Introduction Older adults are at an increased fall risk during transition tasks such as gait initiation (Melzer, Kurz, Shahar, Levi, & Oddsson, 2007). Differences found in head stability between young and older adults have been suggested to threaten balance thus increasing such risk in older adults (Laudani, Casabona, Perciavalle, & Macaluso, 2006). To identify the role of head movement on balance, we examined the effect of upper body segments acceleration and their displacement variability on whole body movement and its variability (an indicator of balance), during gait initiation. Methods Eleven young (23 ± 1 yrs) and 12 older (75 ± 2 yrs) females initiated gait at a self-selected, comfortable speed. Acceleration root mean square (RMS) values were calculated for the pelvis, trunk and head in the antero-posterior (AP), mediolateral (ML) and vertical (V) plane. Attenuation coefficients of acceleration were calculated for pelvis-head (CPH), pelvis-trunk (CPT) and trunk-head (CTH) segments in the AP and ML plane. Total linear displacement was measured for centre of mass (COM) in the AP and ML plane. Finally, angular displacement variability of the pelvis, trunk and head, and linear displacement variability of the COM were evaluated by calculation of the average standard deviation (AvgSd). Results AP RMS values were higher for the head for older compared to young (3.9 ± 1.9 m•s $^{-1}$ and 2.4 ± 1.5 m•s $^{-1}$ [$P=0.023$], respectively). Young were able to attenuate acceleration for AP CTH whilst older were not able to ($0.83\pm6.44\%$ and $-19.33\pm7.14\%$, [$P=0.02$], respectively). Young had a larger total AP COM displacement compared to old (408.2 ± 86.7 mm and 313.3 ± 33.5 mm, [$P=0.004$]); however, there were no differences in total ML COM displacement. AvgSd of angular displacement of the head was higher in older compared to young in the AP plane ($3.7\pm1.5^\circ$ and $1.5\pm0.6^\circ$ [$P=0.004$], respectively), but similar for the pelvis and trunk. Finally, there was no difference in COM AvgSd between young and older in the AP and ML plane. **Discussion** Despite older demonstrating greater acceleration of the head, damped ability to attenuate acceleration between the trunk and head, and greater variability in the movement of the head, there was no effect in the ML displacement or variability of COM in the AP and ML direction between age groups. This may be due to the head mass not being sufficiently large enough to alter COM pattern during a dynamic movement. Head instability did not appear to cause reduced balance during gait initiation in older. References Laudani L, Casabona A, Perciavalle V, Macaluso A. (2006). J Electromyogr Kinesiol, 6, 603–610. IS DYNAMIC BALANCE RELATED TO STATIC BALANCE IN HEALTHY ACTIVE OLDER WOMEN?

NETZ, Y.1, CARASSO, R.2, DUNSKY, A.1

1: Wingate (Israel), 2: Hillel Yaffe Hospital (Israel)

Introduction Both static and dynamic balance are impacted by vision, vestibular sense, proprioception, muscle strength and reaction time; both are associated with fall risks and each may be enhanced as a result of exercise (Lelard & Ahmadi, 2015). We examined whether static balance components, representing the multisensory perturbation approach, are related to dynamic balance measures. **Methods** Healthy active women ($N=78$; age 73.5 ± 5.9) were assessed during quiet standing in eight positions: Eyes open – NO; eyes closed – NC (manipulating visual input); on a pillow with eyes open – PO (manipulating the somatosensory input); and eyes closed – PC (manipulating both the visual input the somatosensory input); and the next four positions with eyes closed, all challenging the vestibular system – Head turned to the right – HR; turned to the left – HL; bent forward – HF; bent backwards – HB. Measures in each position included stability indices (ST) examining the amount of sway, and the Fourier spectrum of sway (F1-F8) examining sway intensities at different frequency ranges – F1 sensitive to visual control, F2-F4 to vestibular stress, F5-F6 to somatosensory feedback, and F7-F8 to neuropathology. Dynamic balance measures included the Time Up & Go (TUG) and a 10m walk at two speeds – one normal and one fast (time, velocity, number of steps, stride length), both of which require change of base of support, and the Functional Reach (FR) (distance) – reaching forward while maintaining a fixed base of support. **Results** As almost all balance variables are significantly correlated with age ($p<.05$), we performed age controlled partial correlations. Results showed: 1) no correlations between static and dynamic balance in most cases; 2) few correlations of TUG with F2-F4 on NC, PO, HR, HL, and HB ($r=.21\text{--}.29$); of FR with ST on HR, HL, and HF ($-.20\text{--}.27$); of FR with F4 on NC, HR, HL, HF, and HB ($r=-.22\text{--}.28$), with F5 on HF ($r=-.33$), and with F7 on PC, HR, HF ($r=-.28\text{--}.34$); 3) high correlations among the dynamic balance measurements – TUG and 10m walks ($r=.53\text{--}.63$); 4) no correlation between FR and TUG ($r=-.17$). **Discussion** Static and dynamic balance are independent of each other in healthy active older women (Muehlbauer et al., 2012), as are dynamic balance tasks performed with (TUG) and without (FR) changing the base of support. Possibly, in healthy older women important balance capacities are unrelated and should be trained in a complementary agenda to prevent falls. However, selected static balance components are correlated with dynamic balance measures, all of which are sensitive to the functioning of the vestibular system. More studies considering the unique role of the vestibular system in both static and dynamic balance are needed (Anson & Jeka, 2016), as well as exercise programs enhancing this system. EFFECT OF JAW CLENCHING ON DYNAMIC STABILITY AFTER FORWARD LOSS OF BALANCE

RINGHOF, S.1, STEIN, T.1, HELLMANN, D.2, SCHINDLER, H.J.2, POTTHAST, W.3

1: Karlsruhe Institute of Technology (Karlsruhe, Germany), 2: University of Heidelberg (Heidelberg, Germany), 3: German Sport University (Cologne, Germany)

Introduction Postural control is crucial for most tasks of daily living, delineating postural orientation and balance. Nevertheless, falls are common and serious events, and have been associated with deficits in muscle strength and dynamic stability (Blake et al., 1988). Recent studies reported that rate of force development (Ebben et al., 2008) and static postural control (Ringhof et al., 2015) were improved in response to concurrent jaw clenching activities. However, as there are no studies describing the influence of jaw clenching on dynamic postural control, the present study aimed to investigate the effects on recovery behavior after forward loss of balance. **Methods** Participants were twelve healthy young adults, who were instructed to recover balance from a simulated forward fall while either force-controlled biting (FB) at a submaximum level or keeping the mandible at rest, i.e. non-biting (NB). Bite forces were measured by means of hydrostatic splints, whereas a 3D motion capture system was used to analyze spatiotemporal parameters and joint angles, respectively. In addition, dynamic stability was quantified by the extrapolated CoM concept, designed to determine postural stability in dynamic situations (Hof et al., 2005). **Results** Statistical analyses (paired t-tests) revealed that spatiotemporal parameters and joint kinematics were both not significantly influenced by FB. Furthermore, there were no significant effects on dynamic stability in terms of the extrapolated CoM

($p=0.100$, $d=0.17$) and the margin of stability ($p=0.701$, $d=0.06$) at touchdown. Interestingly, bite forces under both conditions significantly increased from initiation of the forward fall until touchdown of the recovery limb. Discussion The results indicate that reductions in postural sway evoked by submaximum biting are not transferable to recovery behavior as it was assessed in the present study. It is suggested that these contradictions are the result of different control strategies associated with the abovementioned tasks. Furthermore, floor effects and the sample size might be discussed as potential reasons for the absence of significances. Notwithstanding this, the present study also revealed that clenching the jaw seems to be part of a common physiological repertoire used to improve motor performance. Future studies, therefore, should contrast the effects of jaw clenching activities in different populations, and under conduction of random perturbations. INFORMATICS PROVISION OF SIGHT INFLUENCE MUSCLE ACTIVITIES OF TRUNK AND LOWER LEG DURING DYNAMIC BALANCE CONTROL

LEE, J., WON, M., KIM, S.

Daegu University

Introduction The purpose of this study was to investigate the changes of electromyogram activity of trunk and lower leg muscles during dynamic balance control in 20 healthy adult subjects when various experimental visual conditions were applied. Methods Surfact electromyography system was used for recording of any signals produced by muscles. Muscle activity was recorded from muscles, of which left and right sides of rectus abdominis, external obliques, longissimus thoracis, multifidus, vastus medialis, biceps femoris, gastrocnemius, and tibialis anterior, and then normalized as percentage of maximum voluntary isometric contraction. All data obtained from experiment were analyzed using SPSS ver. 20.0, and TWOWAY analysis of variance were used to determine statistical significance between two factors (3 visual conditions x 2 leg conditions). Statistical significance levels were set at alpha = .05. Results There were significant different in biceps femoris and external obliques muscle's activities between right and left leg, showing more prominent reduction in left leg when blind vision condition was given. Significantly higher muscle activities were shown in both sides of multifidus ($p<.05$), vastus medialis ($p<.001$), tibialis anterior ($p<.001$) and gastrocnemius medialis ($p<.05$) with sighted vision and blanking vision compared to the condition of blind vision. Conclusions These results confirmed that muscle activity is prominently stimulated by visual information provision, and this implies that visual input may be a major factor for maintaining of the body's balance control.

LOCAL STABILITY AND KINEMATIC VARIABILITY OF WALKING VS. POLE WALKING AT DIFFERENT SPEEDS

ZOFFOLI, L., LUCERTINI, F., FEDERICI, A., DITROILO, M.

University of Urbino Carlo Bo

INTRODUCTION During walking (W) the body balance is maintained by muscle tone adjustments (Rose et al., 2006). Previous research reported that the use of poles can improve W stability (Jacobson et al., 1997); however, there are no direct dynamic stability comparisons between W and pole walking (PW). Accordingly, the present study aimed to compare both the dynamic stability and the variability of kinematic parameters during W and PW at different speeds. METHODS 21 adults were enrolled. 2 accelerometers were secured at C7 and S2 level. 3 bouts of 1 min each of W and PW were performed respectively at 60, 80 and 100% of the walk-to-run preferred transition speed (i.e. PTS-60, PTS-80 and PTS-100). Medio-lateral (ML), vertical (VT) and anterior-posterior (AP) accelerations were collected over 40 strides per trial. Stride time median absolute deviation (STV) was calculated as measure of gait cadence control, and the stride-to-stride variability (SSV) was quantified by the median of the point-by-point median absolute deviations of the cubic spline interpolated (101 points) stride pool for each accelerometer axis. The dynamic stability was assessed by maximum Lyapunov exponents (LE) for each accelerometer data pool (LE-C7 and LE-S2) and spatial direction (LE-ML, LE-AP, LE-VT). The speed and type (W or PW) effects on the calculated parameters were tested by generalized estimating equations and pairwise contrasts with Holm correction for multiple comparisons. RESULTS W and PW (all speeds) yielded similar STV, while PW resulted in lower LE-C7 than W ($p<.01$ at all speeds). Compared to W, at C7 level PW increased SSV-ML ($p<.01$ at PTS-80 and PTS-100) and reduced both LE-AP ($p<.01$ at PTS-60 and PTS-100) and LE-ML ($p<.01$ at all speeds). Speed increments decreased STV in W ($p<.01$) and PW ($p<.05$), LE-ML and LE-C7 (W only – all $p<.05$). Higher speeds increased SSV-ML in PW (all $p<.05$), SSV-AP in W (all $p<.01$) and SSV-VT in both W and PW (all $p<.01$). DISCUSSION Poles use improves LE at the shoulders level despite the corresponding increments in SSV. Conversely, W and PW show similar LE and SSV at the sacrum level. LE, SSV and the required control of the gait cadence generally increase at high speeds, but LE was speed-independent during PW. These findings suggest that walkers may benefit from using poles while exercising because of the lower LE, especially at those speeds where LE is higher during W. REFERENCES Rose J, Gamble JG. Invited symposia**IS-BN09 BIOMECHANICAL AND PHYSIOLOGICAL ASPECTS OF INCLINED WALKING****BIOMECHANICAL AND PHYSIOLOGICAL ISSUES OF INCLINED WALKING , RUNNING AND SKIPPING.**

MINETTI, A.

