T1 ($p=.862$, $pEta^2<.01$). **Discussion:** Our results demonstrate intermanual interference effects. Thus, switching arms when learning competing tasks does not prevent interference effects. Contrary, consecutive learning of task A with both arms did not lead to enhanced retention performance compared to control subjects. This might be due to ceiling effects of learning this comparably simple task. Altogether, the findings contribute to an enhanced understanding of motor learning, thus serving as a basis for rehabilitation and sports settings. **References:** Joiner WM, Brayanov JB, Smith MA (2013). MUSCLE FIBER CONDUCTION VELOCITY AND POWER PERFORMANCE: THE INFLUENCE OF FIBER COMPOSITION AND TRAINING BACKGROUND

METHENITIS, S.1, KARANDREAS, N.2, SPENGOS, K.2, ZARAS, N.1, STASINAKI, A.N.1, TSITKANOU, S.1, KARAMPATOS, G.1, BOGDANIS, G.1, TERZIS, G.1

National and Kapodestrian University of Athens,

Introduction: Explosive performance depends upon the rate of force development (RFD) and muscle power, which depend upon a number of neuromuscular variables as well as the type of chronic exercise performed (Cormie et al. 2011). An essential part of the neuromuscular structure is the system which propagates the action potentials along the muscle fibers. However, the velocity of this propagation, muscle fiber conduction velocity (MFCV), has received very little attention as a determinant of muscle power and RFD. Aim of the study was to explore the relationship between MFCV, fiber type composition and power/RFD in participants with different training background. **Methods:** Thirty-eight young males participated (Power analysis: 0.923) according to their training background: sedentary (n=10), endurance (n=9), power (n=10), strength (n=9). They performed countermovement jumps (CMJ) and maximum isometric leg press on force-platforms. Resting MFCV (with intramuscular microelectrodes) and muscle fiber composition (with muscle biopsies) were obtained from vastus lateralis of the dominant leg. Statistics included one-way ANOVA, Pearson's r, partial correlations, stepwise multiple regression and reliability analysis ($p<0.05$). **Results:** The power group had the highest CMJ power, RFD, MFCV, %CSA of type II and IIX fibers, while the strength group performed better than the sedentary and endurance groups in these parameters. Significant correlations were found between MFCV and type II, IIX muscle fibers CSA and %CSA, RFD and CMJ power ($r: -0.358-0.943$; $p<0.001$). These correlations were higher for the power group and lower or non-significant for the sedentary and endurance groups. Partial correlations revealed that the %CSA of IIX muscle fibers dictates the correlation between MFCV, RFD and CMJ performance. Significant and reliable models for the prediction of CSA and %CSA of type II and Ila muscle fibers, based upon MFCV, RFD and CMJ were revealed ($R=0.707-0.935$; $p=0.000$). **Discussion:** The present results suggest that MFCV is related to performance in explosive activities; i.e. higher MFCV leads to higher RFD performance. This relationship depends upon type IIX and II muscle fiber %CSA, as well as the type of chronic exercise training. The combination of MFCV, RFD and CMJ may provide reliable information about the muscle fiber composition. **References:** Cormie et al. (2011). Sports Med, 41(1):17-38. Contact: smetheni@phed.uoa.gr

MODULATION OF SPINAL REFLEX EXCITABILITY IN THE CALF DURING HORIZONTAL JUMP-LANDINGS

THOMPSON, C., SCHABRUN, S., MARSHALL, P.

Western Sydney University

Introduction: Spinal reflex responses are thought to be important for successful performance of landing tasks and stiffness regulation. The pathway of the simple stretch reflex is commonly probed using an electrically induced la-afferent response, or H-reflex. Previous research has examined la-afferent control during drop-jumps however; it is unknown how/if all spinal reflexes functionally contribute to common landing tasks associated with injury in the sporting context. The aim of this study was to analyse la-afferent control during a horizontal jump-landing task. **Method:** Eight healthy individuals participated. H-reflex recruitment curves of the left limb were attained during stance. The ascending portion of the H-reflex recruitment curve was fit with a least-squares sigmoidal function, using Klimstra's model. Stimulus intensity during landing was controlled at 50% of the maximal H-reflex response on the ascending portion of the curve.

H-reflex stimulation was elicited at the short latency response (SLR) of two landing distances: 25 and 50% of maximal broad jump distance. H-reflex amplitude was expressed relative to background EMG (bEMG) at the SLR and M-max [$(H\text{-reflex-bEMG})/M\text{-max, \%}$]. Intra-class correlation coefficient values of stimulation during landing were calculated for 3, 5, 10 and 15 trials. Results Soleus H-reflex amplitude was significantly inhibited during landings compared to stance, and during landings from greater distances. No change in H-reflex amplitude was observed in medial gastrocnemius. bEMG increased during landings from greater distances. Strong reliability of stimulation at H50 during landing was observed in 10 and 15 trials. Discussion Reduced soleus H-reflexes in the 50% condition likely indicates inhibition of Ia-afferents via pre-synaptic mechanisms (descending cortical drive, anticipatory activation of other afferents), or post-synaptic reciprocal inhibition. Based on previous research demonstrating an inverse relationship between bEMG and stiffness, our findings suggest that Ia-afferents may directly contribute to stiffness regulation during landings. Unaltered H-reflex excitability of medial gastrocnemius is most likely attributed to its functional role during the landing task. To better understand how spinal reflexes contribute to successful landing performance, future research should examine the mechanism of Ia-afferent inhibition and its relationship to stiffness regulation in subjects with ankle instability during landing. MODULATION OF CORTICOSPINAL EXCITABILITY FOLLOWING UPHILL VERSUS DOWNHILL LOCOMOTION

GARNIER, Y., LEPERS, R., PAIZIS, C.

INSERM U1093 CAPS - Université Bourgogne Franche-Comté

Introduction Physical activity is widely recommended for health through its cardiovascular, muscular and cognitive improvements (1). It has been shown that neural plasticity in primary motor cortex could be enhanced after a single bout of aerobic exercise (2). The effect of contraction mode (concentric versus eccentric) on corticospinal excitability (CSE) changes has been investigated for single joint movement (3), but not for a global movement such as locomotion. The aim of this study was to investigate the effect of uphill versus downhill running exercise on CSE. We hypothesized that downhill running would lead to greater corticospinal changes compared to uphill running because of a greater amount of muscular afferents inputs. Methods Twelve healthy moderately active volunteers (female = 2, 24.7 ± 4.4 years) participated in three experimental sessions. The first session consisted in an incremental running test (0% slope) to determine maximal heart rate (HRmax) of subjects. Two following sessions consisted in 30-min walking/ running treadmill exercise with a +10% slope or a -10% slope at the same intensity corresponding to 60% HRmax. CSE changes were assessed in an upper limb muscle (abductor pollicis brevis) with motor evoked potential (MEP) by transcranial magnetic stimulation before (PRE), immediately after (POST) and 30 min after exercise (POST30). Results Locomotion velocity was greater during downhill (2.4 m.s⁻¹) than uphill (1.3 m.s⁻¹) exercise despite the same rate of perceived exhaustion at the end of both exercises (11 on Borg scale from 6 to 20). No MEP changes were observed at POST in both conditions. ANOVA showed a main time effect with a significant ($p < 0.05$) MEP amplitude increase at POST30 ($156 \pm 71\%$) compared to PRE values. In addition, a significant ($p < 0.05$) condition effect was shown with greater MEP amplitude increase at POST30 after +10% compared to -10% grade exercise. Discussion Consistently with previous findings, the present data showed that CSE is enhanced for a non-exercise muscle, 30 min after a running exercise but not immediately after (2, 4). Interestingly, uphill locomotion (which implies mostly concentric muscular contractions) induced greater changes in CSE than downhill exercise (which implies mostly eccentric muscular contraction) despite the same exercise intensity. Most predominant mode of contraction during locomotion should be considered in exercise-induced neural plasticity. However, precise mechanisms underlying these changes remain to be elucidated. NEURAL RESPONSES FROM ACUTE RESISTANCE TRAINING DIFFER FROM PREVIOUS SUPER COMPENSATION THEORY.

LATELLA, C.I, HENDY, A.M.I, MAJOR, B.I, TEO, W.I, VANDERWESTHUIZEN, D.3

Deakin University

1 Centre for Physical Activity and Nutrition Research (C-PANI), School of Exercise and Nutrition Sciences, Deakin University 2 Cognitive Neuroscience Unit (CNU), Deakin University 3 Institute of Sport, Exercise and Active Living (ISEAL), Victoria University Introduction Neural adaptations following resistance training are crucial for optimal performance enhancement. The primary aim of this study was to investigate the time-course of neurophysiological adaptations following acute bouts of strength and hypertrophy training for comparison with the conceptual super compensation model (Bompa and Haff 2009). Methods Participants (N=14) completed a randomised, counterbalanced crossover study comparing; control, strength and hypertrophy conditions. The strength condition involved 3 x 5RM leg extensions with 3 min recovery, while the hypertrophy condition involved 3 x 12 RM with 60s recovery. Transcranial magnetic stimulation (TMS) and peripheral nerve stimulation were used to measure excitability of the central and peripheral neural pathways, and maximal voluntary contraction (MVC) to quantify strength changes. Measures were taken pre, immediately post, 10, 20 and 30 mins and 1, 2, 6, 24, 48, 72 and 96 hours following training. Results Significant differences were observed at post, 10, 20, 30 min, 1 and 2 hours for both training groups compared to control group for force, ($p < .05$), maximal compound wave; ($p < .005$), silent period; ($p < .05$) and corticospinal excitability; ($p < .005$). Corticospinal excitability between strength and hypertrophy groups was near significance ($p = .05$), with a large effect ($n^2 = .202$). All measures returned to baseline within 6 hours post training. Discussion To our knowledge this is the first time neurophysiological responses following resistance have been directly measured. Interestingly, strength and hypertrophy training were found to have a similar neurophysiological profile in the acute stages post-training, contradictory to theory that strength training has a larger neural effect and requires longer recovery (Bompa and Haff 2009). Both acute resistance training paradigms caused an increase in MEP amplitude and a subsequent decrease in corticospinal inhibition, rather than neural fatigue as previously proposed (Bompa and Haff 2009). These responses are indicative of neural adaptations observed following longer-term resistance training programs (Kidgell et al. 2010; Weir et al. 2012). References Bompa, TO, Haff, GG (2009). CHANGES IN CORTICOSPINAL EXCITABILITY PRIOR TO RAMP AND BALLISTIC ISOMETRIC CONTRACTIONS

GOUVERNEUR, Y., BAUDRY, S., DUCHATEAU, J.

Université libre de Bruxelles

Introduction Previous work indicates that, in leg muscles, the increase in spinal motor neurone excitability prior to ballistic (BAL) contractions (high rate of force development) was delayed compared with ramp contractions (low rate of force development) (1), and that the excitability of the corticomotoneuronal cells was greater at the onset of BAL than ramp contractions (2). This suggests that corticospinal excitability during the preparatory period of a contraction may be specifically tuned depending on the rate at which force is developed during the subsequent contraction. This study investigated the modulation of corticospinal excitability during the preparatory period of BAL and ramp contractions. **Methods** Twelve young adults performed isometric contractions with the right ankle dorsal flexor muscles. Subjects had to match a template displayed on a monitor with the force of the ankle dorsiflexor muscles. The template represented a ramp (1500-ms duration) or a BAL (150-ms duration) contraction developing the same level of force (force associated with the maximal rate of force development during BAL contraction). Transcranial magnetic stimulation applied over the left motor cortex was used to evoke stimuli at 95% and 120% of the passive motor threshold (MT) in the tibialis anterior, in a 500-ms window preceding the onset of the contractions. Motor evoked potential (MEP) occurrence and amplitude were measured in response to the 95% and 120% MT stimulation, respectively. MEP amplitude was expressed relative to the corresponding Mmax evoked by electrical stimulation of the fibular nerve. Results MEP occurrence in response to 95% MT stimulation increased significantly ($p < 0.05$) between each 100-ms window from 500ms (47% of occurrence) to the onset of the ramp contraction (100% of occurrence) whereas it increased only in the last 100-ms prior to BAL contractions compared with preceding 100-ms windows ($p < 0.05$). Similarly, MEP amplitude in response to 120% MT stimulation increased significantly ($p < 0.05$) between each 100-ms window from 500ms to the onset of the ramp contraction, whereas it increased (+220.1 ± 160.6%) only in the last 200-ms prior to BAL contractions compared with preceding 100-ms windows ($p < 0.05$). **Discussion** Data indicate that the descending drive differs between ramp and BAL contractions, with a delayed and more sudden increase in corticospinal excitability before BAL contractions. This indicates that adjustments within the corticospinal pathway prior to muscle activation differ between ramp and BAL contractions. References 1. Kagamihara et al. (1992) Neurosci Res 14:1-11 2. MUSCLE RECRUITMENT PATTERN BY ELECTROMYOGRAPHY IN RESISTIVE EXERCISE IN DIFFERENT POPULATIONS

SOUZA, G., FIGUEIRA, T., BALDISSERA, V.

Universidade de São Paulo; Universidade Federal de São Carlos

Introduction The surface electromyography (sEMG) is useful for the knowledge of the motor pattern during exercise in healthy individuals and in different conditions; changes of sEMG, can be expressed by the value of the Root Mean Square (RMS), and assist in the diagnosis of changes in neuromuscular degenerative chronic diseases. So the goal was to analyze the participation of lung disease group (PG) with Chronic Obstructive Pulmonary Disease; of heart disease (CG) with heart failure; Type II Diabetics (DG); compared to a healthy group (HG) for resistive exercise of the 'Leg Press' 45°. **Methods** The study included 10 volunteers in each experimental group (PG, CG, DG and HG), aged 50-65 years, who underwent resistance training type 'leg press' instructed to perform a Maximum Voluntary Isometric Contraction (MVIC) for 10 seconds, and after 5 minutes of rest perform repetitions to fatigue in 60% of 1 RM determined in advance. Was recorded during the exercise the electromyographic activity of the muscles Rectus Femoris (RF), Vastus Lateralis (VL), Vastus Medialis (VM) and Biceps Femoris (BF). Was used for the analysis of the electromyographic signal RMS values throughout the movement, and after the signal standard in single percentage for comparison between groups. There were no differences statistics between the groups for age and height, but there was as the body mass. **Results** Regarding the analysis of Surface Electromyographic Signal differences were observed for muscle recruitment during the movement of 'leg press' highlighting that for the PG the most active muscle was the RF (36,5%) followed by the VL (35,8%), VM (20,7%), and BF (17,1%), for CG was BF (30,6%) followed by RF (24,9%), VM (23,5%) and VL (21,1%) for DG was VL (36,5%) followed RF (35,8%), VM (20,7%), and BF (17,1%), while for HG was VL (40,0%), followed by the VM (32,7%), RF (15,9%) and BF (11,4%). **Discussion** There is a different motor recruitment tendency for groups: PG, CG and DG when purchased in HG, since the fatigue process is observed when there is an increase in RMS values, (MC Hugh et al, 2002) so decrease in excitation-contraction coupling, promoting a gradual reduction of contraction force suggesting bankruptcy in synaptic transmission (Barrama et al., 2014) probably by the presence of peripheral neuropathy in patients with chronic diseases degenerative. EFFECTS OF DROPPING HEIGHT AND SURFACE INSTABILITY ON NEUROMUSCULAR PERFORMANCE DURING DROP JUMPS

LESINSKI, M.1, PRIECKE, O.1, BEURSKENS, R.1,2, QUIGLEY, P.J.3, CHAYTOR, C.3, ALCOCK, L.3, REID, J.C.3, HODGSON, D.3, BEHM, D.G.3, GRANACHER, U.1

1: University of Potsdam (Germany); 2: Geriatric Center at the University of Heidelberg (Germany), 3: Memorial University of Newfoundland (Canada)

Introduction It has previously been shown that both, dropping height (Leukel et al., 2008) as well as surface condition (Prieske et al., 2013) have an impact on lower limb muscle activation during stretch-shortening cycle movements such as drop jumps (DJ). However, the combination thereof has not been examined yet. Thus, the purpose of this study was to investigate whether dropping height-induced changes in lower leg muscle activity during DJs are additionally modulated by surface condition. **Methods** Twenty four healthy and physically active participants (23.7 ± 1.8 years) performed DJs on a force plate on stable, unstable, and highly unstable surfaces (i.e., one and two balance pads on top of force plate, respectively) using different dropping heights (i.e., 20 cm, 40 cm, 60 cm). Electromyographic activity of soleus (SOL), gastrocnemius (GM) and tibialis anterior muscles (TA) was recorded and analyzed for time intervals -100 ms to ground contact (i.e., preactivation) and between 30-60 ms after ground contact which corresponds to spinal stretch reflex induced muscle activity (i.e., short latency response (SLR)). Results Repeated measures ANOVA revealed that the increase in dropping height produced significantly higher activities during preactivation in SOL and GM as well as during SLR in SOL, GM, and TA ($p < 0.05$; $1.72 \leq d \leq 3.90$). Further, the increase in surface instability resulted in significantly lower activities during preactivation in GM as well as during SLR in SOL and GM ($p < 0.05$; $1.12 \leq d \leq 3.63$). Moreover, a statistically significant dropping height × surface interaction was observed for SOL during the SLR time interval. Post-hoc tests indicated lower SOL activity with increasing surface instability for moderate (i.e., 40 cm) and high

dropping heights (i.e., 60 cm) only ($p < 0.05$; $1.25 \leq d \leq 2.12$). Discussion Our findings indicate that surface instability modulates activity of selected lower leg muscles in moderate and high, but not in low dropping heights. This result implies that the implementation of unstable surfaces in plyometric training may impair activity of selected muscles at moderate to high dropping heights. THE COMPARISON OF BIOMECHANIC DIFFERENCES IN EMG ACTIVITY OF CALF MUSCLES AT DIFFERENT TYPES OF WALKING

BAVDEK, R., DOLENEC, A., ZDOLŠEK, A., STROJNIK, V.

UL FŠ (Ljubljana, Slovenia)

INTRODUCTION Walking, as the most frequent type of human motion, does not only involve flat terrains, but also uneven surfaces, where there is an occurrence of constant loss and establishment of balance. The calf muscles control the ankle joint function. If they are weak, various injuries to the ankle joint may occur as a result. One of the ways to improve neuro-muscular function of the ankle joint is walking with different variations of the foot position. The purpose of the study was to analyse differences in biomechanics and calf muscle activity during walking on a flat surface, at an inclination of 30° inversion, and at an inclination of 30° inversion at which the subjects tried to keep the lateral part of the foot in the air. METHODS The study included 16 participants walking on a flat surface (Walk), walking at an inclination of 30° to foot inversion (Walk A1), and walking at an inclination of 30° to foot inversion with an ankle eversion (Walk A2). We monitored the changes in biomechanical parameters (walking speed, stride length – SL, contact time – CT) and EMG values at m. TA, m. PL, m. PB, m. SOL, m. GM and m. GL, according to SENIAM recommendations. EMG signal was analysed for the preactivation phase (interval 100ms before the foot touching the surface) and during the contact phase. EMG signals during walking were normalised to corresponding isometric MVC. RESULTS Statistically significant differences in walking were observed in stride lengths (the longest SL at Walk: $130,6 \pm 2,73$ cm) and contact times (longest CT at Walk A: $0,74 \pm 0,17$ s), but not in walking speed. PL was more active at walking at an inclination than on flat surfaces. This was true in the preactivation phase ($p < 0.001$, Walk A2 36,7 %MVC, Walk A 15,9%MVC, and at Walk 8,1 %MVC), as well as in the contact phase ($p < 0.001$, Walk A2 77,2 %MVC, Walk A 57,6 %MVC, Walk 14,2 %MVC). PB was also the most active in the preactivation phase at Walk A2, and the least at Walk A ($p < 0.05$, Walk A2 26,9 %MVC, Walk A 17,3%MVC, and at Walk 9,24 %MVC). However, during the contact phase PB was more active at Walk A than at Walk A2 ($p < 0.001$, Walk A2 45,3 %MVC, Walk A 53,4%MVC, and at Walk 15,1 %MVC). CONCLUSION The study showed, that the length of a stride and the contact time changed during different types of walking, which had also been argued by Voloshina (2013). Our findings showed the increased activity of calf muscles in walking at an inclination than on flat surfaces. This is consistent with the study by Konradsen and Højsgaard (2007). I therefore conclude, that walking at an inclination could be appropriate way of exercise for people with unstable ankles. SOURCES Voloshina, S. A., Kuo, D. A., Daley, A. M. in Ferris, P. D. (2013). THE EFFECT OF A FAILURE- AND SUBMAXIMAL PROTOCOL ON MUSCLE ACTIVATION DURING BLOOD FLOW RESTRICTION RESISTANCE EXERCISE.

STÅLESEN, H., BJØRNSEN, T., BRANKOVIC, R., SUNDNES, J., BERNTSEN, S., PAULSEN, G., WERNBOM, M., RAASTAD, T.

University of Agder

Introduction Blood flow restriction resistance exercise (BFRRE) is a field with growing popularity. Little is known about how effort during BFRRE influences muscle activity. Therefore, the present study aims to compare the effects of a submaximal- (SU) vs. a failure (FA) BFRRE protocol on muscle activity and changes in muscle size and strength. Methods 17 untrained (<2 leg-strength sessions per week, last 6 months) men (18-45 yrs.) completed fourteen BFRRE sessions with unilateral knee-extension divided into two blocks of seven sessions (within five days), separated by a 10-day rest period. Their legs were randomly assigned to either FA or SU protocol. The FA protocol consisted of four sets to voluntary failure while SU-protocol consisted of four sets aiming for 30-, 15-, 15- and 15 repetitions. Both protocols were conducted at 20% of one repetition maximum (IRM), and had 30 seconds rest between sets. The pressure cuff (13.5 cm pressure zone) was inflated to 100 mmHg, and stayed inflated throughout the four sets. Wireless Electromyography (EMG) sensors were positioned on m. vastus lateralis (VL) and m. rectus femoris (RF). Muscle activity (root mean square (RMS) and mean frequency (MNF)) was measured during the first BFRRE session in each training week, and during a maximal voluntary contraction (MVC) test (90° knee angle) prior to each of the BFRRE sessions. All RMS data is normalized to MVC. Muscle thickness was measured using ultrasound imaging. Results In the first session, the Fa group had significantly higher activation of RF during the first set, compared to SU (Fa; $35.5\% \pm 9.5$ RMS normalized to MVC vs. SU $28.3\% \pm 5.9$; $p < 0.01$). Furthermore, there was a tendency to higher activation of VL during the second set in Fa ($43.6\% \pm 12.4$) compared to Su ($36.0\% \pm 9.5$; $p < 0.052$). In the second session, the average activation of all four sets for VL was significantly higher in the Fa group ($43.3\% \pm 8.7$) compared to the SU group ($34.6\% \pm 10.5$; $p = 0.014$). Average MNF in VL of all 4 sets were significantly higher in the SU group in both the first- (SU: 90.7 ± 17.1 Hz vs. FA 75.2 ± 15.1 Hz; $p < 0.007$) and second (SU: 90.5 ± 16.8 Hz vs. FA: 75.7 ± 12.2 Hz; $p < 0.006$) week of BFRRE. Both FA and SU increased their muscle thickness of VL and MVC significantly during the intervention ($p < 0.001$), with no group differences. Discussion We observed a higher activation of RF and a tendency toward higher activation of VL during the FA protocol in the first BFRRE bout. In the first BFRRE bout of the second week, there was a significantly higher activation of VL in FA during the first three sets, compared to the SU protocol. Combined with the downward shift in MNF in the VL FA group, which indicate muscle fatigue; this shows that the failure protocol provides a greater impact on muscle activity. In spite of the higher activation during the FA protocol, we did not find any group differences in changes of strength or muscle thickness. Contact: han-kon.stalesen@gmail.com

RESPONSE OF THE UBIQUITIN-PROTEASOME PATHWAY TO HIGH-FREQUENCY BLOOD FLOW RESTRICTED RESISTANCE EXERCISE

BJØRNSEN, T., PAULSEN, G., WERNBOM, M., AMUNDSEN, R., BERNTSEN, S., RAASTAD, T.

University of Agder

INTRODUCTION High frequency blood flow restricted resistance exercise (BFRRE) has been shown to induce a robust increase in muscle size (1). However, how high-frequency training blocks affects protein degradation systems is still largely unknown. The aim of the present study was to investigate changes in ubiquitin-proteasome pathway markers, muscle size and strength during two weeks of high frequency BFRRE interspersed by 10 days of rest. **METHODS** Thirteen participants (9 men) completed four sets (30 s rest) of unilateral knee-extensions to failure at 20 % of 1 repetition maximum (1RM). Partial blood flow restriction (90–100 mmHg) was induced using a 15 cm wide pressure cuff. Biopsies were obtained from m. vastus lateralis at baseline, four times during and two times post intervention. Muscle tissue was homogenized and fractionated into a cytosolic, membrane, cytoskeletal and nuclear fractions. Muscle ring-finger protein-1 (MURF1), FOXO3a, free ubiquitin (UbF), and ubiquitinated proteins (UbP) were assessed by western blotting. Muscle growth was assessed as changes in muscle fiber area (MFA) using immunohistochemistry and thickness of m. vastus lateralis by ultrasound imaging. Strength was measured as 1RM in knee extension. **RESULTS** Total UbP levels and UbP levels of the cytoskeletal fraction were reduced 1 hour after the first BFR session in both training weeks (total UbP: 1 week -24±17%, p<0.01; 2 week -37±17%, p<0.01; UbP-cytoskeleton: 1 week -24±17%, p<0.01; 2 week -37±17%, p=0.01), compared to baseline. Total UbP levels were reduced also 3 days post exercise (-16±16%; p<0.01). We did not observe any changes in UbF. Cytoskeletal levels of MURF1 increased 1 hour after BFR in both training weeks (1 week 87±62%, p<0.01; 2 week 84 ± 67%, p<0.01), but did not change in other fractions. FOXO3a levels were reduced in the nuclear fraction on the fourth day of BFR (-36±18%, p<0.01) and in the rest week (-25±30%, p=0.01). MFA of type I fibers was significantly increased post intervention (19±20%, p<0.01), and it was significantly higher than in type II fibers where only a tendency towards an increase was observed (12±20%, p=0.051). Muscle thickness of m. vastus lateralis was significantly increased after the intervention (5.1±5.5%, p<0.01) and 1RM in knee extension increased with 6±2% (p<0.01). **DISCUSSION** Two blocks of high frequency BFRRE affected several markers of the ubiquitin-proteasome pathway. Reduced ubiquitination of proteins could indicate either reduced protein breakdown or an increased efficiency of the proteasome system to degrade ubiquitinated proteins. The translocation of MURF1 to the cytoskeleton 1 hour after BFR, may suggest an interaction with titin. Furthermore, reduced FOXO3a levels in the nuclear fraction indicates damped activity during the BFRRE intervention. Interestingly, the muscle growth was more pronounced in type 1 than type 2 fibers. **REFERENCES** 1Nielsen JL et al. J Physiol 590: 4351-4361, 2012 CONTACT thomas.bjornsen@uia.no

DETRENING-INDUCED ALTERATIONS IN ADIPOKINES AND CARDIOMETABOLIC RISK FACTORS AFTER RESISTANCE AND AEROBIC INTERVAL TRAINING IN MEN WITH OBESITY

NIKSERESHT, M.