University of Milan

Literature regarding human locomotion on gradients classically focused on walking and running (at Earth gravity). Within pendulum-like gaits, walking with poles (sometimes referred to as Nordic Walking) recently expanded the ancient Alpenstock (single pole) concept and added comfort to mountain trekking, making humans go back to quadrupedalism. That motion pattern shares some biomechanics with the skating technique of cross-country skiing, which is also meant to work on gradients. Among bouncing gaits, 'skipping' (or bipedal 'gallop') and hopping have been more recently studied, the first one being used by joyful kids and by adults during stairs descending and cornering, the two of them having relevance for space exploration at different gravity. Although some important aspects remain a mys-

ter, the economy and biomechanics of gradient walking and running are quite well established. For instance, the partitioning between positive and negative mechanical external works, combined with muscle efficiency for concentric and eccentric activity, explained the metabolic optimum gradient of walking and running (Minetti et al. 1993, 1994). The other two gaits, mentioned above, represent an almost uncharted territory, particularly when adopted on gradients. Walking with poles, despite the gain in comfort, is associated to a higher metabolic cost than normal walking, particularly at level and negative slopes. Mechanical analysis of the dynamics of body centre of mass shows, though, an increased exchange between potential and kinetic energies, with the latter displaying a smoother time course as an effect of poles. Other influences could regard the trajectory of the centre of pressure and the moment that trunk muscles have to generate to balance the upper body in uneven, inclined terrains. Metabolic experiments on level walking, running and skipping at simulated Lunar gravity revealed that the cost of transport is very similar for all gaits (about 1.9 J/kg/m) and almost speed independent (hopping is metabolically impractical on Earth, but becomes the most economic gait on the Moon, Pavei et al. 2015). Gradient skipping has already been studied at Earth gravity, showing a monotonical decrease in cost at steeper downhill gradients (Minetti et al 2012), but only preliminary data is available at Moon gravity. The study of a variety of gaits at different gravity levels seems to offer potential insights to better understand the mechanical and metabolic determinants of level and gradient locomotion on Earth. INFLUENCE OF TENDON COMPLIANCE ON MUSCLE-TENDON INTERACTION DURING INCLINED WALKING AND STAIR DESCENT

ALBRACHT, K.

German Sport University

Influence of tendon compliance on muscle-tendon interaction during inclined walking and stair descent It is well accepted that tendon mechanical properties influence the function of the entire muscle-tendon unit. Those properties do not only affect force transmission but also have an important implication on energy storage and recovery. Additionally, the mechanical properties of the tendons are essential for the function of muscles during locomotion as they are acting in-series. The compliance of the tendon and aponeurosis allows an independent behavior of the muscle fascicles enabling those to contract at different shortening velocities than the entire muscle-tendon unit [1]. Studies with hopping wallabies or running turkeys, where tendon force and muscle fascicles length could be directly measured, gave evidence, that during steady state hopping and running most of the positive work done by the entire muscle-tendon unit comes from the recoil of the tendon and, that muscle fascicles change length only marginally [2, 3]. Metabolic energy is still required to generate muscle force, needed to operate tendons as springs. In contrast to the conservation of energy during steady state running, muscle-tendon units must have the ability to produce and absorb energy during walking on gradients or on stairs [1, 3, 4]. Energy absorption is generally realized by active lengthening of muscle fascicles, but they are particularly susceptible to damage when active lengthened [4, 5]. It was shown in animal studies that, the rate of fascicle lengthening can be reduced if the rapid stretch applied to the muscle-tendon unit can first be taken up by lengthening of the tendon [1, 6]. Ultrasonography provides the possibility to directly observe human muscle and tendon behavior during different locomotor activities *in vivo* [7-10]. Thus, this presentation will summarize current knowledge of human triceps surae muscle-tendon function during tasks that require energy generation or absorption e.g., locomotion on gradients or stairs and, will attempt to discuss the functional consequences of altered muscle-tendon properties due to training, ageing or injury. JOINT LOADING IN SLOPED WALKING COVERING DIVERSE SETTINGS

SCHWAMEDER, H., ALEXANDER, N.

University of Salzburg

Walking on sloped surfaces has been shown to be a challenging task for the locomotor system and requires specific modifications during gait. Swing limb trajectories, foot placement and other gait parameters like step length, step frequency and step width have to be adjusted for safe toe clearance and joint loading control (Prentice et al., 2004). Research groups analyzed the effect of sloped walking on postural adaptations (McIntosh et al., 2006), muscle activity (Franz and Kram, 2012; Lay et al., 2007), joint kinematics and joint kinetics (Lay et al., 2006) and joint loading (Schwameder et al., 2005) and found substantial adaptations when walking on sloped surfaces compared to level walking. In downhill walking joint moments at the ankle, knee and hip are affected by inclination with knee extension moments showing large increases relative to increased downward inclination (Lay et al., 2006). During uphill walking an increased hip extensor moment occurs with increasing inclination (Lay et al., 2006). The challenges of sloped walking are even more pronounced during hiking and mountaineering and specifically in patients with lower extremity injuries or amputees. Several studies have been executed by the authors' research group in order to specifically investigate the effect of the gradient in uphill and downhill walking in diverse settings. Beside young and healthy males and females also obese children and youth, ACL-patients and amputees have been studied. The participants walked on a ramp (6 m x 1.5 m) with two imbedded force plates, both in self-selected and pre-set speed conditions at different inclinations up to +/- 18°. Kinematics was measured using an eight camera Vicon system. Muscle activity of selected lower limb muscles was measured. Inverse dynamics approaches based on the musculo-skeletal modelling software AnyBody – validated for sloped walking (Alexander & Schwameder, 2015) – were used to calculate joint forces (Alexander & Schwameder, 2016a) and muscle forces (Alexander & Schwameder, 2016b). Furthermore, the aspects of interest were gait parameters (step length, step frequency, step width), joint kinematics, joint kinetics, lower extremity muscle activity, joint forces and muscle forces with respect to laterality, functional issues and recommendations for training regimes and rehabilitation programs for the several groups investigated in the studies. MAXIMAL VOLUNTARY STRENGTH AND RATE OF FORCE DEVELOPMENT BEFORE AND 6 MONTHS AFTER TOTAL HIP ARTHROPLASTY

FRIESENBICHLER, B., CASARTELLI, N.C., ITEM-GLATTHORN, J.F., WELLAUER, V., FERGUSON, S.J., MAFFIULETTI, N.A.

Schulthess Clinic

Introduction Patients suffering from hip osteoarthritis (OA) and concomitant hip pain show compensatory gait patterns, which may lead to asymmetries in lower extremity muscle function. Besides maximal voluntary contraction (MVC) strength, the rate at which force is developed (RFD) is highly important during daily-life situations related to balance, such as fall prevention. It is however unknown whether RFD recovers similarly to MVC strength asymmetries after total hip arthroplasty (THA). The aim of this study was to investigate the bilateral asymmetries in MVC strength and RFD for hip and knee muscles in patients with symptomatic hip OA before and 6 months after THA. **Methods** Twenty-one patients (65 ± 5 yrs, 174 ± 8 cm, 77 ± 14 kg, 9 women) with unilateral primary hip OA were tested before and 6 months after THA. Hip flexion, extension, abduction and adduction as well as knee flexion and extension MVC strength and RFD200 (i.e., the average rate of force developed from contraction onset to 200 ms thereafter) were evaluated in isometric conditions. 2-way repeated measures ANOVAs ($\alpha = 0.05$) were used to compare data between the involved and uninvolved limbs before and after surgery. **Results** Compared to the uninvolved limb, pre-operative MVC strength of the involved limb was significantly lower for hip flexion (-16%), hip extension (-13%) and knee extension (-11%). Similarly, pre-operative RFD200 was significantly lower for hip flexion (-16%), hip extension (-20%), hip abduction (-11%), hip adduction (-12%) and knee extension (-17%). Six months after surgery, no significant asymmetries remained, except of hip flexion MVC strength (-12%). **Discussion** Patients with symptomatic hip OA displayed considerable asymmetries in both MVC strength and RFD200 for both hip and knee muscle groups before surgery. RFD200 corresponded to MVC strength findings and in addition showed asymmetries in hip abductor and adductor muscles. As RFD is considered to be influenced by neural factors (Aagaard et al., 2002), we assume that patients with hip OA have a reduced neural drive, which may have a larger impact on certain muscle groups (hip abductors and adductors) compared to muscular factors. Most asymmetries resolved 6 months after surgery, while hip flexion MVC strength remained lower in the involved limb, possibly due to the surgical procedure (minimally invasive anterior approach). RFD asymmetries before surgery may put hip OA patients at a higher risk of falling and emphasize the importance of preventive strength training, predominantly for muscles crossing the hip and knee joints. **References** Aagaard P, Simonsen EB, Andersen JL, Magnusson P, Dyrhe-Poulsen P. CITIUS-FORTIUS? DOES MUSCLE STRENGTH IMPAIRMENT PREDICT RUNNING PERFORMANCE IN ATHLETES WITH POLIOMYELITIS?

BECKMAN, E.M., CONNICK, M.J., BUKHALA, P., TWEEDY, S.M.

University of Queensland

Introduction: Classification in Paralympic Sport aims to minimise the impact of impairment on the outcome of competition. Impaired muscle strength is an eligible impairment type in Paralympic Athletics and may result from range of health conditions, including poliomyelitis. To allow athletes who experience similar degrees of activity limitation as a result of their strength impairment to be placed in the same class, research is required to determine the relationship between muscle strength and running performance. This study aimed to investigate muscle strength impairments in athletes with polio when compared to non-disabled athletes. **Methods:** Fifteen athletes with polio were assessed in Nairobi, Kenya. A non-disabled sample of 28 athletes (NDA), were assessed in Brisbane, Australia. Athletes performed isometric strength tests (lower limb extension and isolated plantar flexion), and a running performance test (maximal 60m sprint). Sub-group analysis was performed to compare athletes with polio who were able to run with a definitive flight phase, to athletes who were not able to achieve a flight phase during their running gait, on measures of strength and performance. **Results:** Independent t-tests showed significant differences between groups in running performance and strength. Non-disabled athletes were faster over 60m with a mean (SD) of 8.39 seconds (0.54) when compared to athletes with Polio who ran 60m in a mean (SD) of 16.01 seconds (4.34). Pearson's correlations showed weak relationships between lower limb extension strength and running performance in NDA ($r=0.16$), compared to a strong, significant relationship in runners with Polio ($r= 0.67$). Significant differences in sprint times were seen in athletes who could achieve a running gait compared to those who could not, and significant differences in the combined strength of the leg extension and plantarflexion tests were seen between runners and non-runners. **Conclusions:** The results of this study indicate that as impairments to muscle strength increase in severity, running performance is more affected. The results also give a preliminary insight to the amount of muscle strength that is required in the lower limbs to achieve a running gait that includes a flight phase. While proximal and distal muscle strength individually did not predict the ability to run in this sample, severe impairments at the proximal and distal level combined did have an impact. This study provides preliminary evidence for the strength of association between lower limb strength and running performance and a key step towards evidence-based systems of classification.

ASSOCIATION OF PHYSICAL ACTIVITY AND FITNESS WITH SYMPTOMS AND IMPACT OF FIBROMYALGIA IN FEMALE PATIENTS.

SEGURA-JIMÉNEZ, V., ESTÉVEZ-LÓPEZ, F., ÁLVAREZ-GALLARDO, I.C., SORIANO-MALDONADO, A., BORGES-COSIC, M., HERRADOR-COLMENERO, M., RUIZ, J.R., APARICIO, V.A., DELGADO-FERNÁNDEZ, M.

University of Cadiz

Segura-Jiménez, V.1, Estévez-López, F.2, Álvarez-Gallardo, I.C.2, Soriano-Maldonado, A.2, Borges-Cosic, M.2, Herrador-Colmenero, M.2, Ruiz, J.R.2, Aparicio, V.A.2, Delgado-Fernández, M.2. 1: FES (Cádiz, Spain) 2: FSC (Granada, Spain). **Introduction** Maintaining appropriate physical fitness (PF) levels through exercise training in patients with fibromyalgia has shown to be a beneficial treatment, however, these patients seem susceptible to an inactive lifestyle (Segura-Jiménez et al., 2015). It is of interest to investigate whether objectively measured physical activity (PA) and PF are independently and jointly associated with fibromyalgia symptomatology. **Methods** This cross-sectional study comprised 386 women with fibromyalgia aged 51.5 ± 7.6 years. PA was measured with triaxial accelerometry and PF with the

Senior Fitness Test. We used the Short-Form health survey-36 pain sub-scale and the Multidimensional Fatigue Inventory to assess pain and multiple dimensions of fatigue, respectively. The impact of fibromyalgia was studied with the Revised Fibromyalgia Impact Questionnaire. Results A stepwise regression model showed that diverse fitness components and light and vigorous PA were independently associated with pain, fatigue and the impact of fibromyalgia (R^2 between 0.15 and 0.29, all $P < 0.05$). Both, total PA and global PF showed an independent association with all the studied variables (R^2 between 0.15 and 0.29, all $P < 0.05$), except with mental fatigue. The associations between total PA and symptoms were weaker than those observed between global PF and symptoms. Overall, unfit patients with low total PA showed a worse profile than fit patients with high PA (all, $P < 0.01$). Discussion To our knowledge, we showed for the first time that higher light and vigorous PA and diverse PF components are independently associated with lower pain, fatigue and the overall impact of the disease in women with fibromyalgia. Patients who were fit and physically active displayed a better profile than those who were unfit and physically inactive. Furthermore, patients unfit should be physically active to avoid a greater deleterious impact. This is consistent with previous literature, which showed that physically active women with fibromyalgia have increased ability to modulate their pain than those physically inactive (Ellingson et al., 2012). We cannot establish causal relationships: physical inactivity and low PF might lead to fatigue and pain, but equally, fibromyalgia could accentuate fatigue and have detrimental effects on aerobic and muscle performance. Reluctant to conclude on causality, our results seem to encourage the inclusion of both regular PA as well as maintaining adequate PF levels as a major part of fibromyalgia women's lifestyle. EFFECTS OF PROPRIOCEPTIVE EXERCISES ON RHEUMATOID ARTHRITIS POSTMENOPAUSAL WOMEN

ALEIXO, P.1, VAZ PATTO, J.2, ABRANTES, J.1

(1) MovLab/ULHT (Lisbon, Portugal); (2) IPR (Lisbon, Portugal)

Introduction Rheumatoid arthritis (RA) may lead to damage joints and the occurrence of cachexia. Women are more predispose than men to develop RA and the peak incidence coincides with menopause. A lower ankle moment of force during gait was associated to falls in elderly (Lee & Kerrigan, 1999). RA patients showed lower ankle power peak (APP) and ankle moment of force peak (AMP) during gait (Barn et al, 2013; Weiss et al, 2008). A systematic review (Sherrington et al, 2008) provided strong evidence that proprioceptive exercises are effective to reduce falls in elderly. Proprioceptive exercises also enhanced gait biomechanical variables in elderly (Shin & An, 2014). Present study aimed to assess the effects of proprioceptive exercises on AMP and APP during gait and lower limb muscle mass (LLMM) of RA postmenopausal women. Methods Prospective, controlled but nonrandomized trial. 26 RA postmenopausal women assigned to exercise group (EG; n=14) or placebo exercise group (PEG; n=12). In EG was performed a 12-week proprioceptive exercises program (3 individualized sessions/week; 30 minutes/session). In PEG was performed a 12-week program of stretching exercises for trunk and upper limbs (1 individualized session every two weeks; 30 minutes/session). LLMM was assessed by bioelectrical impedance analysis (InBody 720). A three-dimensional motion analysis system (Vicon®/Motion Capture MX System; 9 cameras; 200 Hz) synchronized with a force plate (AMTI BP400600-200; 1000 Hz) were used to analyse gait. The PlugInGait biomechanical model determined mechanical segments and joint centres, which were based in anthropometric measurements and placement of reflective markers. Subjects walked barefoot at natural and self-selected speed performing 7 valid trials for the contact of each foot on force plate. Results After program, EG showed higher APP (2.33 W/kg vs 2.60 W/kg; 12%, $p < 0.001$); no changes were observed in AMP (1.12 Nm/kg vs 1.16 Nm/kg) and LLMM (6.00 kg vs 6.01 kg). PEG showed no differences after program (APP - 2.27 W/kg vs 2.27 W/kg; AMP - 1.08 Nm/kg vs 1.09 Nm/kg; LLMM - 5.70 kg vs 5.80 kg). Discussion A 12-week individualized proprioceptive exercises program enhanced ankle power of RAPW during the propulsive phase of gait; however had no evident statistical effects on LLMM and AMP. According to these results, we suggest that proprioception and motor control will be behind of the better performance during the propulsive phase of the gait, which may have been enhanced after the proprioceptive exercise program. WAND EXERCISE TO IMPROVE PHYSICAL FUNCTION AND DECREASE PAIN IN PERSONS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE EXPERIMENTAL STUDY

NUALNETR, N.

Khon Kaen University

Introduction It is well known that exercises are essential for persons with rheumatoid arthritis (RA). Presently, wand exercise is popular among community-dwellers in Thailand. There were reports on the beneficial effects of wand exercise on cardiovascular health, muscle strength, range of motion and flexibility in adults. However, there was no study in persons with RA. This study aimed to evaluate the effects of a wand exercise program on physical function and pain in persons with RA. Methods Forty-five persons with RA in low or moderate severity level (average age 57.3 years) participated in a wand exercise program of 20 minutes/day, 3 days/week for 6 weeks. Outcome measures were physical function and pain assessed by the Health Assessment Questionnaire and Visual Analog Scale, respectively. Before exercising, the participants underwent pre-exercise assessment. They were reassessed immediately after the completion of the 6-week program and at week 9 of the follow-up period. Wilcoxon Signed Rank test and paired t-test were applied to analyze the results of physical function and pain, respectively. A value of $p < 0.05$ was used to decide the significance for all analyses. Results When compared with baseline, assessments at weeks 6 and 9 revealed that the wand exercise significantly improved physical function and decreased pain of the participants ($p < 0.001$, median difference of physical function = -0.5 points, mean difference of pain level = -20.1 mm). No significant differences in both outcome measures were found when compared between the scores obtained from the assessments at weeks 6 and 9. Discussion Wand exercise is a combination of flexibility, balance, endurance and diaphragmatic breathing exercises (Wichitsranoi et al., 2011). It emphasizes smooth movements with full range of motion of the trunk and extremities (Peungsawan et al., 2008) which should help increase blood circulation. Therefore, wand exercise was possible to improve physical function and decrease pain in persons with RA, as shown in this study. The current finding was consistent with that reported in previous studies (Baillet et al., 2009; Neuberger et al., 2007). To reveal further benefits of wand exercise in persons with RA, future studies with a comparison group and/or longitudinal design are recommended. IMPROVED PHYSICAL ACTIVITY LEVEL IN CANCER PATIENTS PARTICIPATING IN A 12-MONTH LIFESTYLE INTERVENTION WHILE UNDERGOING PALLIATIVE CHEMOTHERAPY

VASSBAKK-BROVOLD, K.1,2, KERSTEN, C.1, FEGRAN, L.1,2, LIAN, H.1, MJÅLAND, O.1, MJÅLAND, S.1, SEILER, S.2, BERNTSEN, S.2
1) Southern Hospital Trust; 2) University of Agder

Introduction Despite a growing body of evidence presenting associations between physical activity (PA) and improvements in patient-reported outcomes, recurrence and mortality in cancer patients, few cancer patients are able to meet the American Cancer Society PA guidelines of >150 min.wk⁻¹ of moderate PA. Previous PA interventions in cancer patients commonly offer a one-size fits all-approach in selected samples of the fittest and most motivated patients; often after the completion of adjuvant treatment. Few studies have offered PA interventions in cancer patients undergoing oncologic treatment, specifically with palliative intent. The objective of the present study was to describe self-reported PA changes in cancer patients participating in a comprehensive lifestyle intervention while undergoing chemotherapy with curative or palliative intent. **Methods** The present study was part of a 12-month individualized lifestyle intervention focusing on diet, PA, stress management and smoking cessation in 100 cancer patients during chemotherapy. Participants completed the short form of the International Physical Activity Questionnaire (IPAQ-sf) during monthly counseled sessions with a lifestyle supervisor at the cancer center. End of study (EOS) versus baseline changes in moderate-to-vigorous intensity PA (MVPA) were reported as min.wk⁻¹. Walking was included in MVPA. Results 59 of 100 participants (21 palliative) completed IPAQ-sf both at baseline and EOS. A non-significant but higher level of self-reported MVPA was observed at baseline in curative (1027, 95% Confidence Interval 700, 1354 min.wk⁻¹) vs. palliative (900, 364, 1436 min.wk⁻¹) patients ($p = 0.197$). Self-reported MVPA in curative patients was relatively constant throughout the 12-month intervention. Opposing, palliative patients increased their PA levels to similar levels as curative patients after two months, before slowly decreasing at EOS. A linear regression model revealed significant pre-post differences in MVPA level between treatment intent groups ($p = 0.006$) and the PA developed significantly different in curative vs. palliative patients. **Discussion** Self-reported PA during a 12-month lifestyle intervention developed differently in curative vs. palliative patients. Our findings show that participating in a lifestyle intervention may affect self-reported PA in palliative but not curative patients. These findings should be considered when implementing PA interventions in cancer patients with different treatment intents. Further, our findings are promising with regard to future interventions in palliative cancer patients.

IS-SH09 INCLUSIVE PHYSICAL ACTIVITY IN PHYSICAL EDUCATION, SPORT, AND REHABILITATION

THE ROLE OF REHABILITATION TO ENHANCE AN ACTIVE LIFESTYLE & SPORT PARTICIPATION IN PEOPLE WITH A DISABILITY

DE GROOT, S., VALENT, L., HOEKSTRA, F., VAN DER WOUDE, L.

Reade

Rehabilitation professionals should play a role in assisting people with disability to enroll into physical activities and sports to prevent long-term deconditioning and health problems. Sports is an integral part of Dutch rehabilitation treatment protocols. In a multi-center study, people with spinal cord injury (N=158) indicated at discharge of inpatient rehabilitation that they tried handcycling (77%), archery (28%), wheelchair basketball (25%), table tennis (18%), wheelchair tennis (11%) or other sports. One year after discharge, 98% of this group (N=153) indicated to have handcycled in the past three months and 37% indicated to have participated in another sport than handcycling, with fitness (14%) as the most mentioned sport. Prevention of health problems due to inactivity has to continue after discharge of rehabilitation. Therefore, a sports desk is implemented in Dutch rehabilitation practice. Persons with a disability get a personal advice and support by a sports and movement consultant using a motivational interviewing approach. Furthermore, ex-patients are stimulated to participate in the HandbikeBattle, a mountain time trial among teams from 11 Dutch rehabilitation centers in the Alps of Austria. The main goal of the HandbikeBattle is to stimulate handbike training and as a result to become physically and mentally fit. Multi-center prospective cohort studies investigate these active lifestyle and sports stimulation programs in all participating rehabilitation centers. The Dutch association of physiatrists has initiated an official working group on 'Exercise and sports' to further implement methodologies for active lifestyle and sports stimulation.

PROMOTING PARTICIPATION IN PHYSICAL ACTIVITIES FOR CHILDREN WITH DISABILITIES

KLAVINA, A.

Latvian Academy of Sport Education

Physical education (PE) and sport is considered as a growing social phenomenon that makes an important contribution to inclusion. However, ensuring that students with disabilities benefit fully from learning and social opportunities available through PE and sport programs remains an important challenge. This presentation will focus on part of the large scale project outcomes investigating evidence-based strategies for promoting access to the participation in sport and physical education activities for children with disabilities. Several research outcomes have presented relation between the fundamental movement skills (FMS) proficiency and the time allocated to daily physical activities (Lin et al., 2005; Rimmer et al., 2007; Zwier et al., 2010). Furthermore, the relationship of FMS with physical activities can be understood through the International Classification of Functioning, Disability and Health (ICF) model for children and youth. In this study the body movement functions, physical skills and cognitive ability were presented as quantitative health indicators for participation in physical activities (WHO, 2007). The bi-directional relationship of ICF components suggests that targeting the movement functional and cognitive proficiency of children could generate positive effects on their physical activity engagement. Considering the impact of disability on movement functional and cognitive development and furthermore on physical activity participation, the interdisciplinary assessment package was developed and validated across four groups of children with different disabilities, n=116 (visual, physical, hearing and intellectual), including: (1) fundamental skill assessment (TGMD-2), (2) four physical skill assessments (strength, balance, flexibility and speed), and (3) physiological skill assessment including the three assessment packages to measure the postural stability and physical fitness condition parameters (e.g., muscle force, endurance and electromyographic response to muscle fatigue). The cognitive test pack-

age included the six subtests of the Vienna Test System. The outcomes of validation studies across the four disability groups will be presented during the session. ACCESSIBILITY IN SPRTS FACILITIES

KILPELÄ, N.

The Finnish Association of People with Physical Disabilities

The presentation is a conclusion of accessibility work of the Finnish Sports Association of Persons with Disabilities funded by the Finnish Ministry of Education and Culture and executed in co-operation with disability organizations during 2009–2014. The purposes of the projects were to evaluate accessibility of sports facilities, collect sports specific accessibility information and develop existing accessibility information as well as accessibility audit methods in sports facilities. The projects included an analysis of existing guidebooks as well as an internet survey. Sports specific guidelines for accessibility auditors were developed and 14 accessibility audits in training centres (sports academies) were put into practice. Both the social model of disability and UN Convention on the Rights of Persons with Disabilities emphasize accessible environment. The analysis of guidebooks revealed the inexistence of sports specific guidelines among accessibility information. Accessibility must be observed comprehensively as an integral concept related to moving, seeing, hearing, and understanding. There is a need for co-operation between the disability sport actors, disability advocates, accessibility specialists, architects, designers, builders and developers. The objective accessibility audit method was a useful tool when supplemented with disability sports specific information and used by trained auditors.