Islamic Azad University, Ilam Branch, Ilam, Iran

Introduction Evidence supports that exercise training reduces cardiometabolic risk factors especially in obese men (Beavers et al. 2010; Nikseresht et al. 2014b; Nikseresht et al. 2014a), but there is limited research directly comparing different kinds of exercise training. The study aimed to investigate responses of selected markers of adipokines and cardiometabolic risk in obese men during exercise training and detraining. Methods Age- and fitness-matched obese men were allocated to nonlinear resistance training (NRT, n=12, 55-minute of weight training with flexible periodization), aerobic interval training (AIT, n=10, treadmill working with 4 sets 4-minute at 80–90% HRmax) and control (CON, n=11) groups. The training groups performed 3 sessions per week for 12-week followed by a 4-week detraining period. Results Serum retinol-binding protein-4 (RBP-4), interleukin-18 and omentin-1 levels did not significantly change after training compared with CON. No significant changes in RBP-4 occurred in training groups after detraining, but omentin-1 only with AIT (-64%, P=0.002) and IL-18 only with NRT (+53%, P=0.04) worsened significantly. High-density lipoprotein cholesterol (HDL-C) improved significantly after AIT (+10%, P=0.014) compared with CON, and returned to the pre-training values after detraining. Apelin-13 increased significantly after training (AIT=+10%, NRT=+11%; P < 0.02) when compared to baseline levels, but this variable remained significantly above pre-training values after detraining. Discussion It seems that the 2 exercise programs are beneficial overall (e.g. all improvements listed above) but AIT is the only one that had some effects on one (HDL-C) of the lipid profiles, which has been shown to reduce coronary heart diseases risk. Also, detraining in both training programs had comparable results (except for IL-18). Thus, it is suggested that the training programs (especially with NRT) should not be discontinued to prevent future cardiovascular events.

HIGH INTENSITY INTERVAL TRAINING (HIIT) IMPROVES BIOLOGICALLY ACTIVE TESTOSTERONE COMPARED WITH MODERATE CONDITIONING EXERCISE IN LIFELONG SEDENTARY AGING MEN.

HAYES, L.D., SCULTHORPE, N., HERBERT, P., GRACE, F.M.

University of Cumbria

Introduction Testosterone is an important biological hormone which displays a precipitous decline with advancing age. There is a pervasive belief that serum testosterone is favorably affected following short-term (Hayes et al., 2015) and lifetime exercise (Ari et al., 2004) in aging cohorts. The present study examined whether serum testosterone was altered following six weeks of high intensity interval training (HIIT) in a group of 22 lifelong sedentary (SED; 62 ± 2 years) compared with 17 lifetime exercising (LEX; 60 ± 5 years) aging men. We further examined the incidence of androgen deficiency in SED and LEX during the intervention. Methods Total testosterone (TT), sex hormone binding globulin (SHBG), bioavailable testosterone (bio-T), and free testosterone (free-T) were sampled at phase A (baseline), phase B (following low/moderate intensity conditioning exercise), and phase C (following HIIT). Blood was sampled by venepuncture from an antecubital forearm vein and subsequently analysed by electrochemiluminescent immunoassay. Results No difference between groups were observed for TT, SHBG, bio-T, or free-T at phase A, B, or C (P>0.05). TT increased in SED from phase A to B (P=0.007), and remained elevated at phase C compared to phase A (P<0.001). No difference in TT existed between phase B and C (P=0.135). TT in LEX was un-

changed from phase A to B ($P=1.000$), but greater at phase C compared to phase A ($P=0.01$). Free-T in SED remained unchanged from phase A to B ($P=0.102$), and B and C ($P=0.185$). However, free-T was elevated at phase C compared to phase A ($P=0.023$). There was no change in free-T from phase A to B ($P=0.874$), B to C ($P=0.099$), or A to C ($P=0.063$) in LEX. Incidence of androgen deficiency ($TT < 11.3 \text{ nmol L}^{-1}$) was greater in SED than LEX at phase A ($P=0.043$). There was no alteration in androgen status from phase A, to B, to C in either group. Discussion Present data indicate significant changes to TT following moderate intensity exercise in SED, and following HIIT in LEX. However, the biological significance of these changes were largely negated since concomitant increases in SHBG contrived to abrogate change to free-T, leaving only a small increase in free-T following HIIT. In conclusion, moderate conditioning exercise does not alter biologically active free-T concentrations whereas subsequent HIIT improves free-T in lifelong sedentary aging men. As such, SHBG should be measured as an adjunct to TT related research in similar aging cohorts. References Ari Z, Kutlu N, Uyanik BS, Taneli F, Buyukyazi G, Tavli T. CHARACTERISATION OF PHYSICAL ACTIVITY, FUNCTIONAL FITNESS AND BODY COMPOSITION IN YOUNG SURVIVORS OF CHILDHOOD BRAIN CANCER AND CRANIAL RADIOTHERAPY.

LONG, T.M., MARONI, T., CHOONG, C.S., COLE, C.H., WALLMAN, K.E., NAYLOR, L.H.

The University of Western Australia

Recent studies indicate that within 17 years of diagnosis 62% of childhood brain cancer and cranial radiotherapy (CRT) survivors will develop at least one chronic health condition (Oeffinger et al., 2006). Regular exercise improves body composition, musculoskeletal, cardiopulmonary and cardiovascular function, hence decreasing overall likelihood of developing chronic disease. Therefore, this study aimed to characterise physical activity levels, anthropometry, body composition and cardiovascular, musculoskeletal and vascular function in young survivors. Nineteen survivors (9 male, 10 female; age: males 19 ± 3 y, females 20 ± 2 y) were compared with matched controls. Physical activity levels were assessed using Actical accelerometers worn for seven days. Muscular strength, muscular endurance, aerobic capacity (VO_2peak) and anthropometry were assessed according to standard guidelines. Blood pressure and heart rate (HR) measurements were taken at the conclusion of a 20 minute rest period. Body composition was determined using dual x-ray absorptiometry. Cancer survivors were significantly less active than controls, spending an average of 76.8% of the day being sedentary and 15.8 min participating in moderate intensity physical activity. Further, survivors recorded lower muscular strength (lateral pull-downs, $p=0.026$; bicep curls right-arm, $p=0.006$, left-arm, $p=0.012$), muscular endurance (squats, $p=0.007$; sit-ups, $p=0.011$; push-ups, $p=0.008$) and VO_2peak values ($\text{L}\cdot\text{min}^{-1}$, $p=0.002$; $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$, $p=0.009$). Survivors had higher resting HR ($p=0.030$) and were shorter ($p=0.002$) than controls. They also had higher percentages of total body fat ($p=0.013$), android fat ($p=0.003$) and gynoid fat ($p=0.023$), and experienced deficits in total lean body mass ($p=0.006$), total bone mineral content ($p=0.000$) and total bone mineral density ($p=0.007$). This study demonstrates that survivors of childhood brain cancer and CRT engage in less physical activity, have altered body composition and experience muscular weakness and aerobic deficiency. This is important as long-term inactivity not only exacerbates physical performance limitations but can induce the development of risk-factors that predispose survivors to chronic health conditions (Florin et al., 2007). Florin, T. A. et al., 2007. Cancer Epidemiology Biomarkers & Prevention, 16, 1356-63. Oeffinger, K. C. et al., 2006. The New England Journal of Medicine, 355, 1572-82.

VERIFICATION OF THE LACTATE-TURN-POINT DETERMINATION BY MEANS OF CONSTANT-LOAD BICEPS CURL EXERCISE

SPENDIER, F., MÜLLER, A., KORINEK, M., TSCHAKERT, G., GRÖSCHL, W., HOFMANN, P.

University of Graz

Introduction Resistance training is regulated by %1-repetition max (1RM) weight, number of reps and sets. In endurance sports, turn points (TPs) are a "gold standard" for exercise prescription (Tschakert & Hofmann, 2013) also described for resistance exercise (Maté-Muñoz et al., 2015). Aim of our study was to determine the first (LTP1) and the second (LTP2) lactate TPs during an incremental resistance exercise test (IET) and to verify these TPs by constant-load tests (CLT). Methods 12 subjects (age: 24.8 ± 3.1 yrs.; height: 181.4 ± 7.3 ; body mass: 76.0 ± 8.1 kg) performed a one-arm biceps curl IET after a 1RM test to calculate the step rate for the IET (1RM/45). After warm-up (3 min) workload was increased every min (30 reps/min) until maximum. LTP1 and LTP2 were determined by linear regression break point analysis. To verify the TPs CLTs were performed 5% Pmax IET below and above each TP. These tests were performed in the same way than the IET until the target load was reached and then kept constant for 30 min. Heart rate (HR), blood lactate concentration (La) and gas exchange variables were measured. Results Peak load in the IET was 5.3 ± 0.9 kg (Lamax: 2.20 ± 0.40 mmol/l; HRmax: 135 ± 15 b/min; VO_2max : 1.15 ± 0.30 l/min). LTP1 was detected at 1.9 ± 0.6 kg (La: 0.86 ± 0.36 mmol/l; HR 90 ± 13 b/min; VO_2 : 0.50 ± 0.05 l/min) and LTP2 at 3.8 ± 0.7 kg (La: 1.38 ± 0.37 mmol/l; 106 ± 10 b/min; VO_2 : 0.62 ± 0.11 l/min). CLE showed La steady state in all tests except CLE above LTP2. Delta-La (rest-30min) were found at -0.17 ± 0.27 mmol/l below LTP1, at 0.13 ± 0.41 mmol/l above LTP1, at 0.79 ± 0.72 mmol/l below LTP2, and 1.36 ± 0.63 mmol/l above LTP2 with an early termination of the test at 16.5 ± 9.1 min. Discussion It was possible to determine LTP1 and LTP2 during a one-arm biceps curl IET similar to cycle ergometer IET (Tschakert & Hofmann, 2013). The CLE around the TPs validated the three phase concept for cardiorespiratory and metabolic variables and a steady state was found in all tests except above LTP2. Subjects had to stop exercise because of muscular fatigue and/or non steady state La. These results showed that the three-phase model (Tschakert & Hofmann, 2013) is also applicable for resistance training. References Maté-Muñoz, J. L., Domínguez, R., Barba, M., Monroy, A. EFFECTS OF RESISTANCE TRAINING ALONE OR COMBINED WITH NUTRITIONAL SUPPLEMENTATION AND COGNITIVE TRAINING ON CHRONIC LOW-GRADE INFLAMMATION OF OLDER ADULTS

WACHTER, D., HOFMANN, M., SCHÖBER-HALPER, B., OESEN, S., FRANZKE, B., STRASSER, E.M., WAGNER, K.H., WESSNER, B.

University of Vienna

Introduction Ageing, inactivity and obesity are associated with chronic low-grade inflammation contributing to a variety of lifestyle-related diseases. While it is generally accepted that aerobic exercise exerts beneficial effects on several aspects of immune function even in older

adults, the effect of resistance training remains unclear [1,2]. The aim of this study was to investigate whether a long-lasting progressive resistance training (6 months) with or without nutritional supplementation (proteins and vitamins) would influence circulating C-reactive protein (hs-CRP), interleukin-6 (IL6) and the anti-inflammatory interleukin-1 receptor antagonist (IL1ra). Methods Older adults (n= 117, 14 men and 103 women, age: 65.0 - 97.4 years, BMI: 18.1 – 50.0 kg/m²) were randomly assigned to one of the 3 intervention groups: resistance training (RT), RT plus nutritional supplement (FortiFit, Nutricia) (RTS) or cognitive training (CT) [3]. All three groups met twice a week for 6 months. Physical performance (6-minute walk test (6MWT), handgrip strength and chair stand test) as well as biochemical analyses were performed at baseline and after 3 and 6 months. Circulating hs-CRP, IL6 and IL1ra were measured by high sensitive ELISA kits. Statistical differences between groups were detected by Kruskal-Wallis test, whereas time effects were assessed by Friedman test. Results While similar improvements in RT and RTS were observed for chair stand test (RT: p=0.001; RTS: p=0.003) and 6MWT (RT: p=0.021; RTS: p= 0.015, we did not observe any alterations in hs-CRP, IL6 or IL1ra (p>0.05). However, chair stand performance at baseline correlated negatively with hs-CRP ($\rho = -0.201$, p=0.030) and IL6 ($\rho = -0.203$, p=0.043), while 6MWT was associated with IL1ra ($\rho = -0.230$, p=0.021). The percentage body fat ($\rho = 0.273$, p=0.006) and negatively with hs-CRP ($\rho = 0.273$, p=0.006) and negatively with IL1ra ($\rho = -0.246$, p=0.016). Discussion Results from this study suggest that RT does not affect the chronic inflammatory state of older adults, although a better physical fitness is associated with lower levels of hs-CRP and IL6. As body fat, and especially visceral fat, is an important source of pro-inflammatory mediators [4], it needs to be proven whether RT would influence chronic inflammation when combined with a weight management programme. EFFECT OF PRECONDITIONING EXERCISE ON MUSCLE BEHAVIOUR DURING MAXIMAL ELBOW FLEXOR ECCENTRIC CONTRACTIONS

HO, C.C.1, TSENG, K.W.2, NOSAKA, K.3, CHEN, T.C.1

1:NTNU (Taiwan), 2:UT (Taiwan), 3:ECU (Australia)

Introduction Performing 30 low-intensity eccentric contractions (1) or two maximal voluntary isometric contractions at a long muscle length (2) attenuates changes in indirect markers of muscle damage after 30 maximal eccentric contractions of the elbow flexors. However, the mechanisms underpinning this preconditioning effect are unknown. A recent study (3) showed that changes in the magnitude of biceps brachii distal myotendinous junction displacement (MTJd) over sets were smaller in the second than the first maximal eccentric exercise of the elbow flexors. The present study investigated the hypothesis that performing 30 low-intensity eccentric contractions or two maximal isometric contractions would change MTJd during maximal eccentric contractions. Methods Healthy untrained young men were randomly placed (n=13/group) to a control group that performed 5 sets of 6 maximal elbow flexor eccentric contractions (MaxEC) with the non-dominant arm, or one of two preconditioning groups that performed either 30 low-intensity (10% of maximal voluntary isometric contraction strength) eccentric contractions (10%EC) or 2 maximal voluntary isometric contractions at 20 degree elbow flexion (2MVIC) 2 days before MaxEC with the non-dominant arm. MTJd was assessed by B-mode ultrasound longitudinal images recorded during MaxEC, and its changes over sets were compared among the groups. Changes in several indirect muscle damage markers (e.g. maximal voluntary concentric contraction torque (MVC-CON), range of motion (ROM), muscle soreness) before, immediately after, and 1-5 days after eccentric exercise were also compared among the groups by a mixed-design two-way ANOVA. Results MTJd changes in the first MaxEC set were similar among the groups (6.18 ± 0.20 mm), but the changes over sets were smaller ($P<0.05$) for the 10%EC (e.g. 5th set: 7.18 ± 0.60 mm) and 2MVIC (6.90 ± 0.60 mm) groups than the control group (7.70 ± 0.80 mm). The 10%EC and 2MVIC groups showed smaller ($P<0.05$) changes in all muscle damage markers after MaxEC than the control group, without a significant difference in the changes between the 10%EC and 2MVIC groups. Discussion These results confirmed the previous studies (1,2) showing that 10%EC and 2MVIC performed 2 days prior to MaxEC attenuated muscle damage after MaxEC. The magnitude of muscle length changes over sets in MaxEC was reduced when 10%EC and 2MVIC were performed prior to MaxEC, supporting the hypothesis. It appears that the smaller MTJd over sets during MaxEC is a possible mechanism underpinning the protective effect conferred by the precondition exercises. References 1)Chen et al. EFFECTS OF ELECTROSTIMULATION WITH BLOOD FLOW RESTRICTION ON MUSCLE CONTRACTILE PROPERTIES

DOMÍNGUEZ-CASTELLS, R., LAZA-CAGIGAS, R., MONTALVO-ZENARRUZABEITIA, Z., CALLE-HERRERO, J.

Spanish Agency for Health Protection in Sports (Spain)

Introduction Neuromuscular electrostimulation (NMES) is well known for its potential as a strength training tool for healthy subjects and athletes among a wide range of applications. Some studies have recently used the NMES combined with blood flow restriction (BFR) to induce muscle hypertrophy and strength gain. However, the effects of this technique on muscle contractile properties are unknown. The purpose of this study was to investigate the effects of NMES combined with BFR on muscle contractile properties and peripheral fatigue assessed by tensiomyography (TMG). Methods The motor point of the vastus medialis was determined in nine physically active men (age: 23.0 ± 3.8 years, height: 178.1 ± 5.8 cm, body mass: 71.9 ± 3.9 kg) and electrodes were placed on both legs to apply a NMES protocol and to conduct TMG measurements. One leg was randomly selected to apply BFR combined with the NMES protocol, while the other leg had free blood circulation. A cuff was placed on the BFR leg at groin level and inflated to 300 mmHg for 5 minutes to reduce muscle oxygen considerably before NMES was applied. Immediately after 5 minutes, NMES was concurrently applied on both legs. The protocol consisted of 5 cycles of 72 seconds (1s on, 1s off), with a total of 36 contractions per cycle. Frequency was established at 40Hz and intensity was set at individual tolerable limit. Rest between cycles was 40 seconds. Measurements of TMG (Dm: maximum displacement; Td: delay time; Tc: contraction time) were taken before the NMES protocol (PRE), 30 s after each NMES cycle (NMESn). A muscle oxygen saturation monitor was placed on the vastus lateralis. Results Muscle oxygen saturation (OXY) stayed below 5% during the whole NMES protocol. Dm decreased gradually along the NMES protocol. It was significantly lower in NMES2,3,4,5 compared to PRE (4.43 ± 1.41 mm, 4.19 ± 1.81 mm, 4.08 ± 1.94 mm, 3.98 ± 1.83 mm, respectively vs 7.56 ± 1.65 mm, $p < 0.05$). On the contrary, Td increased with the NMES protocol. It was significantly higher in NMES2,3,4,5 compared to PRE (30.55 ± 6.22 ms, 34.42 ± 6.22 ms, 34.87 ± 9.41 ms, 35.68 ± 10.27 ms, respectively vs 23.94 ± 1.86 ms, $p < 0.05$). Tc did not change significantly. Conclusion The decrease in Dm after the NMES protocol suggests an inability to activate muscle fibers. Besides, the increase in Td suggests lower muscle excitability. Both facts together are related to worse muscular contraction capabilities. Therefore, we can conclude that the combination of a NMES protocol combined with BFR induces higher peripheral fatigue and further impairment of the muscle contraction capabilities. THE EFFECT OF THE ORDER OF CONCURRENT TRAINING ON MUSCLE HYPERSTROPHY

TAKANAGA, S., THORU, T.

University of Tsukuba

Introduction In many sports, athletes have to show maximum performance during competitions. Therefore, they want to improve energy supply by many ways of energy metabolic mechanism. Much has been studied on the differences in training methods whether those can improve endurance, muscular strength together. Aerobic training increases slow-twitch muscle fiber which causes the body adaptation suitable for the movement to be long-lasting. Resistance training which causes muscle hypertrophy and increase strength. Therefore, there is a conflict of body adaptation caused by differences in the respective training. Concurrent training is one of the training methods to be performed in combination with endurance and resistance training. In this study, we analyzed the change in signals for muscle hypertrophy by the difference of the order of concurrent training. Methods 7 weeks of age male DDY mice were divided into 3 groups: control (con), endurance before resistance (EE-RE), endurance after resistance (RE-EE). After 3-week training, mice were sacrificed and plantaris muscles were dissected out quickly from each mouse for subsequent analyses. EE-protocol The mice were familiarized with running on a rodent treadmill at 10–20 m/min for 3 days prior to the experiment. Subsequently, they were placed on a flat treadmill and made to run for 30 min at a speed of 20m/min. RE-protocol The mice were positioned with their foot on a footplate (the ankle joint angle was positioned at 90°) in the prone posture. The triceps calf muscle was stimulated percutaneously with electrodes which were connected to an electric stimulator and isolator. The gastrocnemius muscle was isometrically exercised (3-s stimulation 10 contractions, with a 7-s interval between contractions, for 5 sets with 3-min inter set intervals). The voltage (30 V) and stimulation frequency (100 Hz) were adjusted to produce maximal isometric tension. Results After 3-week training, there were no significant difference in body weight and gastrocnemius wet weight between those of EE-RE, RE-EE and control groups. Using Western blot, we analyzed the change in signal molecules. P70S6K and S6 phosphorylation were significantly increased in RE-EE group compared with control group. S6 phosphorylation of EE-RE group also increased, but not significant. We could not find the difference due to the order of concurrent training was not observed. Discussion We found concurrent training promoted muscle protein synthesis. Concurrent training, especially protocol with resistance training before endurance training, it was suggested to promote hypertrophy more efficiently. INFLUENCE OF A STRENGTH TRAINING PROGRAMME ON BALANCE CONTROL IN OLDER ADULTS

STRAGIER, S.1,2, POORTMANS, J.1, CARPENTIER, A.1,2, DUCHATEAU, J.2, BAUDRY, S.2

Université Libre de Bruxelles

Introduction Maximal force of the ankle plantar flexor (PF) muscles plays a key role in postural control (1). The decrease in maximal PF force with ageing should therefore contribute to alter balance steadiness in this age group (4). However, some studies reported only modest effects of a strength training programme on bipedal balance control in older adults (3). This may reflect the fact that bipedal upright stance does not require a high level of PF force (4). The purpose of this work was to study the effect of a 6-month strength training programme on the steadiness of upright standing in bipedal and one leg stance in older adults. Methods Forty-one older adults (>60 yrs) completed the study. One group (n=21) performed strength training (2 sessions/week) of lower limb muscles for 24 weeks and the other 20 subjects composed a control group. The maximal torque of PF and dorsiflexors (DF) was assessed during maximal voluntary contractions (MVC) performed in isometric condition. The mean centre of pressure (CoP) velocity, forward-backward maximal amplitude (F-Bmax), and standard deviation (F-Bsd) of CoP were analysed while subjects stood upright on a force platform on one or two legs. The surface electromyogramme (EMG) of different leg muscles were also recorded. Results The MVC torque produced by the PF and DF muscles increased ($p<0.05$) after the training programme by 32 % and 17%, respectively. The F-Bmax and F-Bsd in the sagittal plan decreased during one leg stance (-11% and -7%, respectively; $p<0.05$), whereas no change was observed during bipedal stance. The PF EMG decreased ($p<0.05$) after training during one leg (-16%) and bipedal (-7%) upright standing. The decrease in CoP mean velocity (-11%) was correlated with the increase in MVC torque of the DF ($r^2=0.47$; $p<0.001$) and the decrease in tibialis anterior EMG ($r^2=0.22$; $p<0.05$) during one leg stance. Discussion In agreement with our hypothesis, strength training of lower limb muscles increased upright standing steadiness only when performed on one leg. Furthermore, the relation between the decrease in tibialis anterior EMG and the CoP mean velocity suggests that reducing the activity of ankle DF muscles may help controlling upright standing, by improving its role in providing relevant proprioceptive information (2). These results indicate that strength training should be included in fall prevention programmes to improve balance control in more demanding physically daily activities. References 1.Billot et al. Mini-Orals**MO-BN02 Cycling****ESTIMATION OF THE TRUNK MUSCLE FORCE IN BICYCLE PEDALING USING AN INVERSE DYNAMICS COMPUTATION.**

KITAWAKI, T., TOKUYASU, T., OKA, H.

Kansai Medical University

Introduction: In order to evaluate bicycle pedaling skills, it is important to describe the use of the trunk muscles of the subject, such as iliacus muscle and major psoas muscle (hip flexors) which is related to the role to lift the lower extremities. We have developed a device that can easily and accurately measure crank angular velocity (1); however, few studies have shown a relationship between pedaling skills (or pedaling effectiveness) and the force of the trunk muscles during the bicycle pedaling. Accordingly, estimation of trunk muscle force during the pedaling may be beneficial for pedaling skills training. In this study, we therefore intended to estimate the trunk muscle force using actually measured value of the pedaling force for inverse dynamics computations in bicycle pedaling. **Methods:** We use reacting force of the bicycle (pedal force, saddle force and handle force), and pedaling action (pedaling posture, crank angle), obtained from a measurement system. And surface muscle force using electromyogram (EMG) was used in order to evaluate the accuracy of the computations. A participant was given the pedaling load (100W and 250W) by bicycle trainer, with specified cadence (60rpm, 90rpm).

Using crank angle obtained from the measurement system, the reacting forces of the bicycle and EMG signals were averaged at crank angle (every 5 degree) at each pedaling condition. Results & discussions: Using the averaged value of pedal force and pedaling action data vary with crank angle, inverse dynamics calculations have been performed by commercially available software (AnyBody). The saddle and handle force was not used for calculations, because it was difficult to take in. Since the freedom of pedaling motion remains, it is necessary to define the constraint condition of pedaling motion in the calculation. Moreover, calculation result was sometimes become unstable. As a result, calculated muscle activity changes can be compared with measured EMG values. However, these values did not match so well. Acknowledgments: This research was supported in part by JSPS KAKENHI Grant-in-Aid for Scientific Research (C), 25350763. EFFECTS OF INSPIRATORY MUSCLE TRAINING ON VENTILATORY EFFICIENCY AND CYCLING PERFORMANCE

SALAZAR-MARTÍNEZ, E., BURTSCHER, M., PÉREZ-DEL RÍO, A., NARANJO ORELLANA, J., SANTALLA, A.

University Pablo Olavide, Sevilla

Introduction It is well known that inspiratory muscle training (IMT) can improve performance in endurance athletes. However, the mechanisms responsible for these performance improvements remain unclear. Ventilatory efficiency might be a factor potentially explaining these improvements (Sheel, 2002). The aim of this study was to investigate the influence of IMT on ventilatory efficiency and cycling performance. Methods Eight male and eight female subjects (VO_{2max}; 47.07± 5.64 ml·kg⁻¹·min⁻¹) were randomly assigned to the inspiratory muscles training group, (IMTG, n=9) or the control group (CG, n=9). Both groups performed an incremental cycle test to exhaustion with respiratory gas analysis, a peak inspiratory pressure test (Pimax) and performed a 10-min time trial (TT) before and after a 6-week lasting inspiratory muscle training period. The IMTG performed 60 IMT sessions, consisting of 30 breathing repetitions with a PowerBreathe® device at 50%Pimax, 2 times per day, 5 days per week. The control group performed the same breathing training without applying any resistance. The Pimax and training load was checked each week. Results Pimax, TT and peak power output (PPO) improved significantly within the IMTG ($p<0.05$). The VE/VCO₂ slope, ventilatory equivalent of CO₂ (VE/VCO₂) and VO_{2max} remained unchanged after the 6-week training period in both groups. Interaction effect was found between groups (group x time) in Pimax and TT after IMT. Significant correlations were found between Pimax, TT and PPO in both groups ($r=0.869$, $p<0.001$; $r=0.873$, $p<0.001$). Discussion Results are in accordance with previous work which demonstrated that IMT improved time trial cycling performance (Romer, McConnell, & Jones, 2002). However, our findings do not confirm the hypothesis that these improvements would be related to changes in ventilatory efficiency. Apparently the IMT is not able to modify the control of breathing and thus promoting more efficient breathing patterns. The sensitivity of the peripheral chemoreceptors seems not to be modified by the improvements in breathing muscle strength after IMT. Unchanged VE/VCO₂ values at the second ventilatory threshold indicate that the mechanical ventilatory efficiency was unaffected after IMT. Therefore, it is concluded that improvements in cycling time trial performance are not related to changes in ventilatory efficiency. However, our results suggested that the improvement in cycling performance might be related to improvements in breathing muscle strength. References Romer, L. M., McConnell, A. K., & Jones, D. A. CEREBRAL OXYGENATION DURING GRADED CYCLING TO EXHAUSTION IN WOMEN USING ORAL CONTRACEPTIVES

QUINN, K., MINAHAN, C.