OP-PM66 Sports Medicine: Heart Rate Variability

MORNINGNESS/EVENINGNESS EFFECTS ON AUTONOMIC FUNCTION DURING A HIGH INTENSITY INTERVAL TRAINING PROTOCOL IN SOCCER PLAYERS. A RANDOMIZED CROSS-OVER STUDY

BONATO, M., VITALE, A., MANCUSO, G., MERATI, G., LA TORRE, A.

Università degli Studi di Milano

Introduction The 4x4 min of interval running proposed by Helgerud et al., (2001) is one of the widely used methods that have been demonstrated to improve soccer performance. For this reason, monitoring the effects of this type of training could provide useful information to make evidence based decisions on appropriate loading schemes to enhance team performance and reduce injuries. Therefore, the aim of this study was to assess the acute effects on heart rate variability (HRV) of this training protocol performed at different times of the day (8.00 am vs 8.00 pm). Methods In a cross-sectional study, 30 male recreational soccer players, age 20±2 y-o, were randomized to morning (MG=15) or evening group (EG=15). Subjects performed an aerobic interval training protocol consisted of four times 4 min at 90–95% of maximal heart rate (assessed during a Yo-Yo IR1 test) with a 3-min jog in between. HRV was measured at REST, PRE, POST-12h and POST-24h the 4x4 protocol. HR variability indexes in time, Root Mean Square of the Successive Differences (RMSSD) and the standard deviation of NN intervals (SDNN), frequency (Low Frequencies, between 0.04 and 0.15 Hz [LF], and High Frequency, between 0.15 and 0.40 Hz [HF], in normalized unit) were calculated. Results One-way ANOVA showed that both morning/evening aerobic interval training protocol significantly increased the parasympathetic cardiac tone POST-12h ($p<0.05$) which returns to baseline level POST-24h. Un-paired t-test detected significant difference in PRE aerobic training in LnRMSS ($p=0.049$), LnSDNN ($p=0.043$), HF n.u. ($p=0.021$), showing that in evening conditions subjects have an increased parasympathetic activity. In POST-12h subjects that trained during the evening have an increased LnRMSS ($p=0.043$), LnSDNN ($p=0.032$), HF n.u. ($p=0.024$), maybe due to a reduced recovery. No differences in POST-24h both in sympathetic and parasympathetic activity were detected. Discussion The 4x4 protocol seems to influence the parasympathetic tone in the same way both in morning and evening conditions. On the other hand, in PRE conditions people that train in the evening showed an increased parasympathetic cardiac tone. Because soccer players have often to train twice a day during the season, with morning and evening training sessions, monitoring HRV is a useful and non-invasive method to detect the effects of high intensity interval training, with the aim to facilitate a more efficient planning and manipulation of training sessions. USEFULNESS OF MONITORING RESTING HEART RATE VARIABILITY DURING A FOUR-WEEK PRE-SEASON PREPARATION PERIOD IN INTERMITTENT SPORT ATHLETES

SCHNEIDER, C., SCHMIDT, A., WIEWELHOVE, T., RAEDER, C., FERRAUTI, A.

Ruhr-University Bochum

Introduction Measuring heart rate (HR) variability (HRV) is suggested to be of high value in monitoring training by offering insights into mechanisms of cardiac autonomic nervous system activity and modulation. Aim of the study was to evaluate whether HRV monitoring is able to display fatigue and recovery dynamics as well as performance adaptations during four-weeks of high-intensity interval training. Methods Twelve intermittent sport athletes ($\text{VO}_{2\text{peak}} 55.6 \pm 4.4 \text{ ml/min/kg}$) completed a periodised four-week high intensity interval training program based on three sessions per week. Maximal and submaximal endurance performance capacity was conducted using an incremental treadmill test prior to (baseline) as well as two (post 1) and nine days (post 2) following the training cycle. Overall recovery was assessed using the short recovery stress scale (SRSS) at the beginning of both training and testing sessions. HRV was measured daily upon awakening for six minutes under supine conditions two weeks preceding, during and two weeks following the intervention period. HRV was calculated using a rolling seven-day average. Data were analysed for practical relevance using magnitude-based

inferences on both group and individual level. Results Maximal running performance was likely to most likely increased at post 1 and post 2 (Cohen's $d=0.20-0.41$), whereas submaximal capacity was possibly increased at post 2 ($d=0.21-0.23$). Overall recovery (SRSS) was likely to most likely decreased in training weeks 1 and 3 ($d=1.12-1.25$) compared to baseline. There were no relevant HRV changes between the tests or during the training period, as well as no relevant correlations between changes in HRV and performance. Single-case analysis displayed substantially diverging HRV kinetics, e.g. opposed trends in three athletes with similar above-average performance enhancements. Discussion HRV monitoring based on daily resting measures and analysis of rolling seven-day averages was neither able to track the observed alterations in fatigue and recovery, nor the performance adaptations on group level. When using single-case research methods, HRV monitoring seems to provide valuable information on individual responses and adaptations, which might enable program adjustments for further training optimization and individualization. However, the enormous amount of effort required, seems not to be justifiable regarding the possible benefits. Therefore, monitoring HRV in comparable settings using currently established methods is not recommended. References Buchheit M (2014) Front Physiol, 5(73). Hopkins WG (2004) Sportscience, 8, 1-7. HYPOXIC HIGH-INTENSITY INTERVAL EXERCISE ALTERS HEART RATE VARIABILITY AND SUBSTRATE OXIDATION DURING RECOVERY

LUBBEN, K., BLAIR, J., ADEBOYE, A., KELLY, L., BASSET, F.A.

Memorial University

INTRODUCTION The beat-by-beat change in heart rate, the so-called heart rate variability (HRV), is dependent on the cross-talk between sympathetic and parasympathetic nervous systems (SNS and PNS) (Yamamoto et al., 1996). HRV is affected by several factors such as exercise intensity, training status, health condition, gender, and environmental conditions, to name a few (Darr et al., 1988). However, no study has examined the cumulative effect of exercise and hypoxia on the sympathovagal balance and its potential association with the change in substrate partitioning during recovery. The purpose of this study was, therefore, to examine the effect of hypoxic exercise on HRV, and its association with change in substrate oxidation. **METHODS** Eight active healthy males (age: 31 ± 11 years; height: 180 ± 7 cm; weight: 83 ± 8 kg; BMI: 25 ± 1 kg•m $^{-2}$; $\dot{V}O_{2\text{max}}$: 4.4 ± 0.6 L/min) were subjected to a 45-minute high-intensity interval (HII) cycling protocol in normoxia ($FiO_2 = 0.2093$) and hypoxia ($FiO_2 = 0.15$), respectively. In addition, a basal metabolic rate (BMR) and three 30-minute post-exercise metabolic rates over a 3-hour period were recorded in normoxia. Maximal oxygen uptake and peak power output were determined using a ramp cycling test in normoxia. HII consisted of alternating 3 minutes at 70% and 3 minutes at 35% PPO in both conditions. ECG, RPE, and blood lactate were recorded during exercise while substrates oxidation was measured pre- and post-exercise along with ECG and blood lactate. **RESULTS** During exercise, RPE was higher ($p < 0.01$) and lactate increased ($p = 0.001$) at each point of time in hypoxia, with no change in normoxia. After hypoxic exercise, SNS/PNS ratio was significantly higher ($p < 0.01$) and significantly decreased through time in both conditions ($p < 0.01$). In addition, a significant interaction between time and conditions ($p < 0.02$) showed a decrease in lactate concentration through time post-hypoxic exercise. **DISCUSSION** The findings showed that a single bout of hypoxic exercise alters the autonomic nervous system activity post-exercise along with shifting substrate partitioning from glycolytic to lipolytic energy production. The significant decrease in blood lactate concentration post-hypoxic exercise supports the notion that hypoxic HII induces a greater muscle glycogen depletion leading to increased fat oxidation to sustain glycogenesis and gluconeogenesis to maintain blood glucose level during recovery. **REFERENCES** Darr KC, Bassett DR, Morgan BJ, Thomas DP. CAN IANT BE DETERMINED BY HEART RATE VARIABILITY IN OVERWEIGHT SUBJECTS?

REER, R.

University of Hamburg

Introduction Numerous studies reported that the heart rate variability (HRV) may be used to determine the aerobic-anaerobic thresholds (IANT) in healthy trained participants (1,2,3). The aim of this study was to assess if the IANT may also be determined in overweight and obese subjects utilizing the non-linear response of HRV. Methods 28 overweight and obese participants (age: 38.5 ± 13.1 yrs; Wt: 96.4 ± 16.7 kg; BMI: 30.9 ± 4.4 kg•m $^{-2}$; %body fat: 29.2 ± 4.3 ; waist circumference: 107.8 ± 10.9 cm) completed a two stage incremental test on cycle ergometer followed by continuous performance test to determine and validate the lactate thresholds and IANT. The examination of individual HRV variables and associated HRV thresholds were determined via continuous 12-lead ECG monitoring and recordings. The agreement of resulting power output thresholds expressed in Watts (W) in the region of IANT and those determined from HRV recordings were ascertained via Bland-Altman plots and correlation analysis. Results The calculated thresholds generated from HRV recordings were above those performed in IANT (W: 126 ± 30.7 ; utilizing the Pointcare Chart variability, SD1 of 144.8 ± 32.9 = standard deviation of the short-term RR interval variability of transverse axis; SD2 of 146.1 ± 30.5 = standard deviation of the long-term RR interval variability of longitudinal axis; SD1/SD2 ratio of 145.2 ± 27.8 ; SD1/HR ratio of 144.4 ± 32.2). The results revealed agreements in IANT determination that were confirmed via Bland-Altman Plots as well as significant correlation coefficients generated from the cycle ergometer power output (SD1 = 0.69; SD2 = 0.61; SD1/SD2 = 0.66; SD1/HR = 0.68). Discussion The results of this study yielded moderate to strong associations between HRV threshold data and results determined via IANT power output on cycle ergometer. In our overweight and obese participants, the response in HRV variability was present and possible only during the short-term analysis. References 1. PREDICTING MATCH OUTCOME USING WEEKLY HEART RATE VARIABILITY RECORDINGS

LEICHT, A.1, WOODS, C.1, SINCLAIR, W.1, BOWMAN, P.1,2

1: James Cook University (Townsville, Australia), 2: North Queensland Cowboys (Townsville, Australia)

Introduction Monitoring workloads, well-being and performance is common practice for elite athletes and coaches. However, the optimal measure to assist preparation for competition remains to be identified. Heart rate (HR) variability (HRV), a simple non-invasive measure of cardiac autonomic modulation, has attracted interest as a monitoring tool for elite sporting teams but its ability to predict performance has not been well established. The aim of this study was to examine whether weekly HRV assessments could predict match outcome for

elite, rugby league athletes. Methods Thirty-two athletes volunteered for this study and undertook weekly recordings of HR, regular exercise training and competitive matches during the 2014 National Rugby League season. Supine recordings of resting HR (5-mins) were obtained each week, ~4 days before competitive matches. All recordings were analysed for time- and frequency-domain, and non-linear measures of HRV using specialist software (Kubios v2.1). Match performance/outcome was documented as team win or loss. Between group differences for each HRV measure were established via independent t-tests for the main effect of match outcome. Binary logistic regression models were built to investigate the association between match outcome (response variable) and each HRV measure (explanatory variables). The most parsimonious model was identified using the "dredge" function within the MuMin package in the R statistical computing environment v3.1.3. Results Athletes exhibited a significantly greater, resting HR (61.8 ± 8.8 vs. 59.1 ± 8.4 bpm, $p < 0.01$) and short-term HRV (standard deviation of successive RR interval differences, 8.0 ± 3.7 vs. 7.2 ± 3.3 ms, $p < 0.05$) prior to wins. All other weekly HRV measures were similar prior to wins and losses. The following frequency-domain and non-linear measures of HRV were identified as significant ($p < 0.05$) independent predictors of match outcome: very low frequency (absolute units), and recurrence plot analysis (RPA) – mean diagonal line length and Shannon information Entropy of line length distribution. The most parsimonious model retained these three predictors (Akaike's information criterion delta weight of 0.014). Discussion Prior to successful match outcomes, elite rugby league athletes exhibited enhanced short-term HRV with specific frequency-domain and non-linear measures of HRV successfully predicting match outcome. Assessment of weekly HRV measures may provide prognostic indication of future success for team sport athletes. Future studies may clarify the significance of non-linear RPA and measures of HR complexity for sporting performance to assist coaches and athletes. Contact Anthony.Leicht@jcu.edu.au

OP-PM32 Cycling Tests

EFFECTS OF TRIAL DURATION ON ESTIMATES OF CRITICAL POWER AND TIME-TRIAL PREDICTION DURING FIELD CYCLING

GUMPENBEGER, M., HEIDER, S., NIMMERICHTER, A.

University of Applied Sciences Wiener Neustadt

Introduction The hyperbolic response between power and duration is characterised by an asymptote (critical power; CP), which theoretically represents the maximum rate of work that can be maintained for a very long time without fatigue and a finite amount of work that may be performed above CP (W'). Traditionally CP and W' are estimated from 3-5 constant power ergometer trials leading to exhaustion within 1-12 min. It has been shown that the range of duration can affect estimates of CP. Therefore, the aim of this study was to determine the effect of trial-duration on estimates of CP in field conditions. In addition, the accuracy of CP to predict 20-min time-trial power (TT20) was assessed. We hypothesised that different trial-duration result in similar CP estimates and accurately predict TT20. **Methods** Ten male endurance trained cyclists (mean \pm SD, age: 31.4 ± 5.8 years, body mass: 76.8 ± 6.0 kg, VO_{2max}: 60.0 ± 4.1 ml/kg/min) completed three maximal-effort sessions on flat roads, on a racing bike equipped with a mobile power-meter (SRM). To estimate CP, trials of 1, 4, and 10 min (CP1), and 2, 7, and 12 min (CP2) interspersed by 30 min, were performed during session one and two, respectively. During session three, the TT20 was conducted. CP1 and CP2 were modelled using the linear work/time relationship. In addition, a third set consisting all trials from 1-12 min (CP3) was used to estimate CP. Repeated measure ANOVA was used to compare CP and TT20 across the trials. The standard error of estimate (SEE) from linear regression analysis was used to assess prediction accuracy. **Results** There were no significant differences between CP1 (305 ± 38 W), CP2 (298 ± 35 W), CP3 (301 ± 35 W) and TT20 (317 ± 31 W) ($F_{3,7} = 3.1$; $p = 0.1$). Strong correlations were found between TT20 and CP (0.86 , 0.82 and 0.86 , all a $p < 0.001$ for CP1, CP2 and CP3, respectively). The SEE was 17 W, 19 W and 17 W for CP1, CP2 and CP3, respectively. **Discussion** In the present study no significant differences in CP were observed when estimated from different trial durations. Irrespective of trial duration, accuracy to predict TT20 was approximately 5%. In accordance with previous studies where TT20 was not significantly different to ventilatory and lactate thresholds, no significant differences were found with CP. This suggests, that TT20 can serve as a surrogate for different thresholds such as ventilatory and lactate thresholds or CP. From a practical point, the use of shorter trial durations does not affect estimates of CP.

TIME OF DAY DOES NOT INFLUENCE PACING AND PERFORMANCE IN A 4 KM CYCLING TIME TRIAL

ZADOW, E.

University of Tasmania

Introduction: Time of day has been shown to impact athletic performance with increases of 10% observed when competing between the hours of 1600 to 2000 h, or within an athlete's circadian peak window [1]. Physiological factors such as body temperature and hormonal responses display individual circadian rhythms and are believed to be associated with alterations in performance. These factors are also likely to influence the distribution of pace throughout an event, however, we are aware of only one study that has investigated the influence of time of day on pacing [2]. Therefore, the aims of the present study were to investigate the influence of time of day on pacing selection within a 4 km cycling time trial. **Methods:** Fourteen trained male cyclists (age: 38.9 ± 10.7 y, weight: 77 ± 9 kg, height: 181 ± 7 cm, VO_{2max}: 64.5 ± 8.0 ml.kg⁻¹.min⁻¹) performed five 4 km cycling TTs on their own bicycle fitted to a cycle trainer (KICKR: Wahoo Fitness, Atlanta, GA) over five different times of the day (0830, 1130, 1430, 1730 and 2030 h). All trials were completed in a randomised order with each trial separated by a minimum of two and a maximum of seven days. Pacing was assessed through the collection of power, cadence, heart rate and oxygen consumption at 1 km averages throughout each TT. Ratings of perceived exertion (RPE: 6-20) and effort (VAS: 0-10) were collected immediately post TT. Power, cadence, heart rate and oxygen consumption were analysed using two-way repeated measures analysis of variance (Time of Day x distance). RPE and effort were analysed using a repeated measures analysis of variance. **Results:** No differences in overall average power output, cadence and total time were observed between time trials performed at 0830, 1130, 1430, 1730 and 2030 h ($p > 0.05$). Average heart rate and oxygen consumption remained similar and showed no significant differences between trials ($p > 0.05$). No differences in pacing were observed between the 4 km time trials when performed at 0830, 1130, 1430, 1730 and 2030 h ($p > 0.05$). **Conclusion:** When assessed at 0830, 1130, 1430, 1730 and 2030 h, the time of day did not influence pacing and performance within a 4 km time trial. The findings from this study may have implications for the testing and monitoring of athletic performance using trials of a similar distance. **References** 1. Reilly T, Waterhouse J. EFFECT OF PEDAL RATE DURING TIME TRIAL ON OXYGEN UPTAKE KINETICS IN A SUBSEQUENT RUNNING TASK

WALDHUBER, F., NIMMERICHTER, A.

University of Applied Sciences Wiener Neustadt

Introduction Previous studies reported an increase in running time-to-exhaustion after 30 min cycling at a cadence of 75 rpm compared with 95 and 109 rpm (Vercruyssen et al. 2005). The aim of the present study was to analyze whether the pedal rate in cycling time trial affects parameters of oxygen uptake kinetics in a subsequent running task under laboratory conditions. **Methods** Ten male endurance trained subjects (mean \pm SD, age: 27.5 \pm 4.8y, body mass: 76.2 \pm 8.8kg, VO_{2max}: 62.1 \pm 6.0ml/kg/min) performed three laboratory trials. The subjects completed a graded exercise test (GXT) on a treadmill and two trials consisting of a time trial (360 kJ) and a running task. The time trials were conducted at a cadence of 60 and 90 rpm in the linear mode of the Lode Excalibur ergometer. Immediately after the time trials the subjects were asked to change into their running shoes and to complete a 6-min running task on the treadmill at an intensity of the respiratory compensation point obtained from the GXT. Oxygen uptake was measured breath-by-breath using a Cortex gas analyser. Nonlinear least square regression analyses were used to resolve the time constant, the amplitude and the time delay of the primary phase. A paired-samples t-test was used for statistical analyses. **Results** The time to complete the time trials were 1153 \pm 141s and 1201 \pm 179s at 60 and 90 rpm, respectively ($t(9) = -2.88$, $p = 0.018$). There were no significant differences between the 60 and 90 rpm for the time constant (31.3 \pm 6.8s vs. 33.3 \pm 5.8s; $t(9) = -2.1$, $p = 0.066$), the amplitude (2.59 \pm 0.37 L/min vs. 2.56 \pm 0.36 L/min; $t(9) = 0.82$, $p = 0.433$), the time delay (17.9 \pm 4.9s vs. 16.6 \pm 4.2s; $t(9) = 0.90$, $p = 0.391$) and the end-exercise oxygen consumption (4.29 \pm 0.56L/min vs. 4.28 \pm 0.63L/min) during the 6-min treadmill running task. **Discussion** The results of the present study support previous findings where improvements in power output and gross efficiency during cycling at 60 compared with 90 and 100 rpm have been reported (Nimmerichter et al. 2012; Nimmerichter et al. 2015). The significantly faster time to complete a 360 kJ time-trial at 60 compared with 90 rpm, does not affect parameters of oxygen uptake kinetics in a subsequent running task. Although the improvement in cycling time-trial performance does not impair the initial oxidative response during submaximal running, the effects on subsequent performance during a running time-trial, remains to be shown. **References** Nimmerichter A, Eston R, Bachl N, Williams C (2012) Effects of low and high cadence interval training on power output in flat and uphill cycling time-trials. OXYGEN UPTAKE KINETICS DURING FLAT AND UPHILL CYCLING AT HIGH-INTENSITY EXERCISE IN FIELD CONDITIONS

PRINZ, B., HASELSBERGER, K., NIMMERICHTER, A.

University of Applied Sciences, Wiener Neustadt

Introduction Oxygen uptake kinetics are the principal means by which the human organism generates energy to do work. Oxygen uptake kinetics are investigated by a number of studies in laboratory conditions. Few studies, however, have analysed oxygen uptake kinetics in field conditions. The aim of this study was to analyse the effect of gradient and cadence on the primary response of oxygen uptake kinetics in field conditions. **Methods** Thirteen trained cyclists (mean \pm SD: age 23 \pm 4.7 years; stature 178.5 \pm 5.2 cm; body mass 69 \pm 7.8 kg; VO_{2max} 68.2 \pm 4.7ml/min/kg) performed a laboratory incremental graded exercise test (GXT) and on a separate day four 6min field-trials, two on level ground (gradient 1.5%, flat) and two uphill (gradient 5%, climb). The two trials were conducted at a cadence of 60 and 90 rev/min (rpm) and at the work rate corresponding to 70% (Δ 70) between the power at ventilator threshold and Pmax of the GXT. Throughout each trial gas exchange was continuously measured with a portable gas analyser (MetaMax3B, CORTEX, Germany) and power output was measured with a SRM mobile power crank (Schoberer Rad-Messtechnik, Juelich, Germany). The V' O₂ breath-by-breath data were interpolated at 1-second intervals and the time constant and the amplitude of the exponential primary phase were resolved by least square regression (GraphPad Prism 6.0, GraphPad Software, USA). A factorial ANOVA with cadence and inclination as model factors was used for statistical analyses. **Results** The amplitude was significantly affected by cadence ($F_{1,12} = 39.3$, $P < 0.001$; 60 rpm: 2573 \pm 53 mL, 90 rpm: 2887 \pm 47 mL) but not by inclination ($F_{1,12} = 0.002$, $P = 0.967$; flat: 2731 \pm 172 mL, climb: 2728 \pm 272 mL). Time constant was not significantly affected by cadence ($F_{1,12} = 1.7$, $P = 0.213$; 60 rpm: 21.4 \pm 2.7 sec, 90 rpm: 23.2 \pm 2.2 sec) and inclination ($F_{1,12} = 3.9$, $P = 0.073$; flat: 24.0 \pm 1.1 sec, climb: 20.5 \pm 1.5 sec). The end-exercise oxygen uptake was significantly affected by cadence ($F_{1,12} = 55.3$, $P < 0.001$; 60 rpm: 4054 \pm 125 mL, 90 rpm: 4324 \pm 28 mL). No significant difference was observed between flat (4243 \pm 142 mL) and uphill cycling (4134 \pm 239 mL) ($F_{1,12} = 1.5$, $P = 0.245$). **Discussion** Our findings indicate that the parameters of oxygen uptake kinetics are not influenced by inclination. This is supported by previous studies who investigated the influence of inclination in treadmill running. Based on these findings we assume that measuring the primary response of oxygen uptake kinetics is independent of inclination. However, time constant is not influenced by cadence which is in contrast to the higher amplitude and end-exercise oxygen uptake at 90 rpm. ECCENTRIC VERSUS CONCENTRIC INCREMENTAL MAXIMAL CYCLING TEST

LIPSKI, M., ABBISS, C., NOSAKA, K.