Griffith University GC, Aus

Introduction Reduced maximal oxygen uptake (VO_{2max}) has been reported in women using oral contraception (WomenOC) when compared to normally-menstruating women (WomenNM; Casazza et al. 2002; Joyce et al. 2013). A reduction in cerebral oxygenation during severe-intensity exercise has been associated with exercise exhaustion (Oussaidene et al. 2013) and may pose as a potential mechanism for the reduced VO_{2max} observed in WomenOC. The aim of the present study was to investigate the effects of long-term use of oral contraceptives on frontal cortex oxygenation (i.e., cerebral oxygenation) during graded cycling to exhaustion in recreationally-active women. Methods Eight WomenOC and eight WomenNM performed a graded-cycling test to exhaustion to determine VO_{2max} (VO_{2max} test) and lactate threshold 1 and 2 (LT1 and LT2). Left pre-frontal cortex oxygenation was monitored by near-infrared spectroscopy (NIRS) through concentration changes in oxy-, deoxy-, and total haemoglobin (HbO₂, HHb and tHb, respectively), along with an index of pre-frontal tissue saturation (TSI). Pulmonary gas exchange was measured throughout the VO_{2max} test using open circuit spirometry. Results VO_{2max} was not different between the two groups (WomenNM: 2.67(0.56) L/min; WomenOC: 2.69(0.47) L/min; $p = 0.83$). HbO₂ was lower in WomenOC at rest; yet, the rate and magnitude of increase in HbO₂ from the onset of exercise to LT1 were greater in WomenOC compared to WomenNM. At a work rate equal to that achieved at LT2, TSI declined for both groups, and all measures of cerebral oxygenation were similar between groups at exhaustion ($p>0.05$). Discussion When matched for VO_{2max}, we observed different patterns of increase in cerebral oxygenation during graded cycling to exhaustion in WomenOC compared to WomenNM. However, there was no evidence of impaired cerebral oxygenation during severe-intensity exercise in either group. The suppression of 17 β -estradiol and progesterone, as well as the elevation of ethinyl-estradiol and progestin associated with oral contraceptive use does not appear to affect cerebral hemodynamics during graded cycling. HOW ACCESS TO AN E-BIKE AFFECTS AMOUNT AND PATTERNS OF BICYCLE USE IN INACTIVE NORWEGIAN ADULTS: A PILOT STUDY.

MALNES, L.I., LOBBEN, S.E.3, BERE, E.1, MILDESTVEDT, T.2, TJELTA, L.I.3, KRISTOFFERSEN, M.4, BERNTSEN, S.1

1:University of Agder, Norway. 2:University of Bergen, Norway. 3:University of Stavanger, Norway. 4:Bergen University College, Norway.

Introduction Electric assisted bicycles (E-bikes) have become increasingly popular worldwide during the last decade. Bicycle use with an E-bike (E-biking) may be categorized as a physical activity of moderate intensity. Few studies have examined whether access to an E-bike influences bicycle use and fitness. The aims of the present study were to assess the effect of an eight-month intervention with access to an E-bike on (1) the amount of E-biking and (2) assess whether E-biking is associated with changes in maximal oxygen uptake (VO_{2 max}),

among inactive adults. Methods Twenty-five inactive Norwegian adults (33 – 57 years of age, 72 % women), who did not cycle or walk to work, were recruited through convenience sampling, in September 2014. Participants were given an E-bike for eight (N = 23) or three (N = 2) months. Prior transportation habits and demographic characteristics were reported with a questionnaire. Bicycle use was measured with GPS bicycle computer (Garmin Edge 500, Southampton, UK). The participants' VO₂ max was directly measured, before and after the intervention, using a modified Balke protocol while walking/running on a treadmill until exhaustion. Results At baseline, a large proportion (94 – 100 %) of the participants reported using motorized transport (car or bus) when shopping and during leisure time. During the intervention, participants spent on average 107 ± 62 minutes cycling per week covering 37.6 ± 24 kilometres per week. Distance cycled were significantly (P = 0.035) higher in the fall (47.4 km/week) than in the spring (32.1 km/week). Participants cycled significantly (P = <0.001) more on weekdays (7.1 km/day) compared to weekend days (0.9 km/day). A significant improvement in VO₂ max (7.7 %, P = <0.001) from baseline (34.1 ml/kg/min) to post test (36.4 ml/kg/min) were associated with cycling distance ($r = 0.49$, P = 0.042). When stratified by cardiopulmonary fitness status at baseline (defined as below or above predicted VO₂ max value), the group with lower fitness had a considerable increase in VO₂ max (9.6 %, P = <0.001) associated with cycling distance ($r = 0.64$, P = 0.014), while no changes were observed in the group with higher fitness (1.5 %, P = 0.626). Discussion Access to an E-bike for eight months resulted in weekly 37.6 km of cycling and average 7.7 % improvements in cardiopulmonary fitness. Cycled distance was positively associated with improvements in cardiopulmonary fitness. E-bikes may contribute to mobilize inactive individuals to initiate transport-related physical activity. IMPORTANCE OF SLOW COMPONENTS OF HR AND VO₂ KINETICS DURING SUBMAXIMAL CYCLING ON EXERCISE INTENSITY PRESCRIPTION

ZUCCARELLI, L.1,2, RASICA, L.1,2, MARZORATI, M.1, PORCELLI, S.1, GRASSI, B.1,3

1Institute of Bioimaging and Molecular Physiology, National Research Council 2Department of Biomedical Science for health, University of Milan 3Department of Medical and Biological Sciences, Udine

Introduction Aerobic activities prescription is often based on a linear relationship among pulmonary oxygen consumption (VO₂) and heart rate (HR) vs. power output. However, it is known that during constant work-rate exercise (CWR) above the gas exchange threshold (GET) the linear relationship between VO₂ and power output is lost and a "slow component" of VO₂ is present [Jones et al. 2011]. Something similar seems to occur also for HR [Orizio et al. 1998]. The aim of the present study was to test the hypothesis that the slow component of HR kinetics occurs at lower CWR and is more pronounced than the slow component of VO₂ kinetics. Methods Nine male (age= 23 ± 2 yr, height = 181 ± 5 cm, mass= 76.5 ± 7.4 kg; VO_{2peak}= 52.9 ± 6.2 ml*kg⁻¹*min⁻¹) well trained subjects performed on a cycle ergometer an incremental test to voluntary exhaustion (to determine VO_{2peak} and GET) and 4 CWR in a randomized order: 1) moderate CWR (MOD), at 40 % of VO₂ peak (MOD), 2) heavy CWR (HEAVY), at 25% of the difference between GET and VO₂ peak (25% Δ), 3) severe CWR (SEVERE) at 75% Δ; 4) work rate was continuously adjusted to maintain a HR constant at a value corresponding to that determined at GET (HRGET). Breath-by-breath VO₂, heart rate (HR) and cardiac output (CO) were recorded during all tests and blood lactate concentration ([La-]) was measured at rest and after exercise. Results In MOD: end-exercise VO₂ was 2.036 ± 0.075 L*min⁻¹ and VO₂ Kinetics followed a monoexponential function; HR reached 135 ± 16 beats*min⁻¹ and its kinetics was described by a biexponential model, with the slow component amplitude corresponding to 27.4 ± 5.6% of the total response. During HEAVY a biexponential model was described for both VO₂ and HR kinetics, reaching 4.145 ± 0.542 L*min⁻¹ with a slow component of 26.4 ± 9.2 % and 187 ± 5.6 beats*min⁻¹ with a slow component of 28 ± 14 %, respectively. In SEVERE no steady state was achieved, and VO₂ and HR continued to rise with time (VO₂= 4.225 ± 0.694 and HR= 183 ± 6 beats*min⁻¹) with a slow component amplitude of 22 ± 11.9 % and 24.5 ± 6.7 %, respectively. During the HRGET test, both work rate (190 ± 21.8 W) and VO₂ (3.050 ± 0.220 L*min⁻¹) had to decrease in order to maintain a constant HR. Conclusion As hypothesized, the slow component of HR kinetics occurs at lower work rates and is more pronounced than the slow component of VO₂ kinetics (in order to maintain HR constant at its GET value, both work rate and VO₂ have to decrease). This has important implications in terms of submaximal exercise intensity prescription. EFFECTS OF HIGH INTENSITY INTERVAL CYCLING PERFORMED AFTER RESISTANCE TRAINING ON MUSCLE STRENGTH AND HYPERTROPHY

TSITKANOU, S.1, SPENGOS, K.2, STASINAKI, A.N.1, ZARAS, N.1, BOGDANIS, G.1, PAPADIMAS, G.2, TERZIS, G.1

1: National and Kapodistrian University of Athens, 2:University of Athens Medical School

Introduction Human skeletal muscle has a remarkable ability to adapt to external stimuli such as exercise training. Different exercise modes induce specific muscle adaptations which may however oppose one another. For instance, when low intensity-long duration aerobic exercise is combined with resistance exercise muscle hypertrophy is impeded (Wilson et al., 2012). Aim of the study was to investigate whether high-intensity interval cycling performed immediately after resistance training would inhibit muscle strength increase and hypertrophy anticipated with resistance training per se. Methods Twenty-two moderately-trained young men (21.8 ± 0.6 years, body height 177.4 ± 1.5 cm, body mass 74.2 ± 2.1 kg) were assigned into either resistance training per se (RE; N=11; 4 set × 6 RM in leg press and half-squat) or resistance training plus high-intensity interval cycling (REC; N=11; 4 set × 6 RM in leg press and half-squat plus 10 set × 60sec in cycle ergometer, 90–95% HRmax, rest 60sec). Lower body muscle strength, rate of force development (RFD), quadriceps cross sectional area (CSA) and vastus lateralis architecture (with ultrasonography), muscle fiber type composition and capillarization, and aerobic capacity were evaluated before and after 8 weeks of training (2 times/week). Results Muscle strength and quadriceps CSA were significantly and similarly increased ($p \leq 0.001$) after both interventions. Fiber CSA increased significantly and similarly after both RE (I:13.6±3.7%, II:17.6±4.4%, III:23.2±5.7%, p<0.05) and REC (I:10±2.7%, II:14.8±4.3% III:20.8±6%, p<0.05). In contrast, RFD was decreased and fascicle angle was increased ($p \leq 0.05$) only after REC. Significant negative correlations were found between the percent change in fascicle angle and the percent change in RFD at 50, 100, 150msec ($r = -0.54, -0.474, -0.46$; $p \leq 0.03$). Muscle capillary density and aerobic capacity were increased ($p \leq 0.05$) only after REC. Discussion The present findings suggest that high-intensity interval cycling performed after heavy-resistance exercise does not inhibit resistance-exercise induced muscle strength and hypertrophy, while it prompts cardiovascular and local muscle adaptations. However, the addition of high intensity cycling after heavy-resistance exercise may decrease RFD partly due to muscle architectural changes. CYCLING ON A BIKE DESK POSITIVELY INFLUENCES COGNITIVE PERFORMANCE AND BRAIN ACTIVITY

TORBEYNS, T., DE GEUS, B., BAILEY, S., DECROIX, L., VAN CUTSEM, J., DE PAUW, K., MEEUSEN, R.

Vrije Universiteit Brussel

Introduction Cycling desks as a means to reduce sedentary time in the office has gained interest as excessive sitting has been associated with several health risks. However, the question rises if people will still be as efficient in performing their desk-based office work when combining this with stationary cycling. Therefore, the aim of this study was to assess typing, cognitive performance and brain activity during low-intensity cycling on a bike desk. **Methods** After two familiarisation sessions, 23 adults performed a test battery (typing test, Rey auditory verbal learning test (RAVLT), Stroop test and Rosvold continuous performance test (RCPT)) with electroencephalography recording (N200, P300) while cycling at 30% Wmax (trial A) and while sitting on a conventional chair (trial B), in a counterbalanced order. Repeated measures ANOVA's and Wilcoxon signed ranks test were used to analyse the data ($p < 0.05$). Data are presented as mean \pm SD. **Results** Typing performance, performance on the RAVLT and accuracy on the Stroop test and the RCPT did not differ between the cycling and the sitting trial. Reaction times on the Stroop test (639.6 ± 22.5 ms vs. 663.1 ± 24.8 ms; $p = 0.01$) and the RCPT (377.9 ± 27.7 ms vs. 404.3 ± 36.4 ms; $p < 0.001$) were shorter while cycling relative to sitting. N200 amplitude during the Stroop test was larger in the cycling than in the sitting condition (-2.8 ± 0.3 μ V vs. -2.4 ± 0.3 μ V; $p = 0.028$). P300 amplitude during the RCPT was smaller in the anterior prefrontal cortex while cycling compared to sitting (2.0 ± 8.6 μ V vs. 6.6 ± 4.6 μ V; $p = 0.042$). **Discussion and conclusion** This study showed that typing performance and short-term memory are not deteriorated when people cycle at 30% Wmax, compared to when sitting on a conventional chair. In contrast to previous research, in this study, cycling had a positive effect on selective and sustained attention, as evidenced by the improved RTs on the Stroop test and the RCPT. These improvements were supported by the change in N200 during the Stroop test and P300 during the RCPT. The inclusion of familiarisation sessions in the current protocol is a possible explanation for these different findings on measures of sustained and selective attention, as familiarisation trials in previous studies were limited to maximum 15 minutes. The findings of this study suggest that implementing cycling desks in office settings could not only contribute to reducing health risks associated with excessive sitting, but could also result in improved cognitive performance, therefore work performance. THE EFFECT OF THE MEDIAL-LATERAL FORCE DURING CYCLING

FONDA, B., BABIC, J., SARABON, N.

University of Primorska

Introduction Body movement during cycling is kinematically constrained to the pedal/crank path around the bottom bracket and predominantly occurs in a sagittal plane. This limits cyclists optimising their pedalling technique by applying a force in two directions: vertically and in the anterior-posterior direction. Any medial-lateral force (FML) applied to the pedals is considered a waste and does not contribute to the pedalling. Previous research (Ruby et al., 1992) suggests that there is a certain amount of force that is exerted in the medial-lateral direction, but it remains unclear how this affects force effectiveness calculations and how it is linked to frontal plane kinematics. The aim of this study was to test the hypotheses that 1) FML would affect force effectiveness calculations, 2) FML would be different across different cadences and workloads and 3) FML would correlate with frontal plane kinematics of the leg. **Methods** 22 cyclists completed six testing trials at three different workloads (2, 2.5 and 3 W/kg) and three different cadences (75, 85, 95 rpm). During each trial, uni-lateral pedal forces (Cycling Science, Ltd) and lower extremity 3D kinematics (3D investigator, NDI) were recorded. Force effectiveness was initially assessed by using all three force components and then without the FML component. Relative FML was expressed as the percentage of the maximal value of the total force. The root mean square of the relative FML and absolute FML were used for further analysis. Additionally, cross-correlation coefficients between the Q-angle and relative FML were calculated. **Results** Index of effectiveness was significantly lower and total force was significantly higher ($p < .05$) under all conditions when the FML component was included in the calculations. Absolute FML was significantly different at different cadences and workloads. There was no significant difference in relative FML across the three cadences. However, there was a significant difference in relative FML at different workloads. Moderate correlation was found between the FML and Q-angle. **Discussion** The results of the present study confirm the hypotheses and demonstrate the importance of the FMF in the calculations of the total force applied to the pedals and consequently the index of effectiveness. Furthermore, medial-lateral knee movement could be one of the important factors for FML. This challenges the vast majority of biomechanical studies that examined force effectiveness by neglecting the FML component (Bini et al. 2014). Furthermore, the results demonstrate the importance of the FML for non-traumatic knee injuries. Therefore, future research should use technology that allows measuring all three force components at the pedal. References Bini RR, Diefenthäler F, Carpes F (2014) Int Sport J, 15(1), 96–112. Mini-Orals**MO-PM40 Training & Testing: Swimming/Tennis****SWIMMING COMPETITION AND THE SLEEPING PATTERN**

CONDE, J.1, ROBALO CORDEIRO, C.2, RAMA, L.3

Politecnico di Coimbra(1), Coimbra University(2,3)

Introduction The exercise has since long been recognized as a non-pharmacological strategy for the improvement of the sleep pattern. The type the duration, the intensity and the time of the day in which it's performed may condition changes in sleep pattern. In elite athletes is possible that more time of sleep leads to improvements in mental availability, capacity of reaction and perception of athletes in the state of physical recovery, improving muscle function and performance. Taking into account that the behavior of the human being depends a lot on the sleep-wake cycle, an athlete's performance depends both on the quality and the amount of sleep. **Methodology** Assess a control group consisting of 19 sedentary individuals and an experimental group consisting of 12 swimmers. These were assessed in the week with highest workout load at the end of the first cycle, corresponding to a micro cycle (week) of type impact with 10 workout sessions and a high volume, close to 60.000 meters swam. To all individuals was executed a polysomnography study class 1, which allows the monitoring of a large set of neurological, respiratory, cardiac, muscle and postural parameters, leading to completion

of sleep staging and its concrete knowledge. Results Differences were found in sleep NREM 2, NREM 3 and REM, with the swimmers showing a more shallow sleep (NREM of 53.77% versus 47.12% of sedentary) and the control group with greater amounts of sleep NREM 3 and REM (32.03% and 15.99% versus 27.53% and 11.96% on swimmers). Swimmers also showed less willingness to be in bed and then less sleep time. Sleep efficiency was higher in swimmers, although within the range considered normal in both groups. Conclusion The high level competitive swimmers are subjected to a regular and organized workout, have a lower willingness to sleep than individuals who don't practice sports. Such is due to a too short break between afternoon practice and morning practice. Both groups present normal sleep efficiency values, since athletes have a very high sleep efficiency, which translates into a better use of almost all the time available for sleep. Unlike what is described in other studies our athletes showed less sleep NREM 3 and REM, stages where the physical and cognitive recovery occurs more effectively. We conclude that athletes, on this workout plan are subjected to conditioned recovery indexes, which can jeopardize their performance, being recommended a reorganization of the workout temporality.

SWIMMING STROKE PARAMETERS AND THEIR EFFECTS ON PERFORMANCE

ERTAS DOLEK, B.

Ankara University

Stroke parameters and their effects on performance and efficiency is a subject of swimming studies for a long time. The purpose of this study was to investigate the relationship between stroke rate (SR), stroke count (SC) and performance due to the changes in heart rate (HR) and lactic acid (LA) levels of swimmers during a 4x(4x100m) front crawl (freestyle) main set of three consecutive training days. In this study, 7 male (age = 14.14 ± 1.07) and 4 female (age = 14.00 ± 0.00) international level swimmers were participated. Before the study, swimmers' detailed body analyzes have been taken. For male and female swimmers, height (H = 175.28 ± 4.02; 163.25 ± 5.56), weight (W = 69.94 ± 4.20; 58.97 ± 2.77), body mass index (BMI = 22.77 ± 1.56; 22.15 ± 0.86) and percentage of body fat (PBF = 14.3 ± 7.17; 25.05 ± 2.18) data are obtained (Mean ± Standard Deviation, respectively). During the study, SC (for every 100m), SR (for each 75th.m), HR (for the end of every 100m), 100m-lap-times (for each 100m LAP), LA measurements (for the end of every 4x100m) were measured. Relationship between SR, SC, HR, LAP and LA was calculated using Statistical Package for Social Sciences (SPSS) v. 22.0. A cut of point in all the statistical analyses has been taken as p≤0.05.

HOW TO CHOOSE DIVE FINS BY USING KNEE STRENGTH

TAI, Y.C., CHO, C.R., WU, C.M., WU, S.H., KUO, Y.C., TASI, F.C.

National Kaohsiung Marine University

Introduction In skin diving (SD), three main equipment are mask, snorkel and fins, one of them provides more efficiency propulsion during flutter kick to go forward are fins. Several studies indicate that knee strength(KS) positive increases fin swimming speed, elite kick skill gets more (Abe et al., 2014; Kunitson et al., 2015), but how to choose proper fins to reduce drag and save energy still confuse for most diver. Therefore, the aim of this study was to realize the influence between knee strength and five styles of fins performance in college beginners during 50m SD sprint. Methods Eighteen college beginners used knee extension/curl equipment to measure 1RM knee extension/flexion strength and summed up KS, according to the order assigned to low KS (n= 9; mean, age: 20.33yrs; height:160.06cm; body mass: 63.26kg; body fat: 27.29%; KS: 100.47kg, LKS) and high KS (n= 9; mean, age: 20.44yrs; height:174.08cm; body mass: 74.11kg; body fat: 19.93%; KS: 160.79kg, HKS)groups. Five popular fins, F1 (MARES X-STREAM), F2 (SCUBAPRO TWIN JET MAX), F3 (SCUBAPRO JET SPORT ADJUSTABLE), F4 (SCUBAPRO JET FIN) and F5(SCUBAPRO SEAWING NOVA GORILLA) were tested 50m SD sprint with balance order in each beginner. Repeat one way ANOVA was applied to analyze those data in LKS and HKS. Results After completed 50m SD sprint with each styles of fins, in LKS, velocities of F1, F2, F3, F4 and F5 were 0.91, 0.94, 0.98, 0.99 and 0.93m/s (F=459.09, P<.01), post hoc tests showed that F4>F1 and F5; F3>F1(P<.05). In HKS, velocities of F1, F2, F3, F4 and F5 were 1.07, 1.08, 1.14, 1.20 and 1.07m/s (F=975.72, P<.01), post hoc tests showed that F4>F1, F2 and F5; F3>F1 and F5 (P<.05). Discussion In both groups, we found higher body fat, slower fins speed in LKS, so body fat was inversely proportional to KS, and percent body fat did not contribute to any of the stepwise models to predict swimming performance (Cochrane et al., 2015), young highly trained swimmers had lower fat mass (Rossi et al., 2014), above researches agreed that lower body fat got more speed in our study. Furthermore, five styles of fins performance were some difference in both groups, F4 was the fastest fins than F1 and F5, but F2 was not significant difference in LKS, F4 allowed water to pass through the fins during the recovery stroke of the kick cycle, and prevented water from passing during the power stroke. This reduces efforts during the recovery stroke increasing kick efficiency (SCUBAPRO, 2015) and suitable to HKS. F2 were split fins made kick the fins very easy and greatly reduced the load on your ankles and leg, delivered optimum power with minimum effort (SCUBAPRO, 2015) suitable to LKS. BLOOD LACTATE ACCUMULATION DURING OPEN WATER SWIMMING EVENTS IN RELATION TO GENDER. A PILOT STUDY

ROZI, G.1, THANOPoulos, V.1, DOPSAJ, M.2, LAMPADARI, V.1, OKICIC, T.3

1: UOAPHED (Athens, Greece), 2: FSPE (Belgrade, Serbia), 3: FSPE (Nis, Serbia)

Introduction Open Water Swimming is challenging and special, compared to other endurance sports. Maglischo (2003) states that lactic acid levels in the muscle ranges between 1.0-2.0 mmol/L at rest and between 25-30 mmol/L during maximum effort lasting 1 minute or more. Lactic acid levels of long distance swimmers are usually in the lower part of this range. Lactate accumulation depends on swimming intensity, duration, frequency, the range of oxygen uptake and the muscle fiber type (Maglischo, 2003). The aim of the present study was to identify differences in lactate accumulation in the blood during a 5000m Open Water Swimming effort, between male and female swimmers. Methods The sample consisted of 5 male, aged 17.5±1.0 years and 6 female, aged 16.4±0.6 years. Lactate accumulation was measured in the 3rd and 10th minute of passive recovery and was analyzed with the portable analyzer Scout Lactate Germany. Heart rate was measured with a Polar device and performance time with a handheld stopwatch Seiko Water Resistant 10bar S140. The research was conducted during a Greek National Open Water Championship, held in June. Results Analysis of variance showed no statistically significant differences between the two genders for all measured variables. This may be due to the small sample as well as the fact that some of the participants were competing for the first time. Discussion What should be noted is that there were no particular differences in the blood lactate values between the two genders at 5000m. This finding leads to the conclusion that the energy production

mechanism might be similar in both genders. Future studies should focus on larger sample in order to achieve more accurate results.

EFFECTS OF SEX AND EXERCISE INTENSITY ON THE VO₂ KINETICS IN SUBMAXIMAL SWIMMING

REIS, J.1, MILLET, G.2, BRUNO, P.3, VLECK, V.3, ALVES, F.