Edith Cowan University

Introduction Eccentric cycling (EC) is less metabolically demanding than concentric cycling (CC) at the same power output (1). To determine eccentric cycling intensity, previous studies have used either a percentage of age-predicted maximum heart rate (2) or maximal power output obtained from a concentric incremental cycling test (1). Maximal power output during eccentric cycling was not assessed in the previous studies, and oxygen consumption (VO₂) and heart rate (HR) responses in incremental eccentric exercise have been not investigated. Thus, this study compared changes in VO₂ and HR in relation to power output between concentric and eccentric incremental maximal cycling test. **Methods** Eleven healthy participants (9 men, 2 women, 33.2 \pm 9.2 y) performed two incremental maximal cycling tests on separate days; first on a concentric cycling ergometer (Velotron, Washington USA) then on an eccentric cycling ergometer (Cyclus 2 Eccentric Trainer, Germany). Cycling intensity started at 75 W and increased by 25 W every minute until exhaustion. Participants were instructed to cycle above 60 rpm during CC, and to maintain the same cadence as CC during EC. When the target rpm could not be maintained for more than 30 s, the test was terminated. Gas exchange, heart rate and power output were measured continuously dur-

ing cycling, and compared between EC and CC by a t-test and Cohen's effect size (dz). Results Maximal power output was 53% greater ($P<0.001$; $dz=2.11$) for EC (438 ± 110 W) than CC (286 ± 55 W). Maximal HR during CC (182 ± 13 bpm) was not different ($P>0.05$; $dz=0.49$) from that of EC (176 ± 20 bpm). Peak VO₂ was 39% ($P<0.001$; $dz=1.14$) greater during CC (43.2 ± 6.8 ml/kg/min) than EC (31.0 ± 5.8 ml/kg/min). Discussion In spite of the 53% greater power output during EC than CC, peak VO₂ was 39% lower for EC than CC, yet maximal HR was similar between EC and CC. Thus, the relationship between VO₂ and HR in EC was different from that in CC. It has been shown that the magnitude of increase in adrenaline and noradrenaline is similar between EC and CC (3). It has also been reported that eccentric contractions increase muscle temperature more than concentric contractions (4). These differences may explain why HR responses were similar between EC and CC. In conclusion, the different relationship between maximal power output, VO₂, and HR should be considered when prescribing EC. An incremental protocol utilizing eccentric cycling may be more appropriate to determine exercise intensity in future investigations. References 1) Penailillo et al. OP-PM31 Strength Training - Assessment

1 RM DETERMINATION: A NOVEL APPROACH BASED ON THE FORCE-VELOCITY RELATIONSHIP

PICERNO, P.1, IANNETTA, D.2, PIACENTINI, M.F.2

1: "eCampus" University (Novedrate, Italy), 2: University of Rome "Foro Italico" (Rome, Italy)

INTRODUCTION Issues related to the direct determination of one repetition maximum (1RM) have led to the development of a variety of indirect approaches which make use of regression models to predict 1RM either from the capacity of lifting a submaximal load until failure or from strength-related variables collected during lifting increasing submaximal loads (Rontu et al., 2010; Jidovtseff et al., 2011). In both cases, accuracy of prediction is affected by all those factors that were involved in the construction of the model (i.e. exercise typology, age, gender, training level, number and cadence of performed repetitions) (Reynolds et al., 2006). Aim of the present paper is to assess the accuracy of 1RM as assessed by a novel, subject- and exercise-specific, methodology based on the force-velocity and the load-velocity relationships. **METHODS** The estimate of 1RM relied on the very definition of 1RM and consisted in identifying the intersection between the force-velocity and the load-velocity curves where the gravitational force exceeds the force that the subject can apply to the load. Force applied to the load and lifting velocity were collected in correspondence of at least three increasing loads by using an inertial sensor fixed on the load. The proposed force-velocity-based approach (FVM) was tested on 27 males (age: 23.9 ± 3.1) with no particular experience with resistance training in a leg-press (LP) and chest-press (CP) exercises. Agreement and association with respect to the direct measure of 1RM (DM), as determined in a separate session, were assessed using Bland-Altman's analysis and Pearson's correlation coefficient, respectively. **RESULTS** The means ($\pm SD$) of DM and FVM for CP were respectively 112 Kg (± 18.1) and 113 Kg (± 18.6). The means ($\pm SD$) of DM and FVM for LP were respectively 271 Kg (± 51) and 273 (± 51). The mean absolute percentage error was 1.2% for CP and 1.8% for LP. A high correlation between DM and FVM was found for both CP (0.998 ; $p < 0.001$) and LP (0.999 ; $p < 0.001$). A good level of agreement between DM and FVM was found for both CP (bias: -1.29 , 95% CI: 0.95 to -3.54) and LP (bias: -1.80 , 95% CI: 2.69 to -6.28). **DISCUSSION** Results suggest the proposed methodology as an accurate and safer alternative to the direct determination of 1RM. The mathematical construct is simply based on the definition of the 1RM and it is fed with subject's muscle strength capacities measured during a specific exercise. For this reason, its reliability is not prone to be affected by those factors that typically jeopardize regression-based approaches. **REFERENCES** Rontu JP, Hannula MI, Leskinen S, Linnamo V, Salmi JA. STRENGTH TRAINING: 10 RM VS 30 RM – TRAINING LOAD DOES MATTER

RØNNESTAD, B.R.1, ØFSTENG, S.1, KNOX, S.2, HAMMARSTRÖM, D.1, HELKALA, K.2, KNOX, B.2, JØSOK, Ø.2, HOLLAN, I.3, ELLEFSEN, S.1

Strength training: 10 RM vs 30 RM – training load does matter Introduction To maximize muscle hypertrophy and strength, heavy loads are often recommended (e.g. Ratamess et al., 2009). However, recent studies have challenged this view and claim that low loads can promote adaptations similar to high-load training, as long as it is performed to volitional fatigue (Burd et al. 2012; Mitchell et al., 2012). In the present study, we investigate the effect of high-load (H) vs. low-load (L) strength-training on maximal strength and lean body mass (LBM), as well as on performance in rapid movements such as counter-movement jump (CMJ) and during an agility test. Method Twenty-seven military students (20 ± 1 years, 75 ± 13 kg, $VO_{2\text{max}} 58 \pm 6$ mL·kg⁻¹·min⁻¹) with similar circadian rhythm, activity level, and nutrition intake were randomly assigned to high-load (H; 3x10RM, n=14) or low-load (L; 3x30RM; n=13) strength training regimes. Both groups trained the same seven exercises (3 lower body and 4 upper body) twice a week for 9 wks. The effects of the different strength protocols were measured in 1RM (leg press, bench press and biceps curl), agility, CMJ, and dual-energy X-ray absorptiometry assessments of LBM. Results There were no differences between the groups at baseline. H increased overall 1 RM (Σ leg-, bench-press and biceps curl) significantly more than L ($17 \pm 9\%$ vs. $10 \pm 6\%$, respectively, $p \leq 0.05$). H had also a larger performance improvement than L in both CMJ ($11 \pm 7\%$ vs. $5 \pm 7\%$, respectively, $p \leq 0.05$) and agility ($2.1 \pm 3.9\%$ vs. $-1.2 \pm 2.9\%$, respectively, $p \leq 0.05$). H had a tendency towards larger increase in LBM of the lower- and upper extremities than L ($5.0 \pm 3.7\%$ vs. $2.4 \pm 3.3\%$, respectively, $p = 0.056$). Effect size (ES) analyzes revealed moderate effects in favor of H vs L in 1RM, CMJ, agility and LBM (ES: 0.79, 0.78, 0.97, and 0.74, respectively). Discussion The main finding was that the H protocol improved 1RM, CMJ and agility more than the L protocol and tended to induce a superior increase in LBM, despite both protocols being performed to volitional fatigue, supported by moderate ES in favor of H vs L on all variables. This is in agreement with similar studies (e.g. Campos et al., 2002) and somewhat contrary to other studies (e.g. Mitchell et al. 2012). Indeed both protocols induced strength-training adaptations, but when the aim is to maximize performance in rapid movements such as CMJ and agility tests, H training seems

to be beneficial. References Burd et al. (2012) Appl Physiol Nutr Metab, 37, 551-554. Campos et al. (2002) EJAP, 88, 50-60. Mitchell et al. (2012) J Appl Physiol, 113, 71-77. Ratamess et al. (2009) Med Sci Sports Exerc, 41, 687-708. Contact bent.ronnestad@hi.no

EFFECTIVENESS OF AN OPTIMIZED TRAINING USING FORCE-VELOCITY PROFILE ANALYSIS

JIMÉNEZ-REYES, P.1, SAMOZINO, P.2, CUADRADO-PEÑAFIEL, V.3, BRUGHELLI, B.4, MORIN, J.B.5

1:Catholic University of San Antonio, Murcia, SPAIN; 2:LPE Lab, University of Savoie, FRANCE; 3:University Complutense Madrid, SPAIN;

4:SPRINZ, AUT, NEW ZEALAND; 5:LAMHESS, University of Nice, FRANCE

AIM: Ballistic performances, notably jumping, are key factors in many sport activities. They are mostly determined by the maximal power (P_{max}) that lower limbs can generate but also by the individual Force-velocity (F-v) mechanical profile characterizing the ratio between maximal force and maximal unloaded extension velocity capabilities. An individually optimal F-v profile has been shown to characterize the best balance between force and velocity capabilities (Samozino et al 2012, 2013). A F-v imbalance ($[F_v]_{IMB}$) being associated to lower performances. The F-v profile could be sensitive to specific and optimized training in order to improve ballistic performances. So training has to aim at increasing P_{max} and/or optimizing the F-v profile. Thus, the aim of this study was to determine the effects of an individual specific force-velocity profiling based-training. **METHODS:** Sixty-three subjects were assigned to three groups according to $[F_v]_{IMB}$ classification: a velocity and a force imbalance deficit groups and a control group (no consideration of $[F_v]_{IMB}$). Mean push-off force, velocity and power were calculated from jump height (Samozino's method, 2008). From this data, actual and optimal F-v profiles were computed for each subject to quantify $[F_v]_{IMB}$ and organize groups accordingly. Participants underwent a 9-week specific resistance training program designed according to $[F_v]_{IMB}$ classification to reduce imbalances for the intervention groups versus a one-size-fits-all program with no $[F_v]_{IMB}$ consideration for the control group. **RESULTS:** A greater increase in jump performance (16.6% and 13.3% in force and velocity groups, respectively) was observed in the intervention group, with a decrease in $[F_v]_{IMB}$ (-38.3% and -83.2% in force and velocity groups, respectively) compared to controls. **CONCLUSION:** An optimized and individualized training program specifically addressing the force/velocity imbalance is more efficient in improving jumping performance than a traditional resistance training common to all subjects, regardless of their force/velocity imbalance and optimal force-velocity profile. Thus, $[F_v]_{IMB}$ could be considered as a potentially useful variable for prescribing optimal resistance training to improve ballistic (e.g. jumping) performance. MUSCLE ACTIVATION AND MAXIMAL REPETITIONS NUMBER AS AN INDICATOR FOR STRENGTH IMBALANCE DURING CHEST PRESS EXERCISE

SEO, S.W., SONG, S.H., LEE, H.S.

Dankook University

Introduction Muscle imbalance or bilateral asymmetry can be interpreted as imbalance in strength between 2 halves of the body (Crosier, 2004), and many researchers have tested strength imbalance using isokinetic testing (Rahnama et al, 2005; Siqueira et al, 2002). However, as isokinetic equipment is too expensive, maximum repetition number could be used instead and research which examined imbalance of upper limbs using electromyography (EMG) is needed to be studied. This study tested the hypothesis that muscle activation would be higher in non-dominant compared with dominant pectoralis major during two-arm chest press exercise, but maximal repetition number would be higher in dominant compared with non-dominant pectoralis major during one-arm chest press exercise. Methods Ten healthy, resistance-trained males were tested for 1-RM the chest-press exercise, Two-arm at 80% of 1-RM and one-arm at 40% of 1-RM in the pectoralis major were measured for the maximal voluntary contraction (%MVC) by the EMG and maximal number of repetitions during the chest press exercise. Exercise velocity was constantly 4 seconds (concentric: 2-s, eccentric: 2-s) per repetition (Gentil et al., 2007). Results The changes in %MVC were significantly higher in the non-dominant compared with dominant pectoralis major during two-arm chest press exercise ($p < 0.05$). In contrast, the changes in maximal repetition number were significantly higher in the dominant compared with non-dominant pectoralis major during one-arm chest press exercise ($p < 0.05$). Discussion In Previous studies, 41 English Premier League club soccer players found bilateral strength differences in preferred and nonpreferred legs, using isokinetic testing (Rahnama et al, 2005). In this study, we demonstrated that changes in muscle activation are influenced by changes in maximal repetition number during one-arm chest press exercise. It is considered that maximal repetition number can be used as an indicator of strength imbalance. References Crosier JL. (2004). Int Sport Med J, 5, 169–176. Rahnama N, Lees A, Bambaecchi E. (2005). OPTIMAL LOADING CONDITIONS FOR MAXIMIZING POWER IN SLED RESISTED SPRINTING

CROSS, M.R.1, BRUGHELLI, M.1, SAMOZINO, P.2, MORIN, J.B.1,3

1Auckland University of Technology, 2University Savoie Mont Blanc, 3University of Nice Sophia Antipolis

INTRODUCTION Maximal power production (P_{max}) is considered central to sprinting performance (Rabita et al. 2015). Power profiling during sprinting has occurred through several different methods (e.g. Samozino et al. 2015), allowing the magnitude and balance of mechanical capacities to be quantified and compared. However, no attempt has been made to profile the optimal conditions for maximal power during overground sprinting. We assessed whether a multiple trial method, using a common sprint sled to supply resistance, could be used to profile mechanical relationships and optimal loading conditions during overground sprinting. **METHODS** 27 healthy mixed-gender athletes performed six to seven maximal velocity sprints towing a sled, loaded with a selection of masses (0-120% of body-mass), on an athletics track. For each trial, power was determined at maximum velocity (assessed via radar), from pre-determined friction force and aerodynamic drag. Individual composite linear force-velocity and parabolic power-velocity relationships, and associated mechanical variables and optimal loading conditions, were generated using variables from each trial. Least squares linear and quadratic regression fits, mean and the range of outcome mechanical variables were calculated. **RESULTS** Force-velocity and power velocity relationships were very well fitted with linear and 2nd order polynomial regressions, respectively ($R^2=0.977-0.999$; $P<0.001$). Mean P_{max} was 15.79 ± 2.47 W.kg $^{-1}$, with theoretical maximum force and velocity as 6.97 ± 0.70 N.kg $^{-1}$ and 9.13 ± 0.80 m.s $^{-1}$, respectively. The mean normal load (i.e. sled mass) that maximized power was $75\pm7\%$ of body-mass (range=65-90%), representing an optimal force of 3.5 ± 0.34 N.kg $^{-1}$ at a velocity of 4.58 ± 0.40 m.s $^{-1}$. **DISCUSSION** Power-force-velocity relationships can be accurately profiled using com-

mon sled training equipment and simple maximal speed data. Notably, the optimal conditions for maximizing peak power represented much greater resistance than that generally used in the literature (Petrakos et al. 2015), and appear to exist within wide ranges. This method has potential value in quantifying individualized training parameters for optimized development of horizontal power, which may reflect greater increases in applied performance measures than those currently used and recommended in practice. MUSCULAR ACTIVITY IN CONVENTIONAL AND DIFFERENTIAL BACK SQUAT EXERCISE

HORST, F., RUPPRECHT, C., SCHMITT, M., HEGEN, P., SCHÖLLHORN, W.I.

Johannes Gutenberg University Mainz

Introduction In conventional strength training, deviations from prescribed exercises are corrected and minimized. In comparison, the differential learning (DL) approach bases on movement variations and shows advantages for motor learning in sports and physical therapy (Schöllhorn et al., 2010). In comparison to conventional strength training, differential strength training is characterized by movement variations at lower external load. The application of the DL approach to strength training shows similar training effects as conventional training for the one repetition maximum (IRM) in back squats (Hegen et al., 2015). The aim of this study is to look for the effect of load and movement variations on the activity of selected leg muscles during the back squat exercise. **Methods** Seven healthy male subjects performed four sets of five back squats in each of three training conditions in a counterbalanced within-subject design. Differential back squat training based on movement variations at 60% 1RM (D60) and conventional back squat training on basis of movement repetitions at 60% 1RM (C60) and 85% 1RM (C85). Muscular activity of the dominant leg was measured using surface electromyography (Biovision, 4000 Hz) at gluteus maximus, vastus medialis, vastus lateralis, biceps femoris, gastrocnemius medialis, gastrocnemius lateralis and tibialis anterior. The raw signal was rectified, smoothed using a 150 ms window root mean square and normalized to the maximum. The mean activity and the coefficient of variation were determined. Differences between the training conditions were analyzed by means of repeated measures ANOVA. **Results** All muscles show significant differences with large effect sizes between the training conditions in mean activity ($p < .020$; $\eta^2 \geq .479$) and coefficient of variation ($p = .000$; $\eta^2 \geq .862$). Increased variation in muscular activity was obtained during back squats in D60 compared to C60 and C85. C85 is characterized by increased mean activity during back squats compared to C60 and D60. **Discussion** The results emphasize that the movement variations in back squat training lead to lower mean, but more variable activity of the leg muscles. The results indicate different underlying neuromuscular processes and adaptations in differential and conventional strength training. Therefore, performance improvement in the back squat through differential training (Hegen et al., 2015) can be explained by a combination of movement variations, intensity and time under tension. In contrast, effects of conventional strength training can only be explained by intensity. References Schöllhorn WI, Beckmann H, Davids K (2010). Medicina, 46(6), 365-73. INJURY PATTERNS AMONG ELITE FOOTBALL PLAYERS: A MEDIA-BASED ANALYSIS OVER SIX SEASONS WITH EMPHASIS ON PLAYING POSITION

LEVENTER, L., EEK, F., LAMES, M., HOFSTETTER, S.

Technische Universität München

The study objective was to describe types, localizations and severity of injuries among first division Bundesliga football players, and to study the effect of playing positions on injury incidence and severity based on information from public media. Information about exposure and injuries from 1673 players over 6.4 seasons were collected from a media-based register. The knee was the most frequent localization and had the longest recovery time ($p < 0.001$). Recovery following ligament injuries was significantly longer than muscle injuries. Significant differences between the playing positions were found in injury incidence and injury burden (lay-off time per incidence-rate), with wing-defenders sustaining significantly lower incidence-rates of groin injuries compared to forwards (rate ratio: 0.46, 95% CI: 0.21-0.99). Wing-midfielders had the highest incidence-rate and injury burden from match injuries while centre-defenders sustained the highest incidence-rate and injury burden from training injuries. There were also significant differences in match availability due to an injury across the playing positions, with midfielders sustaining the highest unavailability rates from a match and training injury. Injury-risk and patterns seem to vary substantially between different playing positions. Identifying positional differences in injury-risk may be of major importance to medical practitioners when considering preventive measures.

EXAMINING THE ASSOCIATION BETWEEN LOWER-LIMB MUSCLE COMPLAINTS AND MUSCLE FUNCTION IN SOCCER PLAYERS.

WAKEFIELD, K.J.1, WHALAN, M.D.1, LOVELL, R.2, SAMPSON, J.A.1

1: UOW /Australia, 2: WSU /Australia

Purpose: Lower-limb power, flexibility and hamstring strength are risk factors for time-loss injury; however, Fuller's 2006 consensus statement highlights injury as any physical complaint. This study therefore examined the hypothesis that muscle complaints will negatively correlate with lower limb flexibility, power and hamstring strength. **Methods:** 19 semi-professional soccer players (Male, 24 ± 3.1 yrs, 75.5 ± 9.5 Kg, 178.7 ± 6.0 cm) were recruited. Lower-limb power was assessed during 3 counter-movement jumps (Kistler portable force platform, CH-8408 Winterthur, Switzerland). Flexibility assessments of the hamstrings, quadriceps, calves and groin were performed using goniometry. Hamstring strength was assessed via maximum isometric (prone, 30° knee flexion) and isokinetic (prone, $0-135^\circ$ concentric/eccentric knee flexion $60^\circ/S$) dominant limb contractions. Muscle complaints were recorded weekly (frequency), allocated a

numerical value from 0-3 (based on reduction of participation) and summed to calculate a severity score (Clarsen et al., 2013). Pearson's correlations (r^2) were performed with significance set at $p \leq 0.05$. Results: 174 muscle complaints with a severity score of 190 were recorded. Hamstring complaints (47) were negatively associated with quadriceps flexibility ($r^2=0.34$; $p=0.0086$). Groin complaints (15; $r^2=0.43$; $p=0.0023$) and their severity (25; $r^2=0.32$; $p=0.0114$) were negatively correlated with adductor flexibility. No other relationships were observed. Discussion/conclusion: Flexibility measures were most associated to the frequency and severity of muscle complaints. The direct association between groin complaints and poor adductor flexibility is consistent with existing time-loss-groin injury reports (Ekstrand & Gillquist, 1982). Poor quadriceps flexibility has been shown to increase torque on the hamstring muscles during the late swing phase of sprinting, increasing hamstring injury risk (Gabbe et al., 2005). The effect of which could explain the indirect association we observed between hamstring complaints and poor quadriceps flexibility. In contrast to previous work, hamstring muscle strength assessments were not correlated with hamstring complaints. In summary, the results support a groin flexibility screening process to detect and prevent adductor injury. References: Clarsen B, Myklebust G, Bahr R (2013). SKELETAL MATURATION ASSOCIATED WITH LOWER LIMB MUSCLES FLEXIBILITY IN HIGHLY TRAINED YOUNG SOCCER PLAYERS

MATERNE, O.1, FAROOQ, A.2, CHAMARI, K.2, JOHNSON, A.1, GREIG, M.3, MCNAUGHTON, L.3

1: Aspire Academy, NSMP (Doha, Qatar), 2: Aspetar, Qatar Orthopaedic and Sports medicine Hospital (Doha, Qatar), 3: Edge Hill University (Lancashire, England)

Introduction Flexibility has been shown to be a key factor for performing football-specific tasks (Garcia-Pinillos et al., 2015) in youth soccer. Yet, the understanding of changes in lower limb muscle flexibility during maturation, remain limited. This study examined the relationship between skeletal age and the flexibility of the lower limb muscle groups in young elite Qatari soccer players. It was hypothesized that skeletal maturity status influences the flexibility of the lower limb muscles. Methods 188 youth soccer players (Mean: age: 14.4 ± 1.5 years; weight: 50.7 ± 10.9 kg; height: 162.5 ± 10.7 cm) were measured in pre-season screening over six consecutive years in six different age groups (U13 to U18). Flexibility of eight muscle groups (quadriceps, hamstrings, adductors, hip flexors, gastrocnemius, soleus, hip medial-, and hip lateral- rotators) were bilaterally and consistently measured using a reliable method (Fourchet et al., 2012). Skeletal age (SA) was estimated by an experienced observer using the Fels method. Linear mixed model analysis was used to compare the flexibility with maturity status (SA minus chronological age: Late (L): > -1 year; Normal (N): $+/-1$ year; Early (E): < 1 year) within each age group. Results Data from 852 limbs for each muscle group were available for analysis. Flexibility of all lower limb muscle groups decreased significantly with age. Substantial variations within identical age categories but different maturity status were reported, e.g. Quadriceps (U16: E: $128.2 \pm 0.9^\circ$ > N: $132.7 \pm 1.3^\circ$ > L: $141.7 \pm 4.5^\circ$, $p < 0.05$); Gastrocnemius (U16: E: $11.4 \pm 0.7^\circ$ > N: $14.7 \pm 0.9^\circ$, $p < 0.05$); Soleus (U16: E: $28.5 \pm 0.8^\circ$ > N: $33.7 \pm 1.1^\circ$ > L: $39.5 \pm 3.9^\circ$, $p < 0.05$); Medial rotator (U16: E: $49.2 \pm 1.6^\circ$ > N: $54.9 \pm 1.6^\circ$, $p < 0.05$); Hamstring (U14: E: $65.9 \pm 1.3^\circ$ > L: $83.7 \pm 5.1^\circ$, $p < 0.05$); Adductor (U15: E: $57.1 \pm 0.9^\circ$ > N: $60.1 \pm 0.8^\circ$ > L: $71.1 \pm 3.6^\circ$, $p < 0.05$); Lateral rotator (U15: E: $36.4 \pm 1.2^\circ$ > N: $37.7 \pm 1.2^\circ$ > L: $49.7 \pm 4.9^\circ$, $p < 0.05$). Hip flexors did not show any substantial difference between the maturity status in any age group. Conclusion This study revealed that lower limb muscle flexibility changes through skeletal maturation and appeared to be muscle group dependent. Such information will enhance the understanding of lower limb flexibility changes during maturation, and will help youth soccer academies to initiate appropriate developmental strategies. EVALUATION OF DEXTROSE PROLOTHERAPY INJECTIONS IN SOCCER PLAYERS WITH CHRONIC GROIN PAIN

EROGLU, A., SARI, A.

Erenkoy physical medicine and rehabilitation hospital

Evaluation of Dextrose Prolotherapy Injections in Soccer Players with Chronic Groin Pain INTRODUCTION Groin pain is a very common problem in soccer. Among male soccer players, the incidence of groin pain is estimated at 10% to 18% per year (Holmich P et al.). The most common causes of chronic groin pain in soccer players are adductor strain and osteitis pubis. One important disease to consider in the differential diagnosis of groin pain in athletes is osteitis pubis: a painful, inflammatory process involving the pubic symphysis and its surrounding structures such as the pubic rami, cartilage, musculotendinous and ligamentous structures of the pelvis (Batt ME et al 1995; William PR et al 2000). Our study is that chronic, overuse-related, and performance-limiting osteitis pubis in soccer players can be treated effectively using dextrose prolotherapy, despite failure of nonsurgical treatment for a minimum of 6 months. METHODS Most patients were referred by the orthopedic surgeon and team physician of the regional soccer team Turkey. Twenty patients were soccer players and 3 were regional endurance athletes. Dextrose prolotherapy injection sessions occurred between three weeks (0-3-6 weeks). The solution used was a combination of 20% dextrose and 1% lidocaine simplex. It was prepared by mixing 10mL of 1% preservative- and epinephrine-free lidocaine simplex with 10mL of 20% dextrose solution in a 20mL syringe at pubic rim on either side of the symphysis pubis in 1-cm intervals, covering the pecten origin and pyramidalis insertion, external oblique insertions, and the superior pelvic rim. RESULTS A pretreatment visual analog scale (VAS) for pain with exercise was administered, and each subject was asked to fill out the Nirschl Pain Phase Scale (NPPS) to determine his functional impairment level. Variables Pretreatment • Posttreatment • Mean Difference Before to After Treatment SEM Difference P†† VAS rating for sports pain 6.7 ± 1.4 1.2 ± 2.0 -5.5 $0.5 < .001$ NPPS score 5.0 ± 0.7 0.9 ± 1.7 -4.1 $0.5 < .001$ DISCUSSION Dextrose injection prolotherapy at 3-week intervals was highly clinically effective in the treatment of chronic groin pain in these soccer players. This pilot study suggests a new clinical frontier for physiatrists and other musculoskeletal physicians; however, larger controlled trials are needed to confirm our findings. A GENETIC-BASED ALGORITHM FOR PERSONALIZED RESISTANCE TRAINING IN SOCCER PLAYERS

SURACI, B., JONES, N., KIELY, J., PICKERING, C., COLLINS, D., DE LORENZO, D., GRIMALDI, K.