1Universidade Europeia, Lisbon, Portugal 2Institute of Sport Sciences (ISSUL), Department of Physiology, Faculty of Biology and Medicine, University of Lausanne, Lausanne, Switzerland 3CIPER, BIOLAD –

Introduction The oxygen uptake kinetics (VO₂K) has been considerably less studied in females than in males and the literature has provided conflicting results regarding the differences between sexes. The aim of this study was to compare the VO₂K in front crawl between male and female swimmers in moderate and heavy intensity-domains. Methods Nineteen well trained swimmers (8 females mean ± SD; age 17.9 ± 3.5 yr.; mass 55.2 ± 3.6 kg; height 166 ± 5 cm and 11 males 21.9 ± 2.8 yrs; 78.2 ± 11.1 kg; 181 ± 8 cm) performed a discontinuous maximal incremental test (5 x 200 m swims with 30 s rest intervals for the determination of maximal oxygen uptake (VO_{2max}) and ventilatory threshold (VT) and two 600-m square wave transitions for both moderate (M; 80 %VT) and heavy (H; Δ25% [= VT + 0.25 x (VO_{2max} - VT)]) intensities in a 50m pool. Cardiorespiratory analysis was performed using a breath by breath gas analyser (K4b2, Cosmed, Italy) and swimming snorkel (Aquatrainer, Cosmed, Italy). The breath-by-breath were 1-s interpolated, time-aligned and averaged together to provide one representative set of data for each swimming intensity. For H swimming, the parameters of the VO₂k (t_{d1}, tau₁, A₁, t_{d2}, tau₂, A₂; i.e. time delay, time constant and amplitude of the primary phase and slow component, respectively) were determined using a bi-exponential model. For the M swimming the slow component was not considered. Results: The time constant of the primary component (tp) was not significantly different between sexes in both intensity domains and was also independent from swimming intensity (M: 15.1 ± 5.6 vs 14.4 ± 5.1 s; H: 13.5 ± 3.3 vs 16.0 ± 4.5 s, for females and males, respectively). Similarly the slow component in the heavy domain was not significantly different between female and male swimmers (3.2 ± 2.4 vs 3.8 ± 1.0 ml·min⁻¹·kg⁻¹). Discussion: The kinetics was similar between female and male swimmers at both moderate and heavy intensities. It has been reported that women have smaller hearts, smaller stroke volumes, cardiac outputs and haemoglobin concentration than men (Wiebe et al. 1998). Furthermore, they have smaller lung volumes and lower maximal expiratory flow rates (Harms 2006) and a less effective matching of the O₂ delivery and O₂ utilization (Murias et al. 2014). However, said lower oxygen delivery to the muscle and the cardiac and respiratory characteristics of women does not seem to affect the oxygen uptake kinetics in moderate and heavy swimming. METABOLIC AND STRUCTURAL EFFECTS OF WATER TRAINING ON LEFT VENTRICULAR HYPERTROPHYOLIC AND STRUCTURAL EFFECTS OF WATER TRAINING ON LEFT VENTRICULAR HYPERTROPHY

NEIVA, C.M.1,2,3,4, TERRA, G.2,4, ROSA, B.2,4, SANTOS, L.4, SILVA, G.4, TAVARES, M.4, CAMPOS, P.A.3, FAITORONE, M.2, TONELLO, M.G.M.2, CIOLAC, E.1, VERARDI, C.E.L., PESSO-FILHO, D.M.4, GARCIA, J.4,5

UNESP

Introduction- Left ventricular hypertrophy is a multiple etiology progressive disease, and disabling its carrier progressively until death. Recent studies have suggested that some models of physical training can have metabolic and physiological effects in favour of health carriers of this disease. Objectives - This study assessed the effects of Water training on the lipid profile and left ventricular structures in hyperlipidemic mice. Methods - Twenty-eight male LDLr/- mice were randomly separated into 4 groups: sed- entary, fed a standard diet (C); exercising, fed a standard diet (C+TRE); sedentary, fed a hyperlipidic diet (C+HL); and exercising, fed a hyperlipidic diet (E+HL). The exercising mice trained daily for 60 minutes during 60 days. After 48 hours of the end of the training period and 12 hours of rest fasting the animals were underwent euthanasia and the blood was collected for measuring the plasma levels of triglycerides, total cholesterol and its fractions (LDL, HDL, VLDL). The heart was removed and the left ventricle was weighed fresh to calculate the ratio left-ventricle weight (mg)/body weight (g). Results - The results showed that the training was more effective in improving lipid plasma levels when combined with a balanced diet, thereby confirming that it is essential to associate physical exercise and diet. The training protocol resulted in eccentric left ventricular hypertrophy in the standard-diet group and decreased interstitial collagen deposition in the myocardium of the high-fat-diet animals, which may indicate an improved diastolic function with consequent improvement in the systolic function. Discussion - It was observed that regular moderate aerobic exercise induce beneficial and prophylactic adaptations to heart which promoted a better health condition and prevention to diseases.

ANALYSIS OF ENDURANCE IN GERMAN ELITE SWIMMERS OVER THREE DECADES

HOFFMANN, C.

TU München

Introduction Many different distances, strokes, and highly intensive submersed phases lead to a diversified requirements profile in swimming. Endurance, however, remains one of the most important factors. The evaluation and improvement of aerobic capacity is an essential aspect of performance diagnostics. A standardized and well established test in swimming is the Pansold incremental step test. German swimmers were frequently criticized for a lack of basic endurance. Therefore, the aim of this study was to compare the Pansold test results of the German national swimming team with the results of former national teams. Methods In the Pansold test, swimmers have to undergo 5 incremental stages in their main discipline. The outcome is a specific lactate performance curve with three characteristic parameters: The maximum lactate level in test (L_{max}), "P 4,0" as a predictor of aerobic capacity in % of maximum speed, and the value "b", exponent in the function $y=ae^{bx}$, as indicator of gradient of the curve. Despite contradictory views of threshold concepts, Heck (2008) recommend fixed thresholds for comparison of performance curves. 500 data sets of the current national team are evaluated and compared with mean values presented in two publications of Pansold (1994) with 4000 analyzed tests and Rudolph (2000) with 1000 evaluated tests. There are specific data for every point of measurement and discipline. Results In every discipline, maximum swimming velocity increases during the three points of measurement. P 4,0 values decrease significantly from measure point to measure point in almost every discipline: On average from 90% to 86.7% to 85.7% of maximum speed at lactate level 4 among men, and from 94.0% to 92.6 % to 91.8% among women. L_{max} in the majority increases over the three points of measurement. The development of the value "b" is not consistent, but we can observe specific curve shapes for different disciplines. Discussion Based on these findings, we can conclude

that German swimmers today have less aerobic capacity but achieve faster velocity with higher lactate level. This confirms the opinion that German swimmers bring less basic endurance, but they swim faster with higher energetic expenditure. Perhaps this could be the reason for lower physical stress tolerance in several competitions on the same day. Higher endurance may be related to greater training distance and more extensive training at younger ages. References Heck H, Beneke R. (2008). Dt. Z. f. Sportmedizin, 59 (12), 297-302. Löllgen H. JUMP HEIGHT ANALYSIS ON TENNIS SERVE.

DOSSENA, F., ROSSI, C., LA TORRE, A., BONATO, M.

Università degli studi di Milano

Introduction Tennis serve has become one of the most important shots in modern tennis, allowing players to gain points with no or very short rallies. In order to gain maximal speed during tennis serve the contribution of both upper and lower limbs is necessary. In particular, lower limbs generates about 50% of the total force developed during the serve. On the other hand, limited information are available about lower limbs activity during tennis serve. Therefore, the aim of this study was to investigate possible relationship between the jump height and anthropometric characteristics during serve performance. Methods Eight professional tennis players, 4 elite (300-800 of ATP official ranking) and 4 professional tennis players (age 19 ± 4 y-o; height 181 ± 3 cm; height with racket 283 ± 5 cm) participated in the study. Players performed five first and 5 second balls and five first and 5 seconds serving on a 10 cm wood platform directly in the tennis court. Jump height during tennis serve was measured with a high-speed camera. Serve speed was measured with a radar apparatus placed 2 meters behind the player on the ideal serve trajectory axis. Serve efficacy was evaluated hitting a target zone in the middle of the serve area. In addition, three series of counter movement jump (CMJ) and counter movement jump free (CMJF) with high-speed camera to evaluate jump height were measured. Results Pearson correlation analysis showed a positive relationship between players height and jump height during the first serve ($R=0.8$; $P=0.03$). Unpaired t-test revealed that using both CMJ and CMJF elite tennis players used an high percentage of jump during the first (CMJ: 37 ± 4 % elite vs 27 ± 8 % professional, $p=0.02$; CMJF: $31 \pm 2\%$ elite vs $22 \pm 5\%$ professional, $p=0.004$), and second ball (CMJ: $38 \pm 5\%$ elite vs $29 \pm 5\%$ professional, $p=0.0003$; CMJF: $31 \pm 4\%$ elite vs $24 \pm 4\%$ professional, $p=0.0001$) of the serve. Moreover, during the second serve elite tennis players reached a higher jump height compared to professionals (13.6 ± 2.2 cm, elite vs 10.7 ± 2.3 cm professional, $p=0.001$). No significant difference in ball speed and efficacy between elite and professionals were detected. When serving on the wooden platform, elite players had a better efficacy in the first serve respect to professional players ($p=0.028$). Also in this situation no significant differences in ball speed between elite and professionals were founded. Discussion Reaching higher jump heights during tennis serve seems not to be effective both in the first both in the second ball. In addition, an acute improvement of height for serving was not an effective solution for improving ball speed and serve efficacy. This because, serve performance requires the coordinate action of several body segments to produce optimal racquet position, trajectory and velocity at ball impact. In conclusion, coaches of top-level athlete have to insist on serve technique rather than jump height. Contact filippo_dossena@yahoo.it

SPEED DOES NOT DISCRIMINATE WITHIN DUTCH TOP-30 U14 TENNIS PLAYERS

KRAMER, T., HUIJGEN, B.C.H., ELFERINK-GEMSER, M.T., VISSCHER, C.

HAN University of Applied Sciences, the Netherlands

Introduction Speed is important for tennis performance (Kovacs, 2006; Kramer et al., accepted). In U14 players, speed discriminates between players ranked top-8 and players ranked 9-150 in the Netherlands (Kramer et al., accepted). However, unknown is if speed discriminates between U14 players within an even more homogenous elite group, or whether it can predict future performance two years later. To improve talent identification, the aim of this study is to investigate whether speed relates to on court performance (i.e., ranking) at U14 in top-30 players. and how far it can explain ranking at U16. Additionally, players' stability in ranking from U14 to U16 is investigated. Methods Speed was measured in 44 boys and 42 girls (age $M=12.5$, $sd=.25$) with 5-and 10-meter sprint tests at U14. All players were top-30 ranked on the Dutch National ranking list at U14, and top-50 ranked at U16 Based on U14 ranking four quartiles were created, running from quartile 1 (ranking 1-5) to quartile 4 (ranking 15-30). The players were also grouped in 4 quartiles based on their ranking at U16. Differences between quartiles at U14 and U16 were analysed for boys and girls with the Kruskal Wallis test. Distribution of players in the quartiles at U14 and U16 were investigated using frequencies. Results In boys and girls, no differences were found between the quartiles at U14 nor at U16 in speed ($p>.05$). Comparison of the distribution over the quartiles at U14 with U16 showed that 26% of the boys reached a higher quartile, 40% was stable and 34% moved to a lower quartile at U16 compared to U14. In girls, 30% climbed to a higher quartile, 42% stayed equal, and 28% moved to a lower quartile. Discussion Speed does not discriminate within the top-30-ranked players U14. Around 40% of players were stable in their ranking in the subsequent two years. The others either increased or decreased in ranking. More research is needed to state which other aspects than speed should be taken into account for identifying players for talent development programs. References Kovacs MS. IMPACT OF ANTHROPOMETRIC CHARACTERISTICS AND PHYSICAL PERFORMANCE COMPONENTS ON SERVE VELOCITY IN ELITE MALE JUNIOR TENNIS PLAYERS

FETT, J., ULBRICHT, A., FERRAUTI, A.

Ruhr-University Bochum

Introduction In tennis, modern game has evolved from a primary technical to the current explosive sport becoming increasingly dynamic and faster based on strength, speed and power with higher stroke and serve velocities leading the service game to a key factor of game success. Consequently, velocity production is an obvious prerequisite to proficient tennis serve performance. However, there is no consent whether physical and anthropometric attributes are good predictors of service speed. Therefore, the aim of the study was to examine the impact of physical performance characteristics and anthropometric variables on serve performance (i.e. velocity). Methods 625 male junior squad players of the German Tennis Federation (13.7 ± 1.9 yrs, 165.4 ± 13.4 cm, 53.0 ± 13.7 kg) participated in this study. All subjects, matched into 2yrs age categories (U12, U14, U16, U18), performed the standardized German Physical Condition Tennis Test including body height [BHI], body mass [BMI], sitting height [SH], arm span [ASI], serve velocity [SVI], medicine ball throw [MBT] overhead [OHI], fore-

hand [FH], backhand [BH], hand grip strength [GS], countermovement jump [CMJ], horizontal jumps [HJ], 20m sprint [SI], and tennis-specific endurance [E] [1]. Partial correlation as well as multiple regression analysis was used to determine the relation and contribution of anthropometric and physical performance to service speed according to each age group. Results Among all groups, MBTs (U12 r=.49-.55, U14 r=.52-.63, U16 r=.58-.60, U18 r=.51-.55; p<.05) as well as GS (U12 r=.43, U14 r=.57, U16 r=.59, U18 r=.59; p<.05) showed the highest correlations to service speed. Concerning anthropometric data, BW (U12 r=.47, U14 r=.55, U16 r=.57, U18 r=.44; p<.05) and AS (U12 r=.44, U14 r=.56, U16 r=.56, U18 r=.37; p<.05) were the most correlated showing moderate to large values. Results of multiple regression analysis indicated values of R^2 ranging from 41-66% concerning the explained variance of criterion variable (U12 $R^2=.41$ (MBT OH+BH), U14 $R^2=.66$ (MBT FH+OH, GS, AS), U16 $R^2=.62$ (MBT OH+FH, GS), U18 $R^2=.46$ (MBT FH, GS), p<.00). Discussion Given a complex stroke as the tennis serve, results of regression as well as correlation analysis reinforce that service speed is strongly dependent on physical performance and anthropometric characteristics. Especially the upper body power/strength and the transfer of power from the lower to the upper body in proper timed sequences, which is needed in the MBT, highlight its importance for the junior player's service while the purely lower body power (e.g. CMJ) seems to be less important. In this regard, intervention programs focusing on the specific requirements are recommended to increase serve performance. References [1] Ulbricht A, et al (2015) J Med Sci Tennis, 20(1), 6-16. EFFECTS OF TRUNK MUSCLES FATIGUE ON SITTING BALANCE, KINESTEZIA AND LOWER LIMB STABILITY DURING SINGLE LEGGED LANDING

SARABON, N., ROSKER, J.

University of Primorska

Introduction Muscular endurance of the trunk muscles has been shown to be an important prevention factor for low back pain occurrence. However, it is unknown how fatigue of the trunk muscles affects other neuromuscular functions of the trunk, such as kinaesthetic sense and local/global dynamic stability. Therefore the aim of this study was to analyse, how fatigue of trunk flexors, extensors and latero-flexors affect sitting balance, trunk active joint repositioning sense and stability index during unilateral landing. Methods Twenty-four young healthy adult subjects completed three 30-s repetitions of sitting balance, three repetitions of active repositioning sense test for trunk (measured at the lumbar region during trunk flexion in standing position, at an angle of proximally 50% of maximal trunk flexion ROM) and three unilateral landings on the dominant leg (from 40 cm height, holding the landing position for 5 s). Sitting balance was analysed using mean sway velocity, average amplitude and frequency of the centre of pressure movement in anterior-posterior (a-p) and medial-lateral (m-l) direction. Averaged difference between the reference and the repositioned angle was used as a measure of active joint repositioning sense. And finally, common stability index, stability index in a-p, m-l and vertical direction were calculated for analysing stability in unilateral (standing dominant leg) landings. These three tests were followed by a fatiguing protocol, consisting of three sets of four exercises (curl-ups, trunk extension, side-curls on each side), performed to exhaustion. Immediately after the fatiguing protocol, subjects repeated the measures of sitting balance, kinesthesia and stability in unilateral landings. Results No statistically significant differences were observed between pre and post fatiguing conditions in sitting balance, kinesthesia or stability indexes during unilateral landing. However, an obvious trend of near to statistically significant increase was observed for m-l sway velocity and m-l average amplitude in sitting balance as well as a decrease in m-l stability index during unilateral landings. Discussion Our results indicate that sitting balance, kinesthetic sense and stability of the body during unilateral landings are unaltered following fatigue of the trunk muscles. This could be explained by central adaptations in motor control, possibly by a way of resetting the referent position (Feldman et al., 2013) remaining the sensory and motor functions intact. However, body sway in sitting balance and stability index in m-l direction could be affected more than in a-p direction. Further research is needed to understand whether trunk muscle fatigue causes direction specific changes. References Feldman AG, Ilmane N, Sangani S, Raptis H, Esmailzadeh N. (2013). Neuropsychologia, 51(13), 2590-2599.

IN-SEASON AND OFF-SEASON VARIATION IN PHYSICAL FITNESS PARAMETERS OF ELITE YOUNG SOCCER PLAYERS

BIDAURRAZAGA-LETONA, I.I, LEKUE, J.A.2, GIL, S.M.1

1University of the Basque Country (UPV/EHU), Department of Physiology, Faculty of Medicine and Nursing, Basque Country, Spain

2Medical Services, Athletic Club Bilbao, Basque Country, Spain

Introduction The assessment of physical fitness changes at various moments during the development of youth soccer players is of relevance to measure the effectiveness of training. As such, the aim of the present study was to describe the changes in physical fitness of elite young soccer players exposed to systematic training. Methods The present study involved a mixed cross-sectional and longitudinal analysis of the development of young soccer players of a professional soccer academy during three competitive seasons. The players started being part of the Under-12 (U12, n=55) category and, subsequently, they passed through the Under-13 (U13, n=39) and Under-14 (U14, n=27) categories. Players were evaluated annually at the beginning (September) and at the end (June) of the competitive season. The following variables were measured: 15 m velocity test, Yo-Yo intermittent recovery test (Level 1) (Yo-Yo IR1) and counter-movement jump (CMJ). A pairwise analysis was employed to establish the percentage change in the variables between consecutive sessions. A one way ANOVA was used to determine if there were any significant differences in the magnitude of the change across different ages. Only players with results for consecutive test sessions were included in each pairwise analysis. RESULTS As age increased significant improvements were observed in all the performance tests (p<0.001). Besides, a pronounced improvement was observed in all the tests during the U14 season (10.2 %, 51.0 % and 8.1 % for velocity, Yo-Yo IR1 and CMJ, respectively). In contrast, during the off-season between U13 and U14 categories decrements in Yo-Yo IR1 (-1.7%, p<0.01) and velocity (-4.1%, p<0.001) were found. Discussion The present results showed performance spurts in speed, endurance and jump that may occur at different moments depending on the maturation tempo and timing of the players. Indeed, previous research has shown that these improvements may be a contribution of the growth spurt related to the increases in body dimensions and muscle mass (Malina et al., 2004). However, an evident decrement in performance was observed in all the tests in the U13 off-season indicating a possible effect of detraining at this age. Altogether, this information can improve insight into the development of a specific group and can assist in an appropriate talent development program design. Acknowl-

edgements This study was supported by grants from the Basque Government (BFI2010-35 and IT700-13). References Malina RM, Bouchar C, Bar-Or O. (2004). Growth, maturation and physical activity. Human Kinetics, Champaign. Contact iraia.bidaurrazaga@ehu.eus

THE EFFECTS OF PERTURBATION TRAINING ON KNEE JOINT STABILITY IN FEMALE ATHLETES

YAO, H.I.1, HUANG, Y.T.1, CHOU, P.H.1,2

1 Kaohsiung Medical University, 2 Kaohsiung Medical University Hospital

Introduction Perturbation training has been shown to have benefits for patients receiving anterior cruciate ligament(ACL) reconstruction (Erin et al.,2010) . Female athletes are more prone to ACL injuries than male athletes. How to prevent ACL injury has been an important issue for athletes and coaches. Thus, the purpose of this study is to investigate the effects perturbation training on knee joint stability in female athletes. Methods Nine female basketball players with an average age of (23±2), an average height of (162.6±6), and an average weight of (54.7±7.4), completed five test sessions on nonconsecutive days within 2 weeks. Using the Bosu ball (BOSU® Official Global Headquarters, U.S.A.), four perturbation training sessions were administered (stand on unilateral and bilateral on the back and front Bosu ball each 1 minute). An elastic band under the tibial tuberosity was applied to all participants who volunteered for this training program. Pretest and protest measured 4 hop score (single hop , triple hop , cross hop , 6M hop),T shuttle run , proprioception by BiodexSystem 3, Biodex Medical Systems, New York, U.S.A.) and dynamic balance . Chi-square tests was used for statistical analysis. Results The single hop score (m) improved significantly in the before training conditions (1.19±0.14) as compared to after training conditions (1.278±0.11 , p<0.05). For the triple hop score and cross hop score, there was no significant differences between the before and after training sessions. The 6M hop score (sec.) improved significantly in the before training conditions (2.68±0.29) as compared to after training conditions (2.36±0.34, p<0.05). The T shuttle run (sec.) improved significantly before training conditions (12.23±0.94) as compared to after training conditions (11.43±0.66 , p=0.006) . The proprioception by Biodex and dynamic balance were showed no significant differences between before and after training condition . Discussion The results of this study showed that perturbation training improved knee joint stability in female athletes. These information may be beneficial for the athletes and coaches. Therefore, perturbation training may be included in the general training program to prevent ACL (anterior cruciate ligament) injury in female athletes. References Erin H. Hartigan , Michael J. Axe , and Lynn Snyder-Mackler. J Orthop Sports Phys Ther. 2010 March ; 40(3): 141–154. doi:10.2519/jospt.2010.3168. Contact E-mail:Pokeryao11@gmail.com

STRENGTH AND ENDURANCE TRAINING REDUCES THE LOSS OF ECCENTRIC HAMSTRING TORQUE OBSERVED AFTER SOCCER SPECIFIC FATIGUE

MATTHEWS, M., HERON, K., TODD, S., TOMLINSON, A., JONES, P., DELEXTRAT, A., COHEN, D.

University of Salford

Purpose: To investigate the effect of two types of hamstring training protocols on parameters of eccentric peak torque before and after soccer specific fatigue. Participants: 20 university level male soccer players; mean (\pm SD) age, height and body mass were 22.5 ± 3.4 years, 182.1 ± 7.5 cm and 80.9 ± 10.4 kg respectively. Method: Isokinetic strength tests at $60^\circ/\text{s}$ pre and post fatigue, before and after 2 different training interventions. A 45-minute soccer specific fatigue modified BEAST protocol (M-BEAST) was used to induce fatigue. Players were randomly assigned to a 4 week hamstrings conditioning intervention with either a maximum strength (STR) or a muscle endurance (END) emphasis. Results: There was a significant effect of the M-BEAST on the Eccentric torque angle profile before training, as well as significant improvements in post-fatigue torque angle profile following both strength and muscle endurance interventions. Conclusion: 45 minutes of simulated soccer activity leads to reduced eccentric hamstring torque at longer muscle lengths. Short-term conditioning programs with either a max strength or a muscular endurance emphasis can significantly reduce fatigue induced loss of strength over this time period.

THE LONG-TERM ERGOGENIC EFFECT OF LONG ACTING B2-AGONISTS

MERLINI, M., WHYTE, G., CHESTER, N., LOOSEMORE, M., MARCORA, S., DICKINSON, J.

University of Kent

Background: The WADA List of Banned Substances and Methods stipulates that athletes can use up to 54 µg inhaled Formoterol and inhaled Salmeterol as directed by the manufacturer. It is unknown whether large daily therapeutic doses of Formoterol and Salmeterol can improve sprint and strength performance. Purpose: To investigate the impact of inhaling 100 µg of Salmeterol (SAL) or 12 µg of Formoterol (FOR) twice daily over a 5 week period on sprint, strength and power performance. Methods: In a randomised single blind study 24 male and 15 female non-asthmatic and active participants were recruited (mean \pm SD; Males age 28.0 ± 5.5 years; weight 72.1 ± 10.5 Kg; height 164.7 ± 7.1 cm; Females age 24.1 ± 4.1 years; weight 65.4 ± 9.5 Kg; height 168.0 ± 4.3 cm). Participants completed three standardised whole body strength and power training sessions per week for five weeks. All the training sessions were supervised by a personal trainer who recorded work performed in each session. During the five week training period participants were assigned to either SAL, FOR or a placebo (PLA) group. Participants took their inhaler twice per day as instructed. Participants completed assessments of sprint, strength and power at week 0 and after 5 weeks of strength and power training. The assessments included 30 m sprint, vertical jump, 1 RM bench press, 1 RM leg press, peak torque flexion and extension, anthropometric evaluation and Rest-Q questionnaires. Mixed Model Repeated Measures ANOVA were performed to investigate the changes in the sprint, strength and power assessments between groups over the course of the 5 week training session. Results: 30 m Sprint time was significantly lower in FOR group (-0.29 ± 0.11 s; $p=0.049$) and SAL (-0.35 ± 0.05 s; $p=0.04$) when compared with compared with Placebo ($+0.01 \pm 0.11$ s; $P=0.000$). No significant change was found in 1RM Leg, Squat and Bench Press or during Isokinetic evaluation performed at 60° range in flex/ext movement. Jump performance as well as anthropometric measures didn't differ between groups. Discussion: The significant changes in FOR and SAL 30m sprint time when compared to PLA suggest the long term use of inhaled β_2 -agonists may provide ergogenic advantage. This finding suggests a review of the use of inhaled doses of FOR and SAL by athletes in training and official competition may be necessary.

RELATIONSHIPS BETWEEN TRAINING LOAD AND PHYSICAL FITNESS' CHANGES IN PROFESSIONAL AND SEMI-PROFESSIONAL BASKETBALL PLAYERS

FERIOLI, D.1,2, BOSIO, A.1, CARLOMAGNO, D.2, AZZOLINI, M.2, LA TORRE, A.1, RAMPININI, E.2

1 Università degli Studi di Milano, Milan, Italy 2 Mapei Sport Research Center, Olgiate Olona, Italy

INTRODUCTION Quantification of training load (TL) is essential for monitoring an effective training process. To date few studies have analyzed different methods to determine TL in basketball (Manzi et al., 2010; Scanlan et al., 2014) and no studies verified the relationships between TL and changes in players' fitness level. Furthermore, there is limited information regarding the TL sustained by players of different competitive levels. The aim of this study was to quantify the perceived TL in professional and semi-professional basketball players and to determine its relationship with changes in physical fitness during the preparation period. **METHODS** Thirty-two professional (n=14, age: 25.6±6.0 yrs, height: 198±10 cm, weight: 95.5±13.0 kg) and semi-professional (n=18, age: 23.3±4.7 yrs, height: 190±9 cm, weight: 82.2±11.6 kg) basketball players participated in the study. Players performed Yo-Yo intermittent recovery level 1 (YIR1) and counter-movement jump (CMJ) tests before and after the preparation period. In addition, physiological responses to a standardized 6-min continuous running (Mognoni's test) and to a standardized 5-min high-intensity intermittent running test (HIT) were measured. The players' perceived TL was assessed using the session rate of perceived exertion method. All data were analyzed using magnitude-based inferences. **RESULTS** Almost certain differences were found for weekly TL and training volume (TV) between professional and semi-professional players (TL: 5241±1787 vs 2408±487 AU, effect size (ES)=1.49±0.46; TV: 914±122 vs 634±71 min, ES=2.17±0.49). Very likely moderate relationships were observed between TL and changes in La- ($r=-0.48\pm0.23$) and H+ ($r=-0.42\pm0.25$) measured after HIT. Very likely moderate relationships were also found between TV and changes in absolute ($r=-0.39\pm0.25$) and relative ($r=-0.41\pm0.25$) peak power produced during CMJ. No clear relationship was found between TL or TV and changes in YIR1 and Mognoni's test. **DISCUSSION** The present results suggest that a low TL in basketball entails a small physiological adaptation to submaximal intermittent running but not to submaximal continuous running or maximal intermittent performance (YIR1). Conversely, high TV can negatively affect CMJ performance during the preparation period. Future studies should investigate the effect of TL on changes in physical fitness during the competitive season.

TRAINABILITY OF SPRINTING IN YOUTH MALE AND FEMALE SOCCER PLAYERS

MATHISEN, G.

University of Tromsø

Do not insert authors here **Introduction:** Sprinting and change of direction sprints (agility) is important for youth soccer players. Compared to adult athletes there is less information about the effectiveness of sprint training in youths. The aim of the present study was to examine the trainability of sprint and agility performance in male and female youth soccer players. **Method:** This present study is a collection of four intervention programs, with 10 to 13 year-old boys, and 13 to 15 years-old girls. In total, 57 subjects (34 boys and 23 girls participated in the intervention programs. The training sessions involved running in short burst with starting, stopping, change of direction, and linear sprints, all executed with maximal effort. Control groups followed ordinary soccer training sessions. The sprint test consisted of 20 m straight-line course, and the agility (change of direction sprint) test was a 20 m standardized course with 90° and 180° turns. Electronic timing gates, wireless connected with a timer was used to record the times (Brower Timing System, US). **Results:** Training groups showed significant improvement in 20 m sprint ($p<0.05$): 10.5 (± 0.2) year old boys 20 m from 3.96 (± 0.24) to 3.89 (± 0.21); 13.5 (± 0.2) year old boys; from 3.54 (± 0.17) to 3.42 (± 0.18); 13.6 (± 0.2) years-old girls; from 3.75 (± 0.15) to 3.62 (± 0.22), 15.5 (± 0.7) year old girls from 3.53 (± 0.15) to 3.42 (± 0.16). Training groups showed significant improvement in agility performance ($p<0.05$): 10 year-old boys from 9.15 (± 0.57) to 8.42 (± 0.39), 13-years-old boys from 8.23 (± 0.34) to 7.69 (± 0.34), 13 years-old girls from 8.56 (± 0.54) to 8.03 (± 0.38), 15 year-old girls from 8.23 (± 0.31) to 7.80 (± 0.33). **Discussion:** Faster completion of sprinting indicates that the intervention programs consisting of short burst high-speed exercises is effective in youth soccer players. The results are in line with previous findings with youth athletes, showing improved sprint performance with high-intensity speed training, and programs that are specific to the performance tests. The improvement is supposed to be due to that neuromuscular adaptions including recruitment, activation of motor units and better coordination of muscles have occurred. IMPACT OF A STRENGTH TRAINING PROGRAM ON FOOTBALLERS' VO₂MAX

IBO, B.J., CHEVALIER, J., COMTOIS, A.S.

Université du Québec à Montréal

Introduction There is considerable variation between football players' BMI and players of other sports such as rugby, hockey or American football. Nonetheless, that contrast is dwindling when it comes to body fat percentage and cardiorespiratory capacity. Many football specialists still believe that hypertrophy will alter footballers' efficiency. However, players from the aforementioned sports succeed in their respective disciplines. The main purpose of this study is to put elite footballers through a resistance training program and demonstrate that this type of training is not deleterious to the footballers' VO₂max. The second objective is to verify hypertrophic gains while examining the impact of the program on the players' other attributes. **Methods** The study was conducted on the U-19 players from the academy of professional football club Asec Mimosas; 20 subjects participated in the study (N = 20). A total of seven tests were performed to measure various components: BMI, Body fat percentage, VAMEVAL test, 30m dash, RSA, Illinois test and broad jump test. The experimental design consisted of a single group, with pre and post measures. All results are reported as standard deviation (SD). Results were compared using a paired Student's T test and accepted as significant at $P<.05$. The resistance training program protocol: The idea was to develop a 45 to 60 minute in-season training protocol that required minimal equipment. It was also essential that the program involved a majority of various muscle groups. Hence the implementation of functional movement training program followed twice a week. The program was divided into 3 circuits. Circuit 1: Bench Press, DB Rows and Side Plank. Circuit 2: Squats, Hip Thrust, and Pullups. Circuit 3: Deadlift, Overhead Press and Plank. Players performed 3 sets of 5 to 10 reps. Results BMI ($p=.0001$) from 20.7±1.6 to 21±1.6 kg/m²; Body fat percentage ($p=.0001$) from 9.8±1.4 to 8.2±1.2 %; Lean body mass ($p=.0001$) from 57.5±5.7 to 59.5±6.1 kg; 30m sprint ($p=.0001$) from 4.22±0.1 to 3.98±0.2 s.; RSA ($p=.0001$) from 4.46±0.2 s. to 4.25±0.2 s.; Broad jump ($p=.009$) 2.31±0.1 to 2.45 ± 0.2m; Illinois test ($p=.001$) from 15.69±0.1s to 15.16 ± 0.1s.; VO₂max from 58.78 ± 0.6 ml/mn/kg to 59.6 ± 0.6 ml/mn/kg **Discussion** The findings suggest that resistance training is not deleterious to footballers' VO₂max. For this reason, once elite players reach VO₂max standards, it is necessary to imple-

ment a good in-season resistance training program that will help improve VO_{2max}, lean body mass, body fat percentage and other footballers' important qualities such as speed, RSA, agility and leg.

THE EFFECTS OF FIVE WEEKS OF HIGH-INTENSITY INTERVAL TRAINING ON PERCEPTUAL AND LACTATE RESPONSES IN FEMALE FUTSAL PLAYERS: A COMPARISON BETWEEN THE TWO MODELS

DITTRICH, N., ARINS, F.B., TEIXEIRA, A.S., CARMINATTI, J.L., DE LUCAS, R.D., GUGLIELMO, L.G.A.

Federal University of Santa Catarina

Introduction The purpose of this study was to compare the effects of two models of high-intensity interval training (HIIT) performed over five weeks, on the perceptual and blood lactate responses in elite futsal players. Methods Sixteen female futsal players (divided in two groups) performed the Futsal Intermittent Endurance Test (FIET) to determine the peak velocity (PVFIET). Both training models (twice a week during five weeks totaling 10 sessions) were designed from shuttle running intervals and consisted of four sets of 4-minute bouts with 3-minutes of rest intervals between the sets. The difference between the two models was the intermittence timing in each set, one being performed by 7.5s of running and 7.5s of resting (HIIT7.5x7.5), and the other by 15s of running and 15s of resting (HIIT15x15). The intensity used for the HIIT7.5x7.5 was ~ 88 %PVFIET and for the HIIT15x15 was ~ 85 %PVFIET. The blood lactate concentration [La] following each set and a session rating of perceived exertion (RPE) were assessed during the second and tenth training sessions. Results There were no "training model x time" interactions and main effect for the training model ($p>0.05$) regarding the RPE score. However, significant main effect findings were found for time ($F=25.52$, $p<0.001$) showing that RPE score was reduced from 2nd to 10th training sessions (HIIT7.5x7.5 = 4.3 ± 0.8 vs. 2.4 ± 1.1 au; HIIT15x15 = 4.1 ± 0.4 vs. 2.9 ± 0.6 au, respectively). The ANOVA results also indicated a non significant three-way interaction effect ($p>0.05$) for lactate responses. However, a significant "time x sets" interaction ($F=12.25$, $p=0.002$) was found for lactate responses. After the training period, the blood [La] following each set was similarly reduced in both HIIT7.5x7.5 and HIIT15x15 groups. Thus, the progressive increase in the blood [La] over the 4 sets shown in the 2nd session was not observed in the 10th session, displaying a steady-state pattern between the sets. Discussion The present study compared the two models of HIIT performed in shuttle running derived from FIET. The main hypothesis was that the model with more changes of direction (i.e. HIIT15x15) could trigger greater improvements in perceptual and lactate responses. In conclusion, the completion of the 10 training sessions in both HIIT models may elicit similar improvements in perceptual and lactate responses in female futsal athletes. MO-PM36 Recovery Methods

EFFECTS OF KINESIO TAPING ON LOWER EXTREMITY SKIN TEMPERATURE IN YOUNG SOCCER PLAYERS

GULSEN, M., PEKYAVAS, N.

Baskent University

M. Quadriceps Femoris and M. Gastrosoleus are the major muscles at lower extremity, facilitating these muscles are very important for prevention of injury. Thermographic imaging can help to assess the skin temperature of these muscles as skin temperature is an important parameter for the assessment of the injured muscle. Purpose: To compare the effects of Kinesio Taping (KT) on skin temperatures of Quadriceps (Q) and Gastrosoleus (GS) muscles in young soccer players. Methods: Eighteen young soccer players were randomly divided into 2 groups [KT Group (n=9), & Control Group (n=9)]. Players were assessed before, 45 min. after the application and at the end of the training. KT Group received bilateral KT facilitation muscle technique for Q and GS muscles. Assessments included the sociodemographic parameters and thermographic assessment of bilateral Q and GS muscles. Results: Statistically significant differences were found between groups at 45 min after application (Right Q p= 0.000, Left Q p=0.008, Right GS p=0.008, Left GS p=0.004). When comparing three assessments (time factors) within groups, statistically significant differences were found between time factors ($p<0.05$). These differences were significant in favor of KT group results. Conclusion: KT seems very effective in regulating skin temperature of lower extremity muscles after application and training. This simple application may be used as a prevention for injuries that occur during training.

KINESIOLOGY TAPE: PATIENT PERCEPTIONS IN THE REDUCTION OF PAIN

CATLOW, S., DOGGART, L.

University of St. Mark and St John

Kinesiology Tape: Patient perceptions in the reduction of pain Introduction The justification for using Kinesiology Tape (K Tape) as a pain relieving ergogenic aid, post injury, remains uncertain (Williams et al. 2012) with its effects still being established (Lim and Tay, 2015). The aim of the study was to investigate patient's perceptions of K tape in the reduction of pain post injury. Method Following University ethical approval a focus group informed the development of a 17 point questionnaire around the perceived magnitude and timing of pain reduction. The questionnaire was posted on social media sites inviting patients, who had used K tape specifically for pain relief (inclusion criterial), to complete. Results One hundred and fifty two replies were received (male =57; female = 93). One hundred respondents (67.5%) reported using K tape to reduce pain following an injury that occurred in a sport or exercise activity. The most common site for the application of K tape was the lower limb (53.3%) while the back and upper limb recorded 15.8% and 14.5% respectively. A total of 113 (74.8%) respondents noted an immediate perceived reduction in pain (within 60mins) whilst 147 (96.7%) noted a reduction of pain within 48hrs. Seventy nine (52.3%) respondents noted an overall pain reduction of 50% or more. Of those who experienced a reduction in pain 76.8% also had additional treatment. Respondents further reported: reduced pain during load bearing activity; improved posture; reduction in swelling; improved circulation; increased support and cushioning; and increased mobility. Discussion A perceived immediate reduction in pain was noted from the results. The combination of pre-treatment and K tape application could influence the immediate reduction in pain and its magnitude. The results suggest that the site of application does not appear to affect the perceived influence on pain reduction however application technique and tape quantity could be influencing factors based on the purported mechanisms of K tape (Wil-

liams et al., 2012). Respondent's comments imply a confidence in the treatment process that could be credited to the K tape post treatment. The use of K tape to maintain the effects of the therapists' treatment would seem valuable. Rehabilitation practitioners can be confident that K Tape is beneficial based on patients' perceived reduction in pain. References Lim ECW and Tay MGX (2015). Kinesio taping in musculoskeletal pain and disability that lasts for more than 4 weeks: is it time to peel off the tape and throw it out with the sweat? British Journal of Sports Medicine.0: 1-15. CLINICAL-LIKE CRYOTHERAPY PROTOCOL ATTENUATES OXIDATIVE DAMAGE MARKERS FOLLOWING SKELETAL MUSCLE INJURY IN RATS

SIQUEIRA, A.F., VIEIRA, A., RAMOS, G.V., MARQUETI, R.C., SALVINI, T.F., PUNTEL, G., DURIGAN, J.L.Q.

University of Brasilia

The action of reactive species following skeletal muscle injury may lead to damage of cellular structures, amplifying the quantity of tissue damaged. The greater the quantity of damaged tissue, the longer it takes to recover. Cryotherapy is commonly used in the management of skeletal muscle injuries, but little evidence about its potential mechanism reducing post-injury oxidative damage is available. Therefore, the aim of this study was to investigate the effects of multiple cryotherapy application on markers of oxidative damage and levels of antioxidants enzymes post skeletal muscle injury. This study was divided into 3 experimental analysis periods: 3, 7 and 14 days after freezing injury of Tibial Anterior (TA) muscle. Thirty-five Wistar rats were equally and randomly distributed into 7 experimental groups: control - no interventions; TA injured, analyzed 3, 7 and 14 days after injury; and TA injured, treated with cryotherapy, analyzed 3, 7 and 14 days after injury. A clinical-like cryotherapy protocol was performed immediately, 24 and 48 h after injury. Crushed ice was applied three times a day for 30-min, every two hours. Diclorofluoresceine reactive substances (DCF-RS), thiobarbituric acid reactive substances (TBARS) and methyl thiazol tetrazolium (MTT) were measured as markers of oxidative damage. Catalase (CAT), superoxide dismutase (SOD) and non-protein thiol (-SH) were measured as markers of antioxidant system defense. DCF-RS levels were 10% lower 7 days and 30% lower 14 days post-injury in cryotherapy groups compared with non-treated ($p < 0.05$). Animals treated with cryotherapy also demonstrated TBARS levels 40% and 50% lower than non-treated animals 3 and 7 days post-injury, respectively ($p < 0.05$). In addition, cryotherapy maintained MTT levels within control range in all analyzed time points ($p > 0.05$), whereas non-treated groups demonstrated higher levels than control group. It were observed lower SOD activity 7 and 14 days post-injury ($p < 0.05$) as well as also lower CAT activity 3 days post-injury ($p < 0.05$) in cryotherapy groups. Cryotherapy prevented the reduction in -SH levels 3 days post-injury ($p = 0.92$). Cryotherapy reduced the quantity of reactive species (DCF-RS), lipid peroxidation (TBARS) and increased cell viability rate (MTT) compared with non-treated. Cryotherapy also limited the reduction in -SH, and the increase in CAT and SOD activities. This results suggest that lower antioxidant response may be associated with lower oxidative damage. In summary, this findings suggest that multiples application of cold during the early phase of regeneration is an efficient strategy to reduce markers of oxidative damage.

THE EFFECT OF LOCAL CRYOTHERAPY AFTER EXERCISE INDUCED INDICES OF MUSCLE DAMAGE ON SUBJECTIVE AND OBJECTIVE RECOVERY CHARACTERISTICS: A RANDOMIZED CONTROLLED TRIAL

HOHENAUER, E., CLARYS, P., CLIJSEN, R.

University of Applied Sciences and Arts of Southern Switzerland

The purpose of this randomized controlled trial was to investigate the effects of local cryotherapy on recovery characteristics during 72 h. Twenty-two female ($n = 17$, mean age: 21.9 ± 1.1 yrs) and male ($n = 4$, mean age: 25.4 ± 2.8 yrs) adults participated in this study. After the exercise-induced indices of muscle damage (EIMD, 3 x 30 countermovement jumps) protocol, half of the participants received either a single local cryotherapy ($+8^\circ\text{C}$) or a single local thermoneutral application ($+32^\circ\text{C}$), each 20 min with two thigh cuffs. Subjective recovery characteristics (delayed-onset of muscle soreness and ratings of perceived exertion) and objective recovery characteristics (vertical jump performance and peak power output) were assessed immediately after the application (0 h) and 24, 48, and 72 h after the EIMD protocol. Cryotherapy failed to significantly affect any subjective recovery variable during the 72 h recovery period ($p > 0.05$). After 72 h, perceived exertion ratings reached baseline values in the thermoneutral group but not in the cryotherapy group. No significant differences could be observed between cryotherapy and the thermoneutral application for accelerating any objective recovery variable. In this experimental study, a 20 min of cryotherapy cuff-application failed to positively affect recovery characteristics.

COLD WATER IMMERSION $<8^\circ\text{C}$ MEDIATES GREATER REDUCTIONS IN LOWER LIMB BLOOD FLOW AND MUSCLE TEMPERATURE COMPARED TO WHOLE BODY CRYOTHERAPY $<-110^\circ\text{C}$ AFTER ENDURANCE EXERCISE

MAWHINNEY, C., LOW, D.A., JONES, H., GREEN, D.J., COSTELLO, J., GREGSON, W.

Liverpool John Moores University, Aspire Academy, University of Western Australia, University of Portsmouth

Introduction: Cryotherapy is a widely used recovery method to limit exercise-induced muscle damage and soreness as well as functional deficits after strenuous exercise. Typical methods include cold-water immersion (CWI) and whole body cryotherapy (WBC), the former of which exposes the body to cold water temperatures ($\sim 10^\circ\text{C}$) for ~ 10 min, while the latter of which exposes the body to very cold air (-110 to -140°C) for short durations (2-4 min). It is currently unknown which intervention mediates the greatest reduction in blood flow of the previously exercised limbs. This is important given that reducing blood flow may directly limit muscle damage and function, thus aiding recovery. The aim of this study was, therefore, to compare the effects of ecologically valid CWI and WBC protocols on post-endurance exercise thermoregulatory, femoral artery and lower limb cutaneous blood flow responses. It was hypothesised that greater reductions in lower limb muscle temperature, femoral artery and cutaneous blood flow responses would occur after CWI. **Methods:** Ten males completed a continuous cycle exercise protocol at 70% maximal oxygen uptake until a core temperature of 38°C was attained. Participants were then exposed to CWI (8°C) for 10 min or WBC (-110°C) for 2 min in a randomised cross over design. Rectal and thigh skin, deep and superficial (3,2,1, cm) muscle temperatures, thigh and calf skin blood flow (laser Doppler flowmetry), superficial femoral artery blood flow (duplex ultrasound) and arterial blood pressure (automated sphygmomanometry) were measured prior to and for 40 min post cooling interventions. General linear model repeated measures ANOVA were used to evaluate responses to CWI and WBC conditions. **Results:** Greater reductions in thigh skin (CWI, $-5.9 \pm 1.8^\circ\text{C}$; WBC, $0.2 \pm 0.5^\circ\text{C}$; $P < 0.001$) and superficial (CWI, $-4.4 \pm 1.3^\circ\text{C}$; WBC, $-1.8 \pm 1.1^\circ\text{C}$; $P < 0.001$) and deep (CWI, $-2.9 \pm 0.8^\circ\text{C}$; WBC, $-1.3 \pm 0.6^\circ\text{C}$; $P < 0.001$) muscle temperatures occurred after CWI. Decreases in femoral artery conductance were greater after CWI (CWI, $-84 \pm 11\%$; WBC, $-59 \pm 21\%$, $P < 0.02$) and greater thigh (CWI, $-80 \pm 5\%$; WBC, $-59 \pm 14\%$, $P < 0.001$) and calf (CWI, $-73 \pm 13\%$; WBC, $-45 \pm 17\%$, $P < 0.001$) cutaneous vasoconstriction was observed following CWI. Reductions in rectal temperature were

similar between conditions (CWI, $-0.6 \pm 0.4^\circ\text{C}$; WBC, $-0.6 \pm 0.3^\circ\text{C}$; $P = 0.98$). Conclusion: CWI may be more effective than WBC in the treatment of exercise-induced muscle damage and injury rehabilitation by virtue of greater reductions in blood flow and tissue temperature.

EFFECTS OF COMPRESSION GARMENTS ON CARDIAC OUTPUT AND LEG BLOOD FLOW DURING EXERCISE

WACHSMUTH, N.B., REIM, F., BAUER, F., GALEWSKI, P., MAASEN, N., SCHMIDT, W.

Institute of Sports Science

Introduction Compression garments are frequently used by elite and recreational athletes, although the effects on performance are controversially discussed. Postulated effects are an enhanced oxygen supply including higher VO_{2max} which is supposed to be due to an increased cardiac output (CO) and improved muscle perfusion. Therefore, the aim of the study was to compare VO_{2max}, CO and blood flow of the calves during exercise with and without leg compression. Methods 16 male triathletes and cyclists (VO_{2max}: 64.7 ± 7.3 ml/min/kg, age: 25.5 ± 3.5 years) participated at the study. Every athlete completed in total 4 randomized tests on a cycle ergometer (2 incremental tests until exhaustion and 2 submaximal tests (60% of VO_{2max}, 35min) each of them with (C) and without (noC) compression of both legs including the thigh (CEP, medi, Germany). CO was measured before (orthostatic test), at the end of the incremental test and during the submaximal test by rebreathing a gas mixture consisting of N₂O/SF₆/O₂ (Innovision, Denmark). Calf blood flow was determined by venous occlusion plethysmography at rest, during submaximal and immediately after submaximal and maximum exercise. Results No difference in performance was found (VO_{2max}, Watt, blood lactate) between C and noC. However, a marked increase of muscle blood flow was determined with compression at maximal (C: 19.9 ± 3.7 ml/100g, noC: 15.4 ± 5.4 ml/100g, $p < 0.01$) and submaximal (C: 21.6 ± 5.2 ml/100g, noC: 17.8 ± 5.6 ml/100g, $p < 0.05$) exercise. CO was significantly elevated in the orthostatic test with compression (C: 7.8 ± 1.4 l/min, noC: 7.2 ± 1.2 l/min, $p < 0.01$), showed no difference at maximum exercise and a trend to higher values (C: 21.6 ± 3.6 l/min, noC: 20.7 ± 3.1 l/min; $p = 0.08$) during the submaximal test with compression. Conclusion Although no impact of compression clothing on performance was found, physiological effects can be demonstrated. The blood perfusion of the legs was increased by 30% and CO tended to be elevated during submaximal exercise. This might be explained by a pronounced Bayliss effect and by an increased venous return. If the higher perfusion under compression is mainly due to higher skin or muscle blood flow cannot be decided here. Furthermore, the lack of increased performance remains to be clarified. FEMALE PRACTICE IN SCHOOL SPORTS: A MULTIPLE CASE STUDY IN BARCELONA AND NOTTINGHAM

FRANCO SOLA, M., FIGUERAS COMAS, S., GUERRA BALIC, M., HINDLEY, D., MILLS, N.

Universitat Ramon Llull

Introduction This is a multiple case study of three schools located in the cities of Barcelona and Nottingham, with participants from both sexes (ages = 10 - 16 years old). The aim of the study is to detect their practice and perceptions in relation to school sport. Methods The methodology is a mixed method (Creswell & Plano-Clark, 2007) using quantitative and qualitative data for combination (Bericat, 1998). The qualitative data help deeper and better refine the quantitative results of the first phase. The instruments are a questionnaire ($N = 610$), piloted and validated, and 4 focus group, designed with the results of the first phase. The quantitative data analysis consists of frequency descriptive statistics, using SPSS v.22. Qualitative data was analyzed by the Grounded Theory, with CAQDAS ATLAS.ti v.7.1.8. Results Girls' school sports practice is lower than boys, both in Barcelona (90% boys and 76% girls) and in Nottingham (80% boys and 64% girls). The data showed the influence from the peer group and the gender stereotypes (e.g., 'girls don't play football'). Results also showed that they have few female models in the media and even that models often contain sexist connotations favoring feminine stereotypes. For the other hand, both countries, girls practice a greater variety of sports than boys due to the influence of the social environment, due in particular to the media. Discussion We agree with López Crespo (2001) who affirm the important influence that the media have on children and young people in the sport, causing more male sports television references than female. In addition, media should provide a more positive image of women in sport, diversified and away from prejudice and gender stereotypes (British Sport Council, 1994). Data also showed that stereotypes are transmitted by the strong influence of peer groups (Valdemoros, Sanz, & Ponce, 2012). Conclusions Schools and society must promote women's equality sports. We must be careful with sexist offensive messages, especially among students and peer groups, both boys and girls. References Bericat, E. (1998). THE POTENTIAL OF OUTDOOR EDUCATION ACTIVITIES FOR PROMOTING GIRLS' MOBILITY IN PUBLIC SPACE

KNECHTL, S., GIESS-STUEBER, P.

University of Freiburg, Institute of Sport Science

Introduction It is a major educational objective to support children and adolescents in their development, particularly when it comes to the participation in cultural, public, social as well as sportive concerns (Report on Children and Youth, 2013). Especially girls living in segregated and deprived areas are disadvantaged as they lack in access to public sporting areas and sport clubs (Brandl-Bredenbeck et al., 2015). Urban social spaces enable experiences of places, PA, and encounters with the unknown (Graumann, 2002). The main aim of an outdoor education project was to encourage girls to interact with their social, cultural and public surroundings. By encountering their vicinities they learned how to participate and appropriate public space via PA. The development of social competences and also motor

skills were central. Methods Questionnaires were provided for girls from three schools ($N=27$, 7-14ys) after every workshops (t1/t2/t3) and 10 weeks after the project (t4). Additionally observation protocols were kept. A year after the project group interviews ($N=4$) were conducted to evaluate possible changes in mobility and activity behavior. In the last step all data was intermingled. Results Results show that the family and peers are important for an active lifestyle, but environmental factors and perception of surroundings seem not to influence active space appropriation. Although the girls criticize their surroundings they don't leave their nearby areas and don't use their broadened social networks. As it appears guided extracurricular activities and the trainer are of pivotal importance for increasing active mobility. Discussion The findings highlight the great potential of experiential education in the course of extracurricular activity programs for enabling girls to become acquainted with their environments and expanding their social networks and skills. In order to promote sustainable active mobility an increased awareness of the individual lifeworlds (Spatscheck et al., 2009) is crucial. The predominant close relationships between the girls and the trainers appear to be of high significance for enabling girls to participate in and actively appropriate public space. HEALTH BEHAVIOUR OF 10-14 YEAR OLD STUDENTS IN THE PERIOD FOLLOWING THE INTRODUCTION OF EVERYDAY PHYSICAL EDUCATION

FINTOR, G.

University of Debrecen, Doctoral School Of Humanities

Introduction Physical education is a compulsory school subject in all member states, it plays an important role in establishing and maintaining physical and mental balance of health, and it also has key role in the education of healthy lifestyle. Hungary had outstanding results in the proportion of physical education lessons per week in the European Union even before (!) the introduction of everyday physical education (Eurydice Report 2013). However, problems are apparent: taking international researches in consideration, (Strong et al 2005) Hungarian youth do not exercise enough (Perényi 2014), the physical activity of that particular age group is not sufficient regarding their health (Barabás-Nagy 2012). A good number of international researches point to the fact that doing sports regularly (that is, every day) has beneficial effects on health and also on the formation of youth's health awareness (Shephard 2013). In Hungary the everyday physical education lessons were introduced in September 2012, one of the most important main reasons of which was to help the students change their health behaviour and willingness to do sports, in a long term period, and help these changes to be durable as an effect of physical education lessons (NAT 2012, Mikulán 2013). The theoretical bases of our study are the implementational researches (Halász-Fazekas 2012) and the close examination of questions regarding curricular theory (Hamár-Ladislav 2008, Hardman-Marshall 2009, Rétsági 2014). Methods Data collection was conducted in Nyíregyháza ($n=285$), in May 2014 in four schools, with the help self-completion questionnaires. We were also interested in what kind of harmful behaviour examples can be found within the age group of 10-14 year old youth. Furthermore, aligning our research to the aims of NAT 2012 we sought answer to the question: what kind of values do the positive and negative attitudes regarding everyday physical education have among the students. We have also discussed the differences between gender and grades; we have employed factor analysis besides crosstable reference and frequency analysis. Results When we examine the gender differences in statements in connection with the everyday physical education, higher values appear with results outside school lessons and the affection towards physical activity and exercise for the boys, and doing less sports and being tired for the girls. According to our results, boys and students in general in higher grades consume more alcohol than others. Discussion The importance of our research is highlighted by the fact that the health status of the future generations are essentially important regarding both economical and financial questions and the competitiveness of the country. The everyday physical education lessons may add to this goal with their aims set; our research is also a contribution to this large research.

EFFECTS OF AN OUTDOOR PARKOUR TRAINING SESSION TO THE EXPECTATIONS FOR AN UPCOMING INDOOR TRAINING SESSION – A QUALITATIVE INTERVIEW STUDY WITH YOUNG TRACERS

KORTHAUER, M., WIESCHE, D., KIRMSE, M.

Ruhr-Universität Bochum

Introduction: Parkour is a way of training, which allows us to confront obstacles. Expectations take an important part in training and performing Parkour. Tracers (Athletes of Parkour) can practice in urban terrain or in a gym. Preceding outdoor training sessions appear to have an impact on the expectations for upcoming indoor practices. This research displays the effects of self-efficacy experiences (outdoors) on the training expectations of young Tracers. Methods: 3 male Tracers (15, 17 and 18 years; at least 18 months Parkour training experience inside the gym/ no experience outdoor) participated in this study. Interviews were made right before a usual indoor Parkour training session. The intervention contained a common outdoor practice with other experienced Tracers. Right before the next indoor lesson a second interview session was conducted. These methodic interviews emphasized the prospects and the perceived self-efficacy. Transcriptions were made and the responses were ranked in a quaternary system. The categories were stepwise refined. The peculiarities (1 = low-response up to 4 = high-response) of the two interview sessions were listed and compared. Subsequently the Results were discussed on the basis of selected quotes of the transcriptions. Results: The interviews showed many differences in the ranking: All participants specified their personal main goal in the sport (+1, +1, +1). They mainly planned more innovative exercises (+3, 0, +1). One of them had an even better connection to his main goal (+2, 0, 0). Another one got much more autonomy and was able to point out a specific moment of perceived self-efficacy (0, 0, +2; 0, 0, +1). The participants became aware of their own strengths and weaknesses (+1, +1, 0) and increased their aim to confront it (+1, +2, +1). The only aspect that was decreased was the specificity of the target for the day (0, -1, -1). Discussion: The Subjects showed positive changes in all categories, except the concreteness of the day's target. The Tracers explained this decrease with their lack of experience in the new exercises, they planned to face now. The interviews showed an enhanced confidence and motivation for the following training session and their future in the sport. The self-efficacy experience showed a definite impact on the expectations to the following training. Caused by a low number of subjects the research cannot claim generality. However, it can be indicatory for further studies or training schedules in this new and mostly uninvestigated sport. Contact: marius.korthauer@rub.de

EXAMINATION OF SELF-DETERMINATION WITHIN THE TEACHING PERSONAL AND SOCIAL RESPONSIBILITY MODEL IN PHYSICAL EDUCATION

HSU, W., PAN, Y.

Fo Guang University

Introduction The current trend of physical education has turned to the emphasis on holistic development of students. The teaching personal and social responsibility (TPSR) proposed by Hellison (2011) is one of the most iconic models under this context. However, previous studies were still unable to identify the mechanisms of students' responsibility development. Based on the self-determination theory (SDT), different types of motivations are influenced by social factors through satisfying three basic psychological needs – competence, autonomy, and relatedness. (Deci & Ryan, 2002). The social factor described in SDT is conceptually in line with the positive learning environment emphasized by TPSR. Therefore, the study aims to examine whether students satisfied on autonomy, relatedness, and competence in TPSR. It is expected to identify the reason why TPSR can produce positive outcomes and further develop the strategies to enhance the TPSR implementation. **Methods** The participants were high school students in Taiwan. The experimental group (38 students) was the class participating in TPSR-implemented physical education while control group (36 students) received regular PE classes without any intervention. Pre-test was made on the first week and post-test was made on the 18th week. The actual experimental duration was 16 weeks. The measurement for both pre-test and post-test was the BPN-PE. Results MACOVA showed the main effect was significant (Wilks' $\Lambda = .673$, $F(3, 67) = 10.85$, $p < .05$, $\eta^2 = .33$). The between-subject effects suggested significant results in autonomy ($F(1, 73) = 10.53$, $p < .05$, $\eta^2 = .13$) and relatedness ($F(1, 73) = 23.81$, $p < .05$, $\eta^2 = .26$) but not in competence ($F(1, 73) = 1.72$, $p > .05$, $\eta^2 = .03$). The results indicated the scores of experimental group were significantly higher on autonomy and relatedness than control group while there was no significant difference on competence. **Discussion** TPSR focused on the establishment of interpersonal relations between teacher and students as well as peers. The model also granted student with the power of decision making and allow them to have sufficient autonomy. Therefore, students in TPSR showed higher satisfaction on relatedness and autonomy. Nonetheless, no connection to competence was found in the framework of TPSR. Therefore, the effects of TPSR on the responsibility development may be generated by advance the satisfaction on autonomy and relatedness. Owing to the absence of competence support in the framework of TPSR, we suggest that the strategies of competence support could be integrated into TPSR. **References** Deci, E. L., & Ryan, R. M. (2002). Handbook of self-determination research. Rochester, NY: University of Rochester. Hellison, D. (2011). Teaching responsibility through physical activity. Champaign, IL: Human Kinetics.

A FOCUS GROUP STUDY OF PE TEACHERS' CONFLICT MANAGEMENT STRATEGIES

NÉMETH, ZS.

University of Pécs, Institute of Sport Science and Physical Education

Introduction Physical education teachers are faced with a lot of conflicts during their work. This is natural, because interpersonal relationships already contain the conflicts (Coleman et al., 2014). If these conflicts get on surface, PE teachers try to solve them in a variety of ways. In my opinion, the quality of the management of conflicts is strongly influenced by the teaching-learning process efficiency, so we need a deeper analysis of the most common conflicts. **Methods** I conducted a focus group study with seven physical education teachers of different ages and different types of schools (Krueger and Casey 2009; Liamputpong, 2011). Among the participants there were men and women who were at the beginning, the middle and the end of their career of physical education teaching. The questions referred to the different types of physical education classes and the most common places, causes and conflict-resolving methods during different competitions. **Results** The findings of the study were that conflict management strategies were influenced mostly by the situations, the students' communication style, the type of physical education lessons and the age characteristics of the age groups. Such exercises should be differentially planned for the skill-developing lessons during the implementation of which all participants can experience a sense of achievement (Shimon, 2011). Physical education teachers need to create an atmosphere that reduces the probability of conflicts to the minimum. The personal example of physical education teachers may improve the situation. **Discussion** The aim of my lecture is to call attention to the factors which can influence the PE teachers' attitude in teaching-learning process efficiency. By this research I would like to help my PE teacher colleagues to develop effective conflict management. It turned out, that in order to achieve effective conflict management we need the following abilities: self-knowledge, selfcontrol, empathy, the communication style fitting the situation and tolerance. **References** Coleman Peter T. – Deutch Morton – Marcus Eric C. ROMA AND NON-ROMA CHILDREN'S MOTOR SKILLS

SERBETAR, I., LOFTESNES, J.M., PRPROVIC, I.

Faculty of Teacher Education Zagreb, Croatia; HISF Sogndal, Norway

ROMA AND NON-ROMA CHILDREN'S MOTOR SKILLS The Roma children have traditionally been disadvantaged in many cultures (Semoglou et al., 2008; Walls, 2013). Poverty and common social exclusion of that ethnic group largely determine child's academic success, moreover school deprivation and residential segregation could also cause underdevelopment of motor skills and related intercultural differences in overall motor performance. That was partially confirmed in the study by Semoglou et al. (2008), which found that Greek-Roma preschool children significantly underachieved in visual motor integration, but not in the gross motor skills. In another Greek study, Tsimaras et al. (2011) reported that Greek-Roma children (7-10 yrs) performed significantly poorer in locomotion skills, handling skills and general motor ability. Similarly, Zsidegh et al. (2007) found on a sample of Hungarian-Roma boys (7-14 yrs) that they were significantly inferior in running. The aim of the present study was to evaluate possible differences in motor skills among Roma and non-Roma children in Croatia. Convenient sample of 114 children (57 Roma children) aged 10, who attended two primary school's in northern Croatia, were assessed using MABC-2 (Henderson et al., 2007). According to percentile norms of the test, 4 children fall in the category of "motor impairment" while another 5 fall in the "risk for impairment", and 7 of them were Roma minority. To test the differences in motor skills, a MANOVA 2 (gender) x 2 (ethnicity) was applied with 3 component standardized scores (manual dexterity, aiming and catching and balance) and total standard score as dependent variables. MANOVA showed significant gender (Wilks' $\Lambda = .729$, $F(4,107) = 9.956$, $p = .000$, part. eta sq. = .271) and ethnicity (Wilks' $\Lambda = .754$, $F(4,107) = 8.729$, $p = .000$, part. eta sq. = .246) effects. Subsequent univariate analysis showed that the girls were better in manual dexterity $F(1,110) = 15.350$, $p = .000$, part. eta sq. = .122 while the boys outperformed girls in aiming and

catching $F(1,110)=12.935$, $p=.000$, part. eta sq.=.105. Also, non-Roma children were better than Roma children in manual dexterity $F(1,110) = 23.840$, $p=.000$, part. eta sq. = .178; balance $F(1,110)=16.565$, $p=.000$, part. eta sq.=.131; and total test score $F(1,110) = 25.610$, $p=.000$, part. eta sq.=.189. The MANOVA also yielded gender x ethnicity interaction effect (Wilks' L=.910, $F(4,107)=2.642$, $p=.038$, part. eta sq.=.09) but the only significant univariate difference was found in aiming and catching favoring non-Roma boys. The current study shows delayed development of the motor skill's in Roma children. The probable cause are different social and environmental factors but also (im)possibilities for learning and practice. References Henderson, S. E., Sugden, D. A., Barnett, A. L. (2007). PRACTICING CONSIDERATION ABOUT NOGUCHI TAIKO; CASE STUDY IN A WORKSHOP OF FEMALE COLLEGE STUDENTS

HATANO, Y., OTAKE, R.

Kobe Shinwa Women's University

Introduction Dance has become increasingly important in the curricula within Japanese physical education in schools along with growing popularity of dance in modern society. Despite the rapid expansion of educational opportunities for dance, most students seem to have technical difficulties in maintaining a balance between tenseness and relaxation of their muscles during the physical movements of a dance performance. In the present study, the authors focused on techniques for muscle relaxation rather than muscle tension to improve movement skills, and examined the effectiveness of the Noguchi Method, a teaching method for physical education emphasizing relaxation, when teaching dance in a workshop for female university students. Methods The philosophy and details of the Noguchi Method were explored through an examination of written sources. The study also examined the ethnographic aspects, of teaching the Noguchi Method, taught by one of the successors of the Noguchi Method, in a workshop for eight female university students. Results Noguchi Method, which is referred to as "Noguchi Taiso" in Japanese, was established by Michizo Noguchi, as a method of physical exercise in Japan. The concepts of the movements of Noguchi Taiso are characterized as the most economical way to move, and reliance on the weight of the body. The most famous book on the Noguchi Taiso was written by Misao Hatori. Also several Butoh dancers discuss the method as a techniques of contemporary dances on the Web-site of Noguchi Taiso. The workshop students were asked to write their opinions of the workshop. They were categorised based on the KJ method, as 'discovery of their own body', 'the function of Nogu Discussion The students felt how to use their bodies to generate relaxation and power, in ways different from usual movements. At the practitioner's workshop, it was possible to remove muscle movements and power in ways that differed from the usual techniques. It is thought that the Noguchi Method is effective for not only the body but also mind for students in dance education. COORDINATION BETWEEN RACKET AND BALL: AGE EFFECT ON INFORMATION STRATEGY IN TABLE TENNIS SERVICE

CHUANG, K.L.1, LIU, Y.T.2

National Taiwan Normal University

Introduction Table tennis is a sport of interceptive actions. The coordination between the ball and racket, or timing performance, plays paramount importance in executing the interceptive actions in table tennis. The affordance of the environment reflects the coupling relations between an individual and the environment, which may be considered as an information strategy that is adopted by the individual to guide the skill development. When performing the same interceptive action, table tennis players of different developmental stages may use different information strategies due to their different experience and growth factors. The fast deep flat service is one of the most fundamental yet important table tennis skills that should be mastered in the early stages of training. The purpose of the study was to examine the different information strategies used by children and adult table tennis players when performing the fast deep flat services. Methods 8 male collegiate table tennis club players (19-22 yrs), and 8 boys (9-10 yrs) from the table tennis team of an elementary school participated in the study. Participants were asked to aim for a 30x30 cm² target area and performed 20 fast deep flat services. 2 high-speed cameras and the Kwon 3D digitizing system were used to capture the kinematics of the ball and racket. Independent sample t-tests were used to compare the service and timing performances of two groups. Pearson product-moment correlations were calculated to examine the various relations of the timing measures for each group. Results There were no significant differences for the service performances measured in the rate of hit, racket velocity at ball-bat contact, and the maximal forward velocity of the racket between the 2 age groups. However, children had significantly more variability in the performance of movement initiation than adults. In addition, children also showed a significantly higher coefficient of correlation between the racket velocity and the distance to the ball-bat contact at the start of forward acceleration phase. Discussion It was expected that there would be no difference in the service performance between the 2 groups because both groups of participants had been trained in table tennis for about 2 years. However, the differences of the various timing performance measures between the age groups reflected the different information strategies adopted by different age groups as a result of the difference in their developmental stages. Although children had more variability in the movement initiation, they were able to successfully carry out the service performance with the tight coupling between these movement initiation parameters. Adults, on the other hand, were able to use the information of the ball to control the movement initiation and showed a more stable timing performance than children. Future studies will examine table tennis players of different skill levels in order to explore the relation between timing performance and skill level.

DUAL-TASK PERFORMANCE DIFFERS BETWEEN STAIRCASE ASCENT AND DESCENT IN YOUNG ADULTS

GAILLARDIN, F., BAUDRY, S.

Université libre de Bruxelles

Introduction Staircase negotiation is among the most challenging locomotor activities, with staircase descent being reported as the most hazardous aspect of staircase negotiation. Previous work has reported that a cognitive task performed while stepping upstairs (2) and downstairs (3) altered the kinetics of staircase negotiation, but no study has compared the dual-task performance between ascent and descent. Furthermore, reporting the pattern of change only in the motor task cannot account of the trade-off for performance between motor and cognitive tasks. The purpose of the present study was to compare the influence of dual-tasking between stepping upstairs and downstairs in young adults. Methods Ten young adults stepped up and down a 3-step staircase equipped with force platforms in two conditions: 1/ without concurrent cognitive task (single motor task); 2/ while recalling a list of words provided prior to staircase negotiation (dual-task). The cognitive task was also performed in a seated position (single cognitive task). Performance in motor and cognitive tasks was measured as the duration of the ascent or descent, and the number of words recalled, respectively. Motor and cognitive dual-task costs (DTC) were calculated as follows: (dual task performance – single task performance)/100/single task performance. The combined DTC was calculated as follows: (cognitive DTC + motor DTC)/2 [4]. Results The duration of staircase negotiation was greater in dual- than single-task condition ($p=0.002$). Motor DTC was greater during staircase descent (+34.2±26.4%) than ascent (+15.0±21.5%; $p=0.004$). In contrast, the cognitive score did not differ between single- and dual-task conditions ($p=0.077$), with no difference in cognitive DTC between staircase descent (-4.0±11.0%) and ascent (-9.9±13.8%; $p=0.29$). The combined DTC was greater when stepping downstairs (+19.1±16.6%) than upstairs (+12.4±13.4%; $p=0.035$). Discussion This study is the first to compare DTC between staircase ascent and descent. The results indicate that the combined DTC was greater during staircase descent than ascent, mainly due to the greater motor DTC during descent. This may rely on the greater biomechanical constraints of staircase descent [1], which may reduce the ability to share adequately the attentional resources. These results can have relevant implications for our understanding of the greater risk of falls in staircase descent. References 1. Revees et al. (2008). J Exp Biol 19:57-68 2. Vallabhahosula et al. SUCCESSFUL NATIONAL SAILORS EXHIBIT BETTER VISUAL SEARCH STRATEGIES DURING A RADIO CONTROLLED SIMULATED EVENT

WALKER, C., WELMAN, K.

Stellenbosch University

The aim of the present research was to investigate the visual search strategies of South African sailors during a radio controlled simulated race. Twenty-two sailors completed three radio controlled match races while wearing a mobile eye tracker (ASL Mobile Eye). Races lasted an average of 197.51 (s = 40.05) seconds. Assessed variables included the race performance, the search rate (total fixations, average fixation duration, frequency) and the percentage viewing time. Sailors were grouped according to professional sailing history rank, success rate in the simulation and their respective sailing classes. The results revealed that the top ranking group performed 13.9% fewer fixations per second compared to the bottom ranking group ($p = 0.03$). In terms of success rate, the successful group exhibited a more efficient visual search strategy consisting of fewer fixations ($p = 0.01$) of longer duration ($p = 0.34$). The dinghy class differs between the keelboat class ($p = 0.02$) and the multihull class in the percentage viewing time to the BOAT HULL location. This suggests that these sailors identified this location as a more valuable source of information.

DOES VISUAL SEARCH STRATEGY CHANGE DURING SOCCER PENALTY KICKS TAKEN WITH THE DOMINANT VS. NON-DOMINANT FOOT?

BAKER, J., SCRUTON, A., VAN PARIDON, K., TIMMIS, M.A.

Anglia Ruskin University

Introduction- When taking a soccer penalty kick, research has shown that a number of factors impact a player's visual search strategy. To date, there is no research investigating whether the visual search strategy during penalty kicks changes when comparing the dominant against the non-dominant foot. This was the focus of the present study. Methods- 10 soccer players were recruited and took two penalty kicks with the dominant and non-dominant foot. The study took place indoors in accordance to The Football Association (F.A.) guidelines for indoor football. A goalkeeper stood in the centre of a goal measuring 3.66m wide by 1.83m high. A football was placed 6 metres from the centre of the goal. Eye movements of the penalty takers were recorded using SMI Eye tracking glasses. Peak horizontal velocity and resultant velocity for both the dominant and non-dominant foot were recorded along with the end location of the football. Results- The football was kicked with significantly greater velocity with the dominant compared to the non-dominant foot ($m=14.3\pm1.4m.s^{-1}$, $11.6\pm1.5m.s^{-1}$ respectively, $p=.005$). Furthermore, the ball was kicked significantly wider towards the edge of the goal in the dominant compared to non-dominant foot / penalty ($p=.002$). The overall duration of the penalty was significantly longer in the non-dominant compared to the dominant penalty ($m=5.20s \pm 1.16$, $4.53s \pm 0.76$, respectively $p=.013$). When executing the penalty with the dominant foot, players showed a trend of longer relative fixation length towards the edge of the goal compared to the non-dominant foot ($p=.052$). Relative fixation length was significantly shorter on the ball ($p=.004$) with fewer relative number of fixations on the ball in the dominant compared to non-dominant foot ($p=.004$). In the dominant penalty, players has longer fixation in the 'gap' between ball and goal compared to the non-dominant penalty ($p = .030$). Discussion/conclusion-Results highlight a difference between visual search strategies when executing a penalty with the dominant compared to non-dominant foot. With the dominant penalty, players fixated and kicked wider within the goal compared to the non-dominant penalty. Penalties executed with the non-dominant foot took significantly longer to complete with greater frequency and length of fixation on the ball. Interestingly, with the dominant foot, players fixated the gap between the ball and goal, appearing to utilise peripheral vision to guide the approach to the ball. These findings suggest an association of increased skill mastery on the dominant foot. Further work should address this association in professional players.

IS VISUAL SEARCH STRATEGY DIFFERENT BETWEEN SCORED AND SAVED PENALTY KICKS FROM THE SAME SOCCER PLAYER?

TIMMIS, M.A., VAN PARIDON, K.N.

Anglia Ruskin University

Introduction- The visual search strategies employed by soccer players when executing the penalty kick has received widespread research interest. To date, there is no research investigating the differences between visual search strategies in consecutive penalties which are scored and saved by the same soccer player. This was the focus of the present study. **Methods-** 30 amateur soccer players were recruited and took 2 placement penalty kicks, indoors, according to The Football Association (F.A.) guidelines for indoor football. The placement penalty required players to kick the football accurately to a corner of the goal. Eye movements of the penalty taker were recorded using SMI Eye tracking glasses. End location of the football was also recorded. Only those players who both scored and had their penalty saved by the goalkeeper (either order) were retained for analysis; 12 players met this criteria. **Results-** Saved penalties were kicked significantly more centrally in the goal ($p < .001$). This was a result of increased length of time ($p = .002$) and frequency ($p = .011$) spent fixating to the goalkeeper in the approach phase prior to taking the penalty. This subsequently resulted in reduced fixation time on the ball ($p < .001$). In the final steps of the approach, immediately prior to kicking the ball, players who had their penalty saved increased length of time spent fixating on the area immediately ahead of the ball ($p = .005$) and initially fixated to this area earlier in the approach ($p = .025$). The earlier fixation on the area immediately ahead of the ball in the saved penalty resulted in players having reduced quiet eye (QE) period ($p = .03$) which ended earlier prior to kicking the ball ($p = .008$). **Discussion/conclusion-** The current study found that saved penalties were the result of the penalty taker kicking the ball more centrally in the goal i.e. closer to the goalkeeper. This effect may be attributed to the distracting effect of the goalkeeper (despite standardising goalkeeper instructions; Wood and Wilson, 2010). During the saved penalty, in the final approach to the ball, players disengaged (fixated away) from the ball earlier prior to kicking the ball. Shorter QE periods, which also end earlier prior to the end of the action have been identified as a cause of task failure. Fixating away from the ball and making a predictive saccade in anticipation of tracking the ball after being kicked (c.f. Mann et al., 2013) may have impacted the quality of foot-ball contact, subsequently affecting kicking accuracy. Mann, DL. Spratford, W. Abernethy, B. 2013. doi: 10.1371/journal.pone.0058289 Wood, G. Wilson, MR. 2010. doi: 10.1080/02640414.2010.495995.

DEVELOPMENT AND VALIDATION OF A PROXY FOR GAZE BEHAVIOUR MEASUREMENT IN FOOTBALL.

OPPICI, L.1, PANCHUK, D.1,2, SERPIELLO, F.R.1, FARROW, D.1,2

Victoria University

Affiliation: 1: Institute of Sport, Exercise and Active Living (ISEAL), Victoria University, Melbourne, Australia. 2: Australian Institute of Sport (AIS) **Introduction:** Wearable, head-mounted eye trackers are widely used in sport-psychology research to assess eye movements and provide insights into perceptual-cognitive changes underpinning the development of sport skill. Where possible, the assessment of eye movements should take place in the performer's natural environment as decision making and attentional processes are constrained by the environmental cues the performer is responding to. However, quick head movements and ground impact in dynamic tasks, such as football games, affect the reliability in detecting eye features, limiting the evaluation of gaze location. We developed a new approach to deal with this issue and validated a method that uses head orientation as a proxy for gaze measurement in football. A window, using gaze coordinates, was designed to derive the gaze location in the absence of point-of-gaze references and validated against the gold standard point-of-gaze method. **Methods:** Forty-eight youth football players performed 6 v 6, small-sided games on a modified pitch. The raw gaze coordinates on the x- and y-axes of 6 players were plotted to analyse the dispersion of gaze. Two standard deviations from the mean were used to capture the majority of gaze behaviour (95.44%) and in turn develop an empirical coding window to classify the gaze in two gaze regions of interest, described as player-directed or ball/ground-directed. To validate the new method, footage collected from the eye tracker of 12 players were coded frame-by-frame using the empirical window and compared to the standard point-of-gaze coding. **Results:** The overall agreement between the two methods was 90%. However, this rate of agreement does not account for the agreement expected by chance. Cohen's kappa value, which corrects for this, was 0.64 ($p < 0.001$). Furthermore, the distribution of the categories in the data was skewed as 2830 belonged to one category and 597 belonged to the other. The kappa value was influenced by this prevalence issue and the adjusted-kappa (PABAK) was 0.80, indicating substantial agreement between the two methods. **Discussion:** Locomotor activities, in general, create noise in gaze data and this new coding method, using a window derived from gaze location coordinates, is a valid approach to overcome potential issues when assessing eye movements in dynamic tasks, such as football small-sided games. Researchers operating in the field may use this approach when dealing with poor quality data and it may encourage researchers to perform their experiments in participant's natural environments. RELATIONSHIP BETWEEN FUNDAMENTAL MOVEMENT SKILL COMPETENCE AND BEHAVIORAL MOVEMENT PATTERNS DURING FREE PLAY IN PRESCHOOL CHILDREN

SASAKI, R., ISHIZAWA, J.

Keio University

Introduction Children with greater access to physical activity may have more opportunities to develop their fundamental movement skills (FMS); in contrast, children with limited access may have correspondingly fewer opportunities (Gallahue et al, 2012). It would be important to provide children with many opportunities to experience various physical movement patterns in early childhood. In the present study, we compared behavioral movement patterns among children with and those without sufficient FMS competence during free play activities to determine what support preschool children may require in FMS acquisition. **Methods** Participants were typically developing children (both boys and girls) aged 5–6 years. We made video recordings of participants during a free play period in their kindergarten for 30 minutes consecutively. From this video footage, we observed and categorized children's movements in terms of moment-to-moment changes in all behaviors (e.g., "walk," "run," "sit/squat," "throw," "kick"). Then, we analyzed the numbers of occurrence of movement, the frequency that it occurred on a minute-by-minute basis, and the time duration of each movement. We then compared the behavioral patterns of children according to their FMS competence. **Results** We observed more movement categories among children with higher FMS competence than among children with lower competence. Furthermore, children with higher FMS competence tended to engage in each movement more frequently per minute and for longer than did children with lower FMS, particularly at the beginning of the observation period. Sedentary behavior was more frequently observed among children with lower FMS competence, particularly among girls. Among children with higher FMS competence, we observed whole body movements and multiple movements more frequently. **Discussion**

sion The results indicated that children with higher FMS competence tended to have longer and more varied and complex behavior patterns (e.g., multiple simultaneous movements). Although children with lower FMS competence did engage in locomotion, their movements were rather simple (e.g., walking and running) and less varied during free play activities. Previous research has indicated that greater motor competence promotes higher levels of physical activity, which in turn gives children more opportunities to enhance their FMS competence (Gallahue et al., 2012). Notably, we observed gender differences in sedentary behaviors, with them occurring more frequently among girls than among boys. In a previous study, it was suggested that improving FMS competence can potentially lead to more physical activity and less sedentary time among children (Capio et al., 2015). Based on our findings, we must point out that there is a need to provide organized opportunities that facilitate children's acquisition of FMS, which may include teaching unfamiliar movements, usage of play equipment, and providing appropriate spaces. A SYSTEMATIC REVIEW OF GAIT PERTURBATION PARADIGMS FOR IMPROVING REACTIVE STEPPING RESPONSES DURING WALKING AND REDUCING FALLS IN OLDER PEOPLE

MCCRUM, C.1,2, GERARDS, M.1, KARAMANIDIS, K.2, ZIJLSTRA, W.2, MEIJER, K.1

1: Maastricht University, The Netherlands. 2: German Sport University Cologne, Germany.

Introduction Falls in older people most often occur due to trips or slips during walking (Berg et al. 1997). Consequently, there is a need to prepare older adults to cope with unexpected mechanical disturbances to gait. As involuntary, compared to voluntary, stepping responses to perturbations are faster (Luchies et al. 1999), unexpected gait perturbations may be the most task-specific stimulus (Oddsson et al. 2007). Therefore, we systematically searched for studies that applied unexpected mechanical disturbances to walking in older adults, in order to determine which characteristics of such paradigms can improve reactive stepping responses during walking and reduce falls in older people. **Methods** A systematic search of PubMed, Web of Science, MEDLINE and CINAHL databases was conducted with sets of terms relating to gait, perturbations, adaptation and ageing. Inclusion criteria were that the studies were conducted with healthy participants with a mean age of 60 years or older, that the studies applied repeated mechanical perturbations of an unpredictable nature during walking, and that reactive stepping responses to gait perturbations or numbers of laboratory or daily life falls were recorded. **Results** The search yielded 3332 unique results. After title, abstract and full text screening, 10 studies met the inclusion criteria, with two using the same experiment. In these studies, moveable floor platforms ($n=5$), ground surface compliance changes ($n=2$) and treadmill belt accelerations or decelerations ($n=3$) were used to perturb gait in older people. Single sessions of 5 ($n=1$), 16 ($n=1$), 20 ($n=1$) and 24 ($n=4$) perturbations led to improved reactive stepping responses to perturbations, with one study showing transfer to another perturbation task. Two studies did not report the number of perturbations used. One study reported retention and a 50% reduction in daily life falls over the 12 months post-session. One study assessed the influence of additional sessions, reporting improved retention at six months, when an additional single perturbation was experienced three months post-session. **Conclusion** Single sessions of repeated gait perturbations can improve the reactive stepping responses of healthy older adults. Two studies have found that adaptations can be retained, but this requires further investigation, as it is unclear how perturbation magnitude, variability, frequency, number and type affect retention or falls incidence after undergoing perturbation sessions. IS-PM06 HIT training - Mechanisms and applicability

HIT TRAINING - MECHANISMS OF ADAPTATION

GIBALA, M.

McMaster University

Interval exercise refers to the basic pattern of alternating periods of more intense effort with period of less intense effort, or complete rest, within a single training session. Owing to the wide variety of terms used to describe this basic type of exercise, a classification scheme was recently proposed to delineate "high intensity interval training" (HIIT) from "sprint interval training" (SIT) (1). HIIT generally refers to submaximal exercise protocols in which the workload elicits a relative intensity corresponding to $\geq 80\%$ of peak heart rate. SIT describes protocols in which the intensity corresponds to $\geq 100\%$ of the workload that elicits maximal oxygen uptake (VO_{2max}). Dating back several decades, numerous studies have examined physiological adaptations to HIIT and traditional moderate-intensity continuous training (MICT), matched for total work or energy expenditure. While these have yielded equivocal results, several recent systematic reviews and meta-analyses have concluded that HIIT elicits superior physiological adaptations in both average healthy individuals and people with lifestyle-induced cardiometabolic disease (1-3). Research over the last decade in particular has shed new light on the potency of low-volume interval training, which involves a relatively small total amount of exercise, to elicit physiological adaptations that are comparable to MICT in a time-efficient manner (4). Studies that have directly compared MICT to low-volume HIIT or SIT protocols have reported similar improvements in markers of aerobic energy metabolism, as well as clinical indices of health status, despite large differences in total exercise and training time commitment. Recent evidence supports the general contention that exercise intensity is more important than duration for exercise training-induced increases in cardiorespiratory fitness (5). In contrast, the specific roles of intensity, duration and volume on aspects of exercise-induced skeletal muscle remodelling, in particular mitochondrial biogenesis, are equivocal (6). Recent work suggests the potential for SIT to promote greater and faster mitochondrial adaptations in human skeletal muscle than does HIIT or MICT despite a much lower training volume (7). It was also reported in humans that muscle fibre-type specific responses to SIT were strikingly similar to MICT despite lower training volume (8). (1) Weston KS, et al. HIT TRAINING IN HEART PATIENTS - DOES IT WORK?

PRESSLER, A.

Technical University Munich

Twenty years ago chronic heart failure was considered a contraindication for regular physical activity. Many believed to be counterproductive to recovery and perhaps harmful to chronic heart failure patients. However, in recent years numerous studies have proven the feasibility and safety of exercise training in heart failure patients. Exercise now plays a pivotal role in the treatment of systolic heart failure in addition to medical or device-related therapy. Regular exercise has been shown to increase exercise capacity and quality of life, as well as reduce symptoms and lower hospitalization rates. It also has the potential to increase left ventricular ejection fraction and reduce mortality. However, the dose of exercise to induce these effects is still uncertain. During recent years high-intensity exercise has been investigated in heart failure patients. These data reveal superior effects than with moderate training, however, large data sets are scarce and optimal medical therapy has to be assured. Including HIT into the regular treatment of patients with heart failure needs a detailed medical examination and a tailored exercise program including also other modes of exercise as moderate intensity endurance and resistance exercise.ö

HIGH INTENSITY INTERVAL TRAINING AS A CURE FOR TYPE 2 DIABETES?

DELA, F.

University of Copenhagen

Type 2 diabetes is characterized by a combination of insulin resistance, insufficient insulin secretory capacity and genetic disposition combined with excess energy intake and physical. Physical training alleviates insulin resistance, may improve insulin secretory capacity and improves glycemic control in patients with type 2 diabetes. Large clinical studies lifestyle interventions including weight loss and increased physical activity have shown fewer hospitalizations, fewer medications, and lower health-care costs, but on specific cardiovascular endpoints the results have been disappointing in large scale studies. Thus, while there is no question about the effectiveness of physical training as medicine for insulin resistance, the major problem is that the patients do not take the medicine. There are many barriers to overcome and motivation, safe environments, convenience and lack of time are considered to be among the major reasons for not exercising on a regular basis. High intensity interval training (HIIT) with short periods of intense exercise interspersed with brief periods of rest is a time efficient exercise modality which might surpass some of the barriers. As with almost any kind of exercise, an acute high intensity training bout will lower glucose concentrations in patients with type 2 diabetes. However, the longer term (training for 2 weeks or more) studies that have been conducted in patients with type 2 diabetes have generally used insufficient methods for determining the effect of HIIT on insulin secretion and sensitivity, which are the key parameters in the pathophysiology of type 2 diabetes. Hence, by using measurements of interstitial glucose concentrations, HOMA or HbA1c, either marginal or no effect and significant effects of HIIT on glucose homeostasis have been reported. None of the previous studies have used the gold standard for assessment of insulin sensitivity, the glucose clamp technique and none have studied specifically skeletal muscle, which the tissue that takes up the vast majority of glucose during insulin stimulation. Previous studies have addressed the molecular effects of high intensity interval training in skeletal muscle but only one study in patients with type 2 diabetes. In general these studies shows that HIIT leads to increases in proteins (activity and/or content) related to mitochondrial biogenesis, such as citrate synthase (CS), complexes in the mitochondrial respiratory chain, silent mating-type information regulator 2 homolog 1 (SIRT1), peroxisome proliferator-activated receptor γ coactivator-1α (PGC-1α), mitofusin (Mfn)-2. Also skeletal muscle GLUT4 protein and glycogen content seem to increase with HIIT, and furthermore, an increased capacity to fat oxidation (less exercise induced decrease in glycogen and increased hydroxyl-acyl-dehydrogenase (HAD) activity) takes place after HIIT.

Invited symposia**IS-PM07 Mitochondrial function and adaptation to stressors****EFFECTS OF HIGH INTENSITY TRAINING ON MITOCHONDRIAL FUNCTION IN SUBCUTANEOUS ADIPOSE TISSUE AND SKELETAL MUSCLE**

LARSEN, S.

University of Copenhagen

In the last couple of years high intensity training (HIT) has again been studied intensively. HIT has been shown to increase maximal oxygen uptake ($\text{VO}_{2\text{max}}$) and skeletal muscle mitochondrial oxidative phosphorylation (OXPHOS) capacity in young male subjects. Furthermore it has also been reported that HIT improves glucose tolerance in young subjects, this effect could potentially be via a reduction in reactive oxygen species (ROS) production from the skeletal muscle, but this has never been investigated after HIT before. The literature is sparse, when it comes to HIT in older females and males. Furthermore mitochondrial respiratory capacity has not been investigated after HIT in subcutaneous adipose tissue previously. During the talk it will be discussed if the effect of HIT is similar between young and old subjects when it comes to mitochondrial respiratory capacity. Furthermore it will also be discussed if HIT improves glucose tolerance in a similar way as endurance training, and if this potential improvement can be linked to an improved ROS level in the skeletal muscle.

ARE RESISTANCE TRAINING-INDUCED IMPROVEMENTS OF MITOCHONDRIAL FUNCTION EFFECTIVE FOR THE MANAGEMENT OF METABOLIC DISEASES?

PESTA, D.

IInstitute for Clinical Diabetology, Research Group Energy Metabolism, German Diabetes Center (DDZ), Leibniz Center for Diabetes Research at Heinrich Heine University Düsseldorf, Düsseldorf, Germany

The prevalence of type 2 diabetes (T2D) is rapidly increasing with about 9% of the adult population affected worldwide, thus putting an enormous economic burden on healthcare systems. Non-pharmacological treatment strategies to manage and prevent this disease are urgently needed. Resistance training is gaining recognition as an effective means to promote health benefits through an increase in muscle mass and strength. However, resistance training can induce health benefits beyond those associated with augmented skeletal muscle mass, such as qualitative adaptations within skeletal muscle including enhanced glucose transport and improved mitochondrial function. Impaired mitochondrial function is frequently observed in individuals with T2D and is implicated as one of the underlying causes for T2D progression. In particular, mitochondrial adaptations triggered by resistance training provide evidence for this type of exercise as a promising lifestyle recommendation to combat T2D. Future clinical intervention studies in humans should elucidate the link between resistance training and mitochondrial function in order to validate the benefits of this training modality on mitochondrial adaptations in individuals with type 2 diabetes.

MITOCHONDRIAL FUNCTION, HYPOXIA AND REACTIVE OXYGEN SPECIES - FRIEND OR FOE?

BAILEY, D.

University of South Wales

Photosynthesising cyanobacteria breathed life into what was, until a billion years ago considered a reductive atmosphere, thus providing a selective pressure for the evolution of (oxygen) O₂-dependent micro-organisms that began with the autotrophic eukaryotes. Since these primordial times, the respiring mammalian cell has become entirely dependent on molecular O₂ since it serves as the terminal electron acceptor in mitochondrial oxidative phosphorylation and multiple enzymes require O₂ as a substrate. The human brain exemplifies this reliance on O₂ since, unlike most other tissues, it is committed to a continually active state. However, this obligatory high rate of cerebral O₂ consumption comes at a cost, since it is associated with a correspondingly high vulnerability for failure. Given that the brain's O₂ supply is so delicate, it would seem likely that evolution has favoured a feedback mechanism that senses tissue pO₂ and consequently transmits a signal to the vasculature coupling local O₂ delivery to tissue metabolic demand. Though traditionally considered damaging toxic "accidents of chemistry" (the bad and ugly!), the current presentation will reappraise emerging evidence for mitochondrial reactive oxygen species (ROS) as "upstream" signal transductants that can signal the onset of hypoxia through thiol redox signaling and "down-stream" activation of transcription factors and initiation of post-translational responses that collectively serve to defend vascular O₂ homeostasis (the good!).

APPLICATIONS OF HEAT ACCLIMATION FOR COMPETITIVE SPORT PERFORMANCE

DAANEN, H.

TNO

Introduction It is well established that competition in the heat without sufficient heat acclimation (HA) prior to the event leads to sub-optimal performance. It is however less clear how the period of heat acclimation interferes with the tapering process. Methods The literature describing experiments regarding de-acclimation and re-acclimation is reviewed with special focus on the duration of physiological process changes and compared to the literature on tapering. Results In contrast to common belief, several papers (e.g. Weller et al., 2007; Daanen et al. 2011) show that the positive effects of HA are maintained for at least a month, and that the full state of HA can be reestablished in only 3 days of re-acclimation. Discussion The finding that HA is maintained for a long period of time enables the reduction of exercise intensity several weeks prior to the event in the heat. Thus, the recommendations to taper for 8-14 days (LeMeur et al. (2012)) can be accommodated. It is, however, recommended to reserve a few days for re-acclimation just prior to the event. HIGH INTENSITY TRAINING AT ALTITUDE FOR TEAM SPORTS ATHLETES

FAISS, R.

University of Lausanne

Athletes seem compelled to include some forms of altitude training in their preparation expecting additional performance gains compared to equivalent training at sea-level. For long, they spent weeks at altitude to enhance oxygen delivery to the muscles with "live high-train high" or "live high-train low" altitude camps. For the last twenty years, the development of hypoxic facilities largely facilitated various forms of "live low-train high" (LLTH) methods where athletes live at or near sea level but train in hypoxia. Until recently, most LHTL strategies involving any form of continuous or intermittent training in hypoxia were classified under the "intermittent hypoxic training" (IHT) denomination. A comprehensive analysis IHT studies highlights only poor extra benefits of adding a hypoxic stimulus for sea-level performance improvement despite positive molecular adaptations observed after various IHT modalities (2). To overcome some limitations hindering additional performance benefits with hypoxia, our research group recently developed novel maximal intensity exercise proto-

cols in hypoxia, e.g., repeated sprint training in hypoxia (RSH) (3), incidentally well adapted to team sports athletes. Fundamental mechanisms (likely with positive adaptations in the behaviour of fast-twitch fibres) underpin the efficacy of RSH and differentiate it from IHT in the updated panorama of contemporary altitude training methods (5). With RSH, performing 'all-out' efforts in hypoxia may provide additional activation of anaerobic and neuromuscular pathways beyond that observed in normoxia. The role of exercise intensity per se in the training induced responses in hypoxia should now be recognized and RSH may indeed potentiate the effects of adding a hypoxic stress to a training stimulus by challenging at most the adaptive mechanisms of the tissue working in hypoxia to promote subsequent performance gains in normoxia (4). Although there is no consensus on best-practice strategies with altitude training for team sports, adding RSH during an altitude training camp may trigger most adaptive mechanisms for improved team performance (1). Although numerous factors influence match running performance and overall game results in team sports, individual player performance improvement is crucial. Proposing RSH in team sports may thus boost players' physical performance, prepare their organism to subsequent more sports specific training and potentially delay premature in-match fatigue. COMBINING HEAT AND ALTITUDE TRAINING

RACINAIS, S.

Aspetar Orthopaedic and Sports Medicine Hospital

Originally in the form of terrestrial altitude, altitude exposure has evolved to the 'living high – training low' model to maintain sea-level training intensity while promoting haematological adaptations (i.e. an increase in haemoglobin mass). More recently, repeated-sprints at altitude have also been shown to improve aerobic performance due to specific muscle adaptations. However, despite these refinements in altitude / hypoxic training methods, more and more athletes are looking for other training environments such as heat-acclimation. Two years ago, the number of AFL team going to hot ambient conditions for their pre-season training camp was even higher than the number of team going to altitude. This increasing interest for heat acclimation is linked to recent studies suggesting that this might improve performance in temperate conditions as well as at altitude via cross-acclimation pathways. Beyond comparing altitude and heat adaptations, it has been suggested that these two environments could induce complementary hematological adaptations; namely, an increase in hemoglobin mass and plasma volume. Recent studies have examined this concept in elite athletes. This is of particular interest for team-sport athletes as many of the physiological adaptations are triggered by the environmental conditions allowing saving time for tactical and technical training (Buchheit et al 2013). Of note, combining altitude and heat requires careful consideration as altitude adaptations require longer than those developing in the heat. The latest research has consequently combined the short-term muscle adaptations obtained by high-intensity training in hypoxia, with the short-term cardiovascular adaptations acquired by training in the heat. This lecture will highlight the most recent and relevant findings from elite athletes, and attempt to provide recommendations for cross-acclimation training. OP-PM03 Oxygen Uptake & Metabolism

METABOLIC COST, VO₂ AND VELOCITY OF WHOLE BODY, ARMS ONLY AND LEGS ONLY SWIMMING, CONTROLLING FOR STROKE AND KICK RATE

MORRIS, K.S.1,2, SHEPHARD, M.E.1,2, OSBORNE, M.A.1,3, JENKINS, D.G.1, SKINNER, T.L.1

1: UQ (QLD, Australia), 2: QAS (QLD, Australia), 3: SAL (Australia)

Introduction Previous research examining the metabolic cost and velocity contributions of the upper and lower limbs in elite swimmers has not considered the impact of stroke and kick rate. This study aimed to determine the metabolic cost, VO₂ and velocity production of arms only and legs only swimming relative to whole body swimming at different intensities while controlling stroke and kick rate. **Method** Twenty elite swimmers completed six 200m swimming trials; two with the whole stroke (swim), two with the arm stroke only (pull) and two with the leg kick only (kick). The swim trials were completed at two submaximal intensities (60% and 75% of the fastest 200m freestyle time at the 2012 Olympic Games). In the pull trials, swimmers matched the stroke rates recorded during the swim trials, while the kick rates from the swim trials were matched in the kick trials. Oxygen uptake (VO₂) was continuously measured throughout, with metabolic cost and velocity calculated for each 200m effort. One-way repeated measures ANOVAs were used to identify differences in velocity, VO₂ and metabolic cost among swim, pull and kick trials. Results Irrespective of intensity, mean velocity and VO₂ of the pull and kick trials were lower than the swim trials ($p<0.01$). For both intensities, the metabolic cost of pull was lower than swim ($p<0.02$), while the metabolic cost of kick was equal to swim ($p>0.05$). Velocity, VO₂ and metabolic cost of the swim trial were all significantly lower than the sum of pull and kick at both intensities ($p<0.01$). When the sum of pull and kick was normalised to the magnitude of swim, the arms contributed $63.3\pm6.4\%$ and $59.7\pm4.4\%$ of velocity, utilised $55.5\pm6.9\%$ and $51.9\pm4.6\%$ of the VO₂ and were responsible for $43.9\pm9.5\%$ and $46.0\pm8.1\%$ of the metabolic cost at the low and high intensities, respectively. **Conclusion** To determine the relative contributions of the upper and lower limbs to performance, simply summing the velocity and/or energy consumption of arms only and legs only swimming, even when stroke and kick rates are matched among testing conditions, will be misleading. Normalising the sum of pull and kick data to swim data indicates that the legs may contribute more to velocity than previously reported. While VO₂ during whole body swimming appears to be divided evenly between the upper and lower limbs based on the normalised data, the upper limbs use this energy more effectively. Implementation of this testing protocol before and after a pull or kick training block will enable sports scientists to identify how the velocity contributions and/or metabolic cost of the upper and lower limb actions have responded to the training stimulus. MAXIMAL OXYGEN UPTAKE IS RELATED TO MUSCLE FIBRE OXIDATIVE CAPACITY - FROM CHRONIC HEART PATIENTS TO ELITE CYCLISTS

VAN DER ZWAARD, S., DE RUITER, C.J., NOORDHOF, D.A., STERRENBURG, R., BLOEMERS, F.W., DE KONING, J.J., JASPERS, R.T., VAN DER LAARSE, W.J.

MOVE Research Institute Amsterdam, the Netherlands

Background: Maximal oxygen uptake ($\text{VO}_{2\text{max}}$) is presumably constrained by oxygen delivery rather than mitochondria's ability to consume oxygen. It has been suggested that animals exploit only 60-80% of their *in vitro* oxidative capacity when they exercise at $\text{VO}_{2\text{max}}$. In humans, however, the quantification of mitochondrial overcapacity remains unclear. *In vitro* fibre $\text{VO}_{2\text{max}}$ under hyperoxic conditions can be predicted from succinate dehydrogenase (SDH) activity in muscle fibres, which therefore enables quantification of the difference between $\text{VO}_{2\text{max}}$ and *in vitro* oxidative capacity in humans. **Purpose:** To determine to what extent $\text{VO}_{2\text{max}}$ attained during cycling exercise differs from *in vitro* oxidative capacity as predicted from SDH activity of the vastus lateralis muscle in chronic heart failure patients, healthy controls and elite cyclists. **Methods:** Forty-eight subjects (28 elite cyclists and 20 healthy controls) performed maximal incremental cycling exercise to determine $\text{VO}_{2\text{max}}$ normalized to body weight. Biopsy cryosections from m. vastus lateralis were incubated for SDH activity, which was quantified by microdensitometry. Similar data of 13 chronic heart failure patients and 6 controls were obtained from Bekedam et al. (1). *In vitro* oxidative capacity normalized to body weight was predicted from SDH activity in 67 subjects using estimated skeletal muscle mass and the relationship between *in vitro* fibre $\text{VO}_{2\text{max}}$ and SDH activity of isolated single muscle fibres and myocardial trabecula under hyperoxic conditions (2). SDH activity was corrected for estimated quadriceps muscle temperature at maximal effort. **Results:** Predicted *in vitro* $\text{VO}_{2\text{max}}$ is closely related to $\text{VO}_{2\text{max}}$ measured during cycling ($r^2 = 0.88$, $p < 0.001$), indicating that SDH activity is an important determinant of $\text{VO}_{2\text{max}}$ across patients, controls and elite cyclists ($\text{VO}_{2\text{max}}$ ranging from 9.8 to 79.0 ml/kg/min). The relationship between predicted *in vitro* $\text{VO}_{2\text{max}}$ and measured $\text{VO}_{2\text{max}}$ (slope = 0.79 ± 0.04 $p < 0.05$; intercept = 2.5 ± 2.1 , $p > 0.05$) differs significantly from the line of identity indicating that also humans do not fully exploit their oxidative enzyme capacity (~85%). **Conclusion:** Human maximal oxygen uptake and oxidative capacity predicted from skeletal muscle SDH activity are closely related but are not equal likely due to limited oxygen supply to muscle mitochondria. THE METABOLIC COST OF QUADRUPEDAL WALKING IN HUMAN

KINUGASA, R., KUBO, S., OGANE, R.

Kanagawa University

Introduction Human quadrupedalism may provide us with some important clues about the transition from quadrupedality to bipedality, but the nature and efficiency of human quadrupedal walking remains unknown. The purpose of this study was to compare oxygen consumption and muscle activity between quadrupedal and bipedal walking in human. **Methods** Five male volunteers participated. A three speeds, 1.0, 1.5, 2.0 km h⁻¹, were examined in bipedal and quadrupedal methods as the subjects walked on a treadmill. During treadmill walking, oxygen consumption and surface electromyography (EMG) were collected. The net rate of oxygen consumption was divided by body mass, and the mass-specific rate of oxygen consumption was calculated for speeds matched to the walking. This rate of oxygen consumption was then divided by speed to give the mass-specific cost of transport (COT, ml of O₂ kg⁻¹ m⁻¹), the cost to travel a meter. Surface electrodes were placed over the 12 muscles (lower limb 5 muscles; upper limb 5 muscles; trunk 2 muscles). The EMG signal for each muscle was full-wave rectified and averaged. **Results** The mass-specific COT for quadrupedal (ranged 0.416–0.480 ml of O₂ kg⁻¹ m⁻¹ in three different speeds) walking was much expensive than bipedal (ranged 0.102–0.114 ml of O₂ kg⁻¹ m⁻¹ in three different speeds) walking ($P < 0.05$). A significant trend was not found between COT and walking speed. The EMG for almost muscles was much greater in quadrupedal walking than in bipedal walking ($P < 0.05$), except for calf muscles. **Discussion** We found that human quadrupedal walking is more costly than bipedal walking. This finding is not consistent with previous work on juvenile chimpanzees (Taylor & Rowntree, 1973), which indicated that bipedal and quadrupedal locomotion were equally costly. Therefore, differences in bipedal and quadrupedal cost may be varied among individual species. Differences in kinematics and muscle activation explained observed differences in cost between bipedal and quadrupedal walking. An increase in EMG and longer contact time, which defined as the duration of foot-ground contact for one step, by approximate 350% during quadrupedal walking compared with bipedal walking. This difference corresponds closely to observed 332% increase COT during quadrupedal walking. **References** Taylor CR, Rowntree VJ. (1973). Science, 179, 186–187 Contact rk@jindai.jp

INFLUENCE OF "PRIMING" EXERCISE ON PULMONARY OXYGEN UPTAKE AND MUSCLE DEOXYGENTATION KINETICS DURING HEAVY-INTENSITY CYCLE EXERCISE IN TYPE 2 DIABETES.

ROCHA, J.I, GILDEA, N.I, O'SHEA, D.2, GREEN, S.3, EGANA, M.1

1:School of Medicine, Department of Physiology, Trinity College Dublin, Dublin 2, Ireland. 2:Endocrinology, St Columcille's and St Vincent's Hospitals, Dublin, Ireland. 3:School of Science and Health and School of Medicine, University of Western Sydney, Sydney, Australia. We tested the hypothesis that priming exercise (PE) would increase the speed of the adjustment of the primary phase ($t_{\text{aup}}, t_{\text{p}}$) of pulmonary oxygen uptake (VO_2) and/or reduce the amplitude of the slow component of VO_2 during high-intensity cycling in type 2 diabetes (T2D) given that muscle oxygen supply appears to be limited in T2D. Ten middle-aged participants with uncomplicated T2D (49.6 ± 7.2 years, 30.8 ± 5.0 kg.m²; 8 men / 2 women) and 10 non-diabetic (ND) controls (44.6 ± 9.2 years, 30.8 ± 4.2 kg.m²; 8 men / 2 women) were recruited. Participants completed four bouts of constant-load cycling corresponding to 50% between their ventilatory threshold and VO_2 peak power outputs, (i.e. 50% Δ) previously established during a ramp incremental test. Two of these bouts were completed without priming exercise and two bouts were undertaken with prior heavy-intensity (50% Δ) priming exercise. VO_2 kinetics was calculated from continuously measured breath-by-breath data, while the rate of muscle deoxygenation (i.e., deoxygenated hemoglobin, HHb) was continuously measured by near-infrared spectroscopy (NIRS) at the vastus lateralis muscle. At baseline the time constant of the primary phase, t_{p} , was approximately 17% slower ($P > 0.05$) in T2D, and PE tended to reduce t_{p} ($P = 0.06$) in both groups by a similar magnitude (T2D, 37.9 ± 17.7 vs. 33.7 ± 10.6 s; ND, 31.0 ± 5.8 vs. 28.0 ± 6.3 s). The amplitude of the slow component (A_{s}) was overall significantly lower ($P < 0.05$) in T2D; and PE tended to overall reduce it ($P = 0.09$). These reductions were of approximately 50% in T2D and only 5% in ND controls (T2D, 0.29 ± 0.13 vs 0.18 ± 0.10 L.min⁻¹; ND, 0.39 ± 0.18 vs 0.37 ± 0.21 L.min⁻¹), however, there was no significant interaction between diabetes status and priming bout in A_{s} ($P = 0.22$). The rate of adjustment or amplitude of deoxygenated haemoglobin (HHb) did not show

any differences between groups. These preliminary data suggest that in middle-aged adults with T2D, priming exercise prior to heavy-intensity exercise can potentially speed the primary phase VO₂ kinetics and reduce the amplitude of the slow component possibly due to an improvement in oxygen delivery. Nevertheless interindividual variability in responses precluded the attainment of statistical significance. Borgespj@tcd.ie

HIGH INTENSITY INTERVAL TRAINING IN HANDCYCLING: THE EFFECTS OF A 7 WEEK TRAINING INTERVENTION IN ABLE-BODIED MEN.

SCHOENMAKERS, P.P.J.M.1, REED, K.E.1, VAN DER WOUDE, L.H.V.2, HETTINGA, F.J.1

University of Essex

1University of Essex, Colchester, United Kingdom. 2University of Groningen, Groningen, the Netherlands. INTRODUCTION: In handcycling, a high maximal oxygen uptake (VO_{2peak}) and high peak power output (POpeak) show to be important determinants of race performance (Fischer et al., 2015). To achieve successful endurance performance, optimal training is a necessity to improve the physiological capacity of athletes. Unlike most endurance sports, propulsion in handcycling depends on the endurance and muscular capacity of the upper body, and limited research is available how to improve this endurance capacity. The aim of the current study therefore was to evaluate the effects of high intensity interval training (HIIT) and continuous training (CT) on the physiological capacity and handcycling performance of able-bodied men in a well controlled laboratory setting. METHODS: 24 Recreational active men (22±2 years; 184±4 cm; 79±10 kg) were matched on incremental handcycle pretest performance and then randomly assigned to HIIT, CT or a non-training control group (CON). Participants in HIIT and CT visited the lab three times per week for seven weeks, to complete a total of 21 training sessions. HIIT completed 14 training sessions of 4x4 minutes intervals at 85% heart rate reserve (HRR) and 7 continuous training sessions at 55% HRR (every 2nd session). CT performed 21 training sessions of 30 minutes at an average training intensity of 55% HRR. After the intervention, changes in VO_{2peak} and POpeak were compared between HIIT, CT and CON. RESULTS: Baseline testing showed no differences between groups in participants' characteristics. The average external training load per training session was higher in CT compared to HIIT, but not significantly different (2.32±0.3kJ vs 2.28±0.3kJ respectively, p>0.05). Improvements after HIIT in VO_{2peak} (+22.2%) and POpeak (+43.7%) were significantly larger (p<0.01) compared to CT and CON. Improvements after CT in VO_{2peak} (+9.7%) POpeak (+31.1%) were higher compared to CON (p<0.01). No significant changes were found in CON after the training period. DISCUSSION: As in other endurance sports, HIIT proved to be effective in improving physiological capacity and therewith handcycle performance. Whilst physiological capacity in both training groups improved significantly compared to CON, the present study shows that VO_{2peak} and POpeak improved more after HIIT than after CT in able-bodied men. This is despite HIIT taking 22% less time than the CT. It is therefore advised to include high intensity interval training into training regimes of competitive handcyclists. Invited symposia**IS-BN05 INTEGRATIVE FALL PREVENTION – NOVEL STRATEGIES TO TEST AND TRAIN NEUROMUSCULAR AND CARDIAC FALL RISK FACTORS IN THE ELDERLY****DOES HEART RATE VARIABILITY SERVE AS A POTENTIAL FALL RISK FACTOR IN THE ELDERLY?**

PECCHIA, L.

University of Warwick

Biomedical signals reflecting autonomous nervous system (ANS) and cardiovascular system (CVS) could be promising means to assess the risk of falling and to predict accidental falls in the short term. The association between HRV and risk of falling was first investigated in 2015, with a retrospective study enrolling 168 subjects over 65 years of age. Forty-seven of them experienced fall events within 3 months since registration. Using data-mining methods, abnormal HRV patterns were discovered and the odds ratio (OR) of falling in subjects exposed to these patterns was analyzed. The OR of falling in subjects presenting these depressed HRV pattern was significant (OR 4.32, CI 95% 1.61-11.56, p<0.01), suggesting that a depressed HRV was associated with an increased risk of falling (Melillo et al. 2015). A Multinomial Naïve Bayes classifier achieved satisfactory results through a rigorous validation procedure, enabling to predict fallers within three months from the baseline recordings with a sensitivity rate of 72% and a specificity rate of 61% (Castaldo et al 2016). The proposed method was based on 1 hour ECG recording and short term HRV analysis, which are already in use in many outpatient clinics and could be used widely in outpatient settings to identify high-risk patients who need further assessment and could benefit from fall prevention programs. Starting from these results, we focused on the prediction of specific risk factors that are clearly dependent form ANS/CVS states, which can be reliably detected using HRV. In a recent study, we developed, validated and patented a mathematical model to predict orthostatic hypotension by analyzing HRV features recorded in the few minutes (from 2 to 5min) before rising from a bed or chair, which account for the 30% of indoor falls. This model predicted the drop down of blood pressure with an error below 4mmHg, which is the measurement error (Sannino et al. 2015). This lecture will present these results, the methods used and their potential future applications and limits. 1. HOW DOES TRAINING TO BALANCE ON UNSTABLE SURFACES CHANGE BALANCE CONTROL MECHANISMS?

VAN DIEËN, J.

VU University Amsterdam

Balance training on unstable objects reduces fall risk in older adults (1), but the underlying mechanisms are unclear. Therefore, we investigated motor and sensory changes underlying improvements in balance in unipedal stance on an unstable object. Fourteen participants practiced to balance on one leg on a board that could freely rotate in the frontal plane. They performed 6 16-seconds trials standing on one leg on a stable surface (2 trials without manipulation, 2 with vestibular and 2 with visual stimulation) and 6 trials on the balance

board, before and after a 30-minutes training. Center of mass (COM) movement, segment and total angular momenta and board angles were determined. Trials on stable surface were compared to trials after training, to assess effects of surface conditions. Pre-training and post-training trials were compared to assess rapid (between pre-training trials) and slower (trials before and after training) learning and sensory manipulation trials were compared to unperturbed trials, to assess sensory weighting. COM excursions were larger on the unstable surface, but decreased rapidly with practice. Changes in angular momentum contributed more to COM acceleration on the balance board, but this contribution decreased with practice. With practice, effects of visual and vestibular stimulation increased rapidly. Initially, oscillations of the balance board occurred around 3.5 Hz, which decreased with practice. The initial decrease in sway was associated with up-weighting of visual information, while later changes were associated with suppression of oscillations that we suggest are due to too high proprioceptive feedback gains. The present results are in line with findings of decreased proprioceptive gains after slackline training(2), and indicate that proprioceptive training may be a misnomer for balance training on unstable surfaces. Training gains related to up-weighting of visual information suggest that emphasis on the use of vision in balance training may be beneficial and that interventions specifically targeting vision and strategies to obtain visual information, such as avoiding to look at ones feet, should be tested in fall prevention. 1. ACUTE AND INTERVENTIONAL EFFECTS OF EXERCISE TRAINING ON POSTURAL CONTROL IN SENIORS: APPLICABILITY OF NOVEL TRAINING REGIMES

DONATH, L.

University of Basel

Adequate balance and strength training in seniors improve relevant neuromuscular fall risk parameters and can reduce the risk of falling up to 50% (Granacher et al., 2011). In turn, acute exercise (moderate, intense and under hypoxia) yields transient deterioration of static postural control after exercise cessation (Donath et al., 2013, Donath et al., 2014c). Firstly, the present talk provides an overview of the magnitude and extent of exercise-induced alterations of postural control and limb muscle activity. A post-exercise neuromuscular fall-window will be debated. Secondly, three interventional studies of our group (one- vs. two-step stair climbing, fall training, slackline training) that intent to improve relevant cardiocirculatory and neuromuscular fall-risk factors in seniors will be discussed (Donath et al., in revision, Donath et al., 2014b, Donath et al., 2014a) in the context of available RCTs on neuromuscular performance and fall risk in seniors. Finally, an integrative training approach targeting strength, balance and endurance requirements via complex movement patterns with progressively applied and carefully increasing accelerations, decelerations, stop and go patterns, change in directions, eccentric plyometrics and rotations with demanding spatial orientation tasks will be introduced. IS-BN06 EVIDENCE BASED SPORT PHYSIOTHERAPY: UNWEIGHTING AS A TOOL FOR EARLY RETURN TO SPORT?

NEURAL AND KINETIC ADJUSTMENTS IN SHORT TERM UNWEIGHTING RUNNING

NICOL, C.1, SAINTON, P.1, CABRI, J.2,3, CHAVET, P.1

1: AMU (Marseille, France), 2: NSSS (Oslo, Norway), 3: LUNEX (Luxembourg)

Introduction Lower body positive pressure (LBPP) technology provides the opportunity to study the neuromechanical adjustments to partial unweighting and reloading over repeated running cycles. Unweighting leads to decreased vertical ground reaction forces (e.g. Grabowski and Kram, 2008) and to mirrored changes with reloading (Sainton et al. 2015). However, despite the reduced leg muscle activities previously reported (Liebenberg et al. 2011; Hunter et al. 2014), Sainton et al. (2015) revealed different neural adjustments during the pre-and post-impact phases. This study focuses on the time course of the neuromechanical adjustments. Methods Nine healthy males performed 2 randomized runs of 9 min at preferred speed on an LBPP treadmill. Each series included 3 successive running conditions of 3 min (at 100% body weight (BW), 60 or 80% BW). The unweighting and reloading transition phases were progressively initiated and lasted 10-15 s. Vertical ground reaction forces, center of mass accelerations and surface electromyographic (EMG) activity recorded from 7 leg muscles were analysed for the first and last 30 s of each running condition as well as along the transition phases. Results Unweighting led to increased flight time, unchanged contact time and reduced vertical ground reaction forces whereas reloading resulted in opposite changes. During both transitions most mechanical changes varied linearly with the LBPP-induced BW changes, so that only few parameters differed between the end of the transition and once the running pattern stabilized. The preactivation phase presented for most muscles no EMG change whereas the braking and the push-off phases revealed selective changes of the thigh and shank muscle activations, respectively. Discussion This study demonstrates for the first time the linearity of the relationships between the unweighting- and reloading-induced changes with most mechanical stride parameters. Distinct neural adjustments during the preactivation, braking and push-off phases as previously observed are confirmed (Sainton et al. 2015). The unchanged preactivation of most muscles reinforces the major intervention of passive mechanisms before impact (Müller and Blickhan 2010), but the effect of the lack of visual cues at foot touchdown during LBPP running remains to be investigated. The braking and push-off phase EMG analyses highlight mirrored progressive adjustments to unweighting and reloading while emphasizing the inter-muscular differences. Considering the use of LBPP treadmill in rehabilitation, additional detailed studies are needed on the neural adjustments over longer and repeated periods of running. References Grabowski AM, Kram R. SHORT-TERM INFLUENCE OF UNWEIGHTING ON MUSCLE FASCICLE LOADING

ISHIKAWA, M., SANO, K., KUNIMASA, Y., MAKINO, A., KOMI, P.V.

Osaka University of Health and Sport Sciences

Unweighting treadmill devices with lower body positive pressure (LBPP) technology have been recently used as a tool for the postoperative rehabilitation after lower limb injuries. The advantages of these devices can reduce impact forces, rates of force development and muscle activities during the LBPP running (Sainton et al. 2015, Liebenberg et al. 2011). However, the effects of unweighting on neuromuscular system have not been fully investigated during human locomotion. For example, the tendon loading can influence the contributions of afferent feedback to locomotor muscle activities (af Klint et al 2009) and efficacy of utilization of tendon elastic energy (e.g. Ishikawa and Komi 2008) during human locomotion. The question we have to ask here is how unweighing and reloading situations would influence our neural and mechanical systems during stretch-shortening cycle (SSC) exercises, such as running and jumping. In general, impact forces can be utilized to enhance the performance and efficiency as the elastic strain energy in tendon and stretch-induced reflex potentiation in muscle fascicles during locomotion. As similar to the intensity and movement specific muscle fascicle regulation (e.g. Ishikawa and Komi 2008), unweighing and reloading conditions can modify muscle fascicle length not only in standing but also in movement conditions. At standing, for example, the muscle fascicles of gastrocnemius and soleus muscles are getting longer (8.0%, at the 20% of body weight) and Achilles tendon are shorter (2.0-3.0%, at the 20% of body weight) with unweighting. In this presentation, we will show how muscle fascicles and tendons are modified as well as behave during SSC exercises with unweighing and reloading situations. The gastrocnemius medialis and Achilles tendon length during running and hopping were measured by musculoskeletal ultrasonography together with muscle activities and ground reaction forces, simultaneously. These short-term adjustments of muscle-tendon interaction during SSC exercises with unweighting can also provide the potential mechanism of afferent feedback contribution to locomotor muscle activities. LOWER BODY POSITIVE PRESSURE RUNNING: A TOOL FOR EARLY RETURN TO SPORT?

CABRI, J.1, NICOL, C.2, ISHIKAWA, M.3, CHAVET, P.2

(1) Norwegian School of Sport Sciences, (2) Aix-Marseille Université, (3) Osaka University of Health and Sport Sciences

Several studies have investigated the effects of reducing gravity on locomotion kinematics and kinetics. Lower body positive pressure (LBPP) treadmill allows running in partial unweighing conditions and is proposed as a tool for early return to sport. This invited symposium focuses on the influence of short term unweighing on running patterns. Quantifying the pre- and post-impact phase lower limb muscle activities and muscle-tendon loading in healthy as well as in patients 6 months after ACL reconstruction, it provides a multi-scale screening of partial unweighing effects on locomotor patterns. The first presentation entitled "Neural and kinetic adjustments in short-term unweighing running" deals with the unweighing and reloading induced-changes in the vertical ground reaction forces and of the activity of major lower limb muscles. Special emphasis is put on the timing of neuromechanical changes. Short-term unweighing and reloading are found to result in mirrored changes. The unweighing phase shows increased flight time with unchanged contact time. In the absence of modification of the triceps surae EMG during preactivation and braking, the observed overall decrease in vertical ground reaction forces is attributed to the vertical support provided by the anti-gravity treadmill chamber. The increased EMG stability with body weight reduction is considered as a protective mechanism facing such unusual loading condition. This limits the expected improvement in running economy, but favors the readjustments to normal body weight condition. The after-effects highlight the fact that 3 min of unweighing are sufficient for an updating of the running pattern. The second presentation focuses on "the short-term influence of unweighing on muscle fascicle and tendon loading" in standing, hopping and running conditions. As similar to the intensity and movement specific muscle fascicle regulation, unweighing and reloading conditions can modify muscle fascicle length not only in standing but also in movement conditions. However, it is not clear how our neuromuscular system is regulated under unweighing and reloading conditions. This presentation highlights muscle-tendon interactions together with the neural adjustments during human movements under unweighing and reloading conditions. The third presentation is dealing with "the use of unweighing running to detect proprioceptive functional impairments". ACL ligamentoplasty leads to long lasting proprioceptive and functional deficits. In rehabilitation, LBPP treadmill running is considered allowing earlier return to practice. Our own running protocol performed 6 months post ACL reconstruction revealed increased interlimb asymmetry in temporal dynamics and muscle activity while running in unweighing conditions. This highlights the interest of such protocol for detecting remaining locomotor impairments.

Invited symposia**IS-SH05 PSYCHOLOGICAL DISORDERS IN ELITE SPORTS****BURNOUT AND DEPRESSION IN HIGH LEVEL YOUNG ATHLETES**

BECKMANN, J., NIXDORF, I., FRANK, R.

Technical University Munich

Burnout and Depression in High Level Young Athletes Introduction Previous research has shown high levels of chronic stress, coping strategies, and the balance of physical and psychological stress and recovery to influence the development of burnout and depression in elite athletes (Nixdorf et al., 2013). High level young athletes seem to be especially vulnerable to these factors. To deal with this problem a burnout and depression screening instrument for young athletes was developed based on the findings from 3 studies. Methods In a cross-sectional study (Nixdorf et al., submitted), questionnaires on Team Cohesion, Perfectionism in Sport, Sport Attributional Style, and Depression were administered to German junior elite athletes ($N = 199$; $M \text{ age} = 14.96$; $SD = 1.56$). The data was analyzed by a mediator analysis using path analysis with bootstrapping. In a longitudinal study with 3 repeated measures ($N=246$; $M \text{ age}=15.22$; $SD=1.99$), in addition to depression athlete burnout was assessed along with experienced stress and recovery. A qualitative study further explored major stressors in elite athletes (Nixdorf et al., 2015). Results In all 3 studies athletes in individual sports showed significant higher scores in depression than athletes in team sports. In the cross-sectional study attribution after failure accounted for a mediation with a significant indirect effect ($\beta = .07$; $p < .05$) and significant coefficients with sport discipline ($\beta = .27$; $p < .001$) and to the dependent variable depre-

sion ($\beta = .26$; $p < .01$). Whereas cohesion showed a significant negative relationship to depression, perfectionism was positively related to depression. In the longitudinal study a medium correlation between burnout and depression was found ($r = .52$, $p < .001$). The qualitative study detected three main sources of stress: double burden, sport specific demands and conditions. Discussion All 3 studies furnished concurrent findings on sport specific mechanisms contributing to depressive syndromes and burnout in high level young athletes. The assessment instruments used in the longitudinal study proved to be relevant for an early assessment of burnout and depression symptoms. They were included in a screening instrument that is further tested. References Nixdorf, I., Frank, R., Hautzinger, M. & Beckmann, J. (2013). WHEN ACHIEVEMENT STRIVING GOES AWRY: CHALLENGING THE DUAL NATURE OF PERFECTIONISM

HALL, H.

York St John University

This presentation sets out to challenge arguments put forward in support of the dual nature of perfectionism. In particular, the idea that perfectionism, with its accompanying tendency for overly critical evaluation (Stoeber, 2011), can manifest as a universally constructive quality, which not only activates striving to achieve exacting standards, but elicits performance appraisal processes with the capacity to sustain adaptive patterns of motivation and foster psychological well-being. The presentation will demonstrate that perfectionism is a complex multidimensional personality characteristic that reflects an irrational way of thinking about achievement, which makes it difficult to sustain adaptive motivational qualities and endorse personal mastery especially when experiencing adversity (Flett & Hewitt, 2016; Hall 2016). While perfectionism may energise motivation and bring about exceptional accomplishments, under adverse conditions it is always likely to trigger dysfunctional cognition that may lead to performance impairment and emotional distress. The presentation will outline why perfectionism is best thought of as a source of vulnerability in sport participants and it will offer some thoughts about research strategies that might be employed to examine that contention. It will first reflect upon the paradoxical effects of perfectionism and challenge arguments put forward to suggest that perfectionism can manifest in both adaptive and maladaptive forms. It will further contend that whether perfectionism is considered to be a trait, an inter-personal style or a pattern of ruminative thought, it is difficult to argue that it is capable of evoking universally adaptive qualities that will facilitate either sustained performance or psychological well-being in athletes performing at any level, unless it is accompanied by other sources of resilience. The presentation will then outline important psychological mechanisms and processes that are elicited by perfectionistic thinking, in order to illustrate why perfectionism is a vulnerability factor. It will critically evaluate the emerging research base in sport and physical activity to explain what is known about the influence of perfectionism. Finally, it will provide some thoughts on new research directions which will further challenge arguments that have been put forward in support of the dual nature of perfectionism. References Flett G. EFFECTIVE PREVENTION OF BURNOUT IN ELITE ATHLETES AND HIGH-LEVEL COACHES

LEMYRE, P.

Norwegian School of Sport Sciences

It has been argued that only individuals originally fueled by a passion or a sacred fire for their involvement and dedication to an activity, may experience the debilitating consequences of burning out (Pines, 1993). Representing more than a simple reaction to an accumulation of stress, burnout in athletes and coaches is a multidimensional syndrome that is typically manifested by a feeling of dysphoria affecting the welfare of the individuals, leading to a reduction in the levels vitality and the quality of motivation, as well as as affecting of the individuals' efforts towards a desired goal. Based on a series of subsequent studies on elite athletes and high-level coaches, this presentation will make the argument that the early identification of at-risk profiles represents an effective measure to prevent burnout in elite athletes and high-level coaches. Athletes and coaches motivated by unrealistic or unstable goals are more predisposed to develop symptoms of burnout and engage in a downward spiral leading individuals from exhaustion to disengagement from sports. While most athletes and coaches will typically describe their initial commitment to sports as being highly intrinsically motivated, these reasons for being involved in sports may change during a season or a career. When their motivation becomes purely extrinsic or that they lose the motivation to be involved in sports, as they persist in their sport-related role they will become increasingly at-risk of burning out (Lemyre, Hall, & Roberts , 2008; Bentzen, Lemyre, & Kenttä, 2015). Their actions are no longer self-determined, an imbalance develops between the perception of effort and the perceived return on personal investment in sports. Current study findings clearly suggest that assessing one's motives for competing or coaching in sports, one's perceived achievement climate and felt level of need support, as well as one's perceived level of competence and expression of perfectionist tendencies, allows for a reliable identification of at-risk profiles burnout. Subsequent systematic monitoring of changes in quality of motivation and perceived need support in individuals with at-risk profiles serves an effective prevention tool to justly intervene prior to coaches and athletes burning out. Invited symposia**IS-SH06 (SELF-)IMPROVEMENT IN AND THROUGH SPORTS AND PHYSICAL EXERCISE – HISTORICAL PERSPECTIVES**

THE CREATION OF THE BODY UNDER THE FITNESS-PARADIGM SINCE THE 1970S IN CENTRAL EUROPE

MUELLNER, R.

University of Vienna

Andreasson & Johansson (2014) argue that within the last four decades fitness has become a "global industry" with a sales volume of around about 75.7 billion U.S. \$ per year, with 153.000 fitness clubs and with 131.7 million club members. These numbers indicate the importance of the phenomenon fitness and justify a systematic scientific analysis of the modern fitness culture and also of its historic development. This paper focuses not only on the organizational history of the modern fitness cultures on its way from the USA to Western Europe but also asks how and if the fitness movement can be examined more generally under the theoretical framework of fordist and post-fordist sports. The key elements of the shift can be found especially in the number and type (age, gender) of participants, the forms and types of organization, the contents and goals or in changing body concepts. In particular we are going to focus on the important aspect of how ideals of being and keeping fit have become hegemonic in society and how fitness practices have been adopted by individuals. Thus, we follow Foucault's concept of "Biopolitics" and additionally the theorists of post-fordist subjectivation theory. We assume that the power which controls the body has shifted to the individual. That means that self-control and self-monitoring have become more and more common. Fitness has become a physical practice situated between "self-submission" and "self-empowerment".

WHAT'S NATURAL? TECHNOSCIENCE AND THE FEAR OF CYBORGS IN SPORT.

GUENTER, S.

University of Hannover

Since there are sporting competitions, there is also something like body enhancing technology. The use of performance-enhancing technical devices and supplements has a long history, stretching back to Ancient Greece and continuing within contemporary sport. While in the ancient world mostly dietary methods were used to improve performance, nowadays we deal with hormones, technical devices or even doped genes. 'Human Enhancement' is a fascinating prism that reflects questions of participation, justice, equality and the autonomy of the subject in the social fields of sport. The area of elite sports is particularly affected by 'human Enhancement', according to the principle of exceeding what has come before, of aiming higher, faster and further. This paper analyses the postulated 'naturalness' in the regulative and normalising function in the area of elite sports, in connection with Foucault's theory of governmentality and the methods of critical discourse analysis. Using different historical and current cases, the negotiating processes in relation to the argumentation logic, dynamics and resistance in shifting distinctions are presented using the fundamental documents of the IOC, IPC, CAS and IAAF. Represented through the inclusion and exclusion processes are hierarchies of the body that are [re]consolidated and transformed. The central question emerges as to how the worth of equal opportunity and fairness in regard to 'naturalness' has been reconsolidated or/and transformed in the past and present. TRANSFORMATIONS IN THE ACCEPTANCE OF THE DIS-EASED FEMALE BODY IN THE PUBLIC SPACE SINCE THE MID-20TH CENTURY: THE ROLE OF SPORT AND PHYSICAL EXERCISE

HOFMANN, A.

Ludwigsburg University of Education

Throughout history the female body was seen as different from the male body, weak and frail which were reasons for exclusion in many sports. The argumentation was often connected to medical explanations and health issues, as Patricia Vertinsky shows in her work "The Eternally Wounded Female Body" where she wrote about "anatomy is destiny". Still neglected is the issue of women whose bodies do not match the societal norms, because of health issues or disabilities. These women also participate(d) in physical exercises and sport, but their access to it was and still is even more difficult. Thus, this paper takes up the dis-eased female body in a double sense. 'Diseased' meaning not being comfortable in one's body due to an illness, and 'dis-eased' of what society made of the disease - in this case breast cancer, an illness that has been tabooized and stigmatized for a long time, and still is in many regions. Under the framework of Goffman's theory of "Stigma", both issues will be discussed in connection to breast cancer patients' public access to physical exercise and sport throughout the last decades. Especially Germany will be taken as an example where there are special "sport after breast cancer" classes in public sports clubs since the early 1980s.

FATIGUE AND RECOVERY OF NEUROMUSCULAR FUNCTION AFTER A SIMULATED SOCCER MATCH

THOMAS, K., DENT, J., HOWATSON, G., GOODALL, S.

Northumbria University

INTRODUCTION Soccer match-play induces transient and on-going decrements in physical function that persist for up to 72 hours post-game (Nedelec et al., 2012; Minnet & Duffield, 2014). There are frequent congested periods in the competitive schedule that require multiple games per week, separated by as little as 48 hours. Consequently, understanding and managing fatigue and the associated recovery post-match is an important consideration. Previous work has characterised the recovery of peripheral function after a soccer

match, but there is sparse data on the recovery of neuromuscular function (Rampinini et al., 2011). The aim of the study was to assess the fatigue and recovery of neuromuscular, physical and perceptual responses following a simulated soccer match. METHODS Fifteen semi-professional male soccer players completed a 90 min simulated soccer match. Pre-, immediately-post and at 24, 48 and 72 h participants completed a battery of tests. Maximum voluntary force (MVC) and twitch responses to femoral nerve stimulation during isometric knee-extensor contractions and at rest were measured to assess central (voluntary activation, VA) and peripheral (quadriceps potentiated twitch force, Qtw,pot) fatigue. Creatine kinase (CK) was analysed from capillary blood samples as a humoral index of muscle damage. Countermovement jump (CMJ), reactive strength index (RSI) and sprint performance (10 & 20 m) were assessed to profile the recovery of physical function, alongside perceptual markers of recovery (active & passive soreness, fatigue). RESULTS Simulated soccer match play elicited decrements in MVC that remained unresolved at 72 h ($P = 0.01$). Qtw,pot declined by 13% post-match ($P < 0.001$) and remained depressed until 72 h post. VA was reduced by 8% post-match and remained below baseline at 72 h ($P = 0.049$). CK was elevated post-match and remained elevated at 72 h post ($P < 0.001$). CMJ performance remained depressed at 72 h ($P < 0.01$), RSI was decreased at 48 h ($P < 0.01$) but recovered by 72 h, and sprint performance recovered by 24 h. Perceptual markers of fatigue were elevated until 48 h post ($P < 0.01$) and had recovered by 72 h. DISCUSSION Simulated soccer match-play induced significant fatigue that was both central and peripheral in origin. The loss in maximal voluntary force was not restored by 72 h post-match, and was accompanied by persistent central fatigue. The similar time-course recovery of neuromuscular function, jump performance and perceptual markers of fatigue indicates these tools might be useful as indices of fatigue and recovery in soccer players.