University of Portsmouth

Introduction Resistance training leads to increases in maximal running speed, acceleration, jumping abilities, force in kicking, tackles and headers and reduces the risk of injuries in soccer players. Association studies have identified dozens of genetic variants linked to training responses and sport-related traits. However, no intervention studies utilizing the idea of personalized training based on athlete's genetic profile have been carried out, especially in soccer. Here we propose an algorithm that allows achieving greater results in response to high- or low-intensity resistance training program by predicting an athlete potential for the development of power and endurance qualities with a panel of 15 performance-associated gene polymorphisms. These polymorphisms are located within the genes primarily involved in the regulation of muscle fibre type composition and muscle size, cytoskeletal function, muscle damage protection, metabolism, circulatory homeostasis, mitochondrial biogenesis, thermogenesis and angiogenesis. Methods Soccer players (n=39) completed an eight-week high- or low-intensity resistance training program, either matched or mismatched to their individual genotype. The high-intensity resistance training program consisted of ten sets of two reps over the eight-week study. The low-intensity resistance training program consisted of three sets of ten reps for first two weeks, three sets of fifteen reps for the next three weeks and three sets of twenty for the last three weeks. Two variables of explosive power and aerobic fitness, measured by the countermovement jump (CMJ) and aerobic 3-min cycle test (Aero3), were assessed pre and post 8 weeks of resistance training. DNA samples of athletes were genotyped for the ACE I/D, ACTN3 R577X, ADRB2 Gly16Arg and Gln27Glu, AGT M235T, BDKRB2 rs1799722 C/T, COL5A1 rs12722 C/T, CRP rs1205 A/G, GABPB1rs718166 A/G, IL6 -174 C/G, PPARA rs4253778 G/C, PPARGC1A G482S, TRHR rs16892496 A/C, VDR rs1544410 A/G, VEGFA rs2010963 G/C gene polymorphisms by real-time PCR. The percentage power/endurance genotype score (P/E) ratio was determined for each athlete. Results Following the training intervention, players from the matched group (i.e. high-intensity trained with power genotype or low-intensity trained with endurance genotype) have demonstrated significantly greater ($P < 0.0001$) performance changes in both tests compared to mismatched group (i.e. high-intensity trained with endurance genotype or low-intensity trained with power genotype). CMJ improved by 7.1% in the matched group, compared to 2.4% in the mismatched group. Improvements in Aero3 were 7.7% in the matched vs 1.9% in the mismatched group. Conclusion Our results indicate that matching the individual's genotype with the appropriate training modality leads to more effective resistance training. The developed algorithm may be used to guide individualized resistance-training interventions.

SUGAR AND MICRONUTRIENT INTAKE WITHIN ELITE YOUTH BRITISH SOCCER PLAYERS: THE NUTRITIONAL TRANSITION FROM SCHOOLBOY TO FULLTIME SOCCER PLAYER

NAUGHTON, R.1, DRUST, B.2,3, O'BOYLE, A.2,3, MORGANS, R.3, ABAYOMI, J.1, DAVIES, I.G.1, MORTON, J.P.2, MAHON, E.2

Liverpool John Moores University

Introduction It is recommended that soccer players consume a diet high in carbohydrate to augment performance. However, growing evidence suggests there is a link between high free-sugar intake (>5% total energy intake (TEI)) and some metabolic diseases (1). Additionally, recent data has found that soccer players are at risk of oral caries, which was linked to free-sugar intake (2). Little is currently known about the free-sugar intake within elite British youth soccer players and, consequently, their risk to adverse health conditions. We therefore tested the hypothesis that elite British youth soccer players consumed above the current UK DRV (5% TEI) for free-sugars. Method Players from an English Premier League academy under (U) 18 (n = 13); U15/16 (n = 25); U13/14 (n = 21) completed a 7-day food diary over a training period in which no competitive games took place. Upon analysis, using dietary analysis software (Nutritics Ltd, Ireland), these data were compared to the current UK DRV for free-sugar via a t-test. Intakes between squads was analysed using a one-way ANOVA. All data are expressed as means (SD), statistical significance $p < 0.05$. Results The U13/14s (TEI, 10.0 17.7%) and U15/16s (TEI, 11.2 30.0%) both consumed higher amounts of free-sugar in comparison to the UK DRV of TEI 5% ($P < 0.01$), conversely, the U18s (TEI, 5.1 12.7%) were no different from the DRV. Furthermore, the free-sugar intake of the U18s was significantly lower than that of the U13/14s and U15/16s ($P < 0.01$). Discussion Our data provides novel evidence on the free-sugar intake across a range of ages within an elite youth British soccer academy. It would appear that there is a shift in nutritional habits from when a player transitions to fulltime (U18s) from schoolboy (U13-U16s). However, it may be put forward that as the tested population are athletes they may have need for a higher carbohydrate intake in comparison to the UK DRV, which may lead to higher free-sugar intake than the general population. Further research is needed to establish if there is any health risk to this population as a result of an increased free-sugar intake (>5% TEI). References 1Stanhope. (2015). Crit. Rev. Clin. Lab. Sci. 1-16. 2Freeman. (2014). Evid. Based. Dent. 15(4):98-99.

TRACKING OF TELEVISION VIEWING FROM YOUNG ADULTHOOD TO MIDLIFE OVER 25 YEARS

YANG, X.1, KANKAANPÄÄ, A.1, BIDDLE, S.J.H.2, HIRVENSALO, M.3, RAITAKARI, O.T.4, TAMMELIN, T.1

1: LIKES (Jyväskylä, Finland), 2: ISEAL (Melbourne, Australia), 3: UJ (Jyväskylä, Finland), 4: UT (Turku, Finland)

Introduction Despite the increase in television (TV) viewing tracking research on young people, no study has shown whether the specific sedentary behavior persists from young adulthood to middle age. The aim of the study was to examine the tracking of TV viewing from young to middle adulthood over 25 years. Methods A random sample of 3082 participants aged 9-24 years participated in the Young Finns Study in 1986. The follow-up measurements were repeated in 2001, 2007 and 2011. TV viewing during leisure time was measured with a single self-report question for 18-49 year olds. Tracking of TV viewing was analyzed using Spearman's rank order correlation and a simplex-model. Baseline status (level) and overall growth (slope) for TV viewing was also analyzed via latent growth model in the multi-level context. Results TV viewing at age 18 to 24 in 1986 significantly predicted TV viewing in young and midlife adulthood. There was a significant indirect effect of TV viewing in the younger cohorts from young to midlife adulthood in both genders. Simplex models that fitted the data very well produced higher stability coefficients than the Spearman rank order correlations showing moderate or high tracking. The levels of TV viewing appeared to be significantly affected by gender and age over time. Discussion This study has shown that the

daily amount of TV viewing is stable during adulthood and that the stability of TV viewing is predominantly moderate or high throughout adulthood. However, the stability varies in magnitude between men and women in different age groups. Future studies may need to investigate how this changes, if at all, with the changing nature of TV provision and access, and associated ubiquitous provision of screen-based media. DETERMINANTS IN EARLY ADULTHOOD OF LEISURE-TIME PHYSICAL INACTIVITY STABILITY AND CHANGE IN MID-LIFE

PINTO PEREIRA, S., POWER, C.

University College London

Background: Physical inactivity has a high prevalence and associated disease burden. Knowledge is needed of influences that change or sustain inactive lifestyles. We aimed to establish whether factors in early adulthood predict subsequent inactivity patterns after accounting for influences from earlier life. **Methods:** Leisure time inactivity (frequency<1/wk) was assessed at 33y and 50y in the 1958 British Birth cohort (N=12,271). Early adult factors (23-33y) were grouped in physical and social domains. We assessed associations of factors within domains separately and combined with four 33-50y inactivity patterns (never inactive, persistently inactive, deteriorating or improving) using multinomial logistic regression and adjusting for factors from early life. **Results:** Approximately 31% of the population were inactive at 33y and 50y; 35% changed their inactivity status 33-to-50y with 17% deteriorating and 18% improving. In analyses of physical and social domains combined, factors associated with inactivity persistence vs never inactive were physical limiting illness (21% higher risk/duration exposed), obesity (30% higher/duration exposed), perceived underweight (31% higher vs 'right weight'), height (7% lower/5cm), depression (32% higher/duration exposed); education (30% higher/reduction on 5-point scale) and neighbourhood, i.e. suburbs and service centres, rural areas and seaside resorts or growth areas (32%, 38% and 16% lower vs stable industrial areas respectively). Associations were broadly similar for inactivity deterioration. Factors associated with improvement were suburb and service centre neighbourhood (36% higher vs stable industrial areas) and number of children, although the association varied by age with a lower risk at 23y and higher risk at 33y of approximately 13%/child. Associations remained, albeit attenuated, after adjustment for early life factors. **Conclusions:** Both physical and social factors in early adulthood predicted inactivity persistence and deterioration, while only social factors predicted improvement. In particular, the neighbourhood in which individuals lived in young adulthood had long-lasting associations with inactivity patterns.

EATING BEHAVIOUR AND NUTRITIONAL KNOWLEDGE IN ELITE ADOLESCENTS PRACTISING SYNCHRONISED SWIMMING. A NUTRITIONAL INTERVENTION

GHIANI, G., MAGNANI, S., DI GIACOMO, A., VANNI, S., SAINAS, G., PALAZZOLO, G., RUIU, P., CRISAFULLI, A., TOCCO, F.

University of Cagliari

Introduction Synchronized swimming combines speed, power and endurance with precise synchronized movements and high-risk acrobatic manoeuvres. Because of the aesthetic nature of the sport, which prioritizes leanness, the risks of energy and macronutrient deficiencies are a significant concern. Relative Energy Deficiency in Sport (RDA-s) and disordered eating/eating disorders are also of concern for these female athletes (Robertson et al., 2014). The aim of this study was to check whether a group of elite adolescent practising synchronised swimming had a proper diet matching the Italian nutritional advices, and to program a nutritional intervention for the athletes and their families and coaches. **Methods** 13 elite adolescents synchronized swimmers (age 15±1.0 years, BMI 21±2.4, fat mass 26.7 ±8.4%) participated in the study. They attended an interview about their life style and their training and a validated dietary questionnaire on food habits, eating behaviour and nutritional knowledge of adolescents (Turconi et al., 2003). Then data were compared with the nutritional advices from the Italian Government and some nutritional interventions were made to help the athletes to reach a better nutritional status. For each subject fat mass was detected by means of plicometry method (Slaughter et al., 1988). **Results** The processing of the questionnaire evidenced a lack in the consumption of carbohydrates, fruits and vegetables. Moreover, 17% of the athletes had the habit of totally skipping breakfast and all of them reported inadequate daily distribution of meals. Finally, questionnaire highlighted serious problems with the lunch management because their daily training in the swimming pool was too close to lunchtime. **Discussion** Disordered eating behaviour and eating disorders are of great concern because of their associations with physical and mental health risks and, in the case of athletes, impaired performance. To prevent RDA-s, aquatic athletes have to practice healthy eating behaviour, and coaches and athletes' health care teams must be conscious that early interventions are needed to prevent this kind of problems especially in adolescents athletes (Melin et al., 2014). OBJECTIVELY-MEASURED SLEEP PATTERNS DURING SCHOOL AND NON-SCHOOL DAYS IN ICELANDIC ADOLESCENTS

ROGNVALSDOTTIR, V.1, GUDMUNDSDOTTIR, S.L.1, BRYCHTA, R.J.2, HRAFNKELSDOTTIR, S.M.1, ARNGRIMSSON, S.A.1, CHEN, K.Y.2, JOHANSSON, E.1

University of Iceland

Introduction Sleep plays an important role in adolescents' health. Short sleep and poor sleep quality are associated with obesity, low physical fitness and academic performances in adolescents. Actigraphy has been used as an objective method for assessing patterns and estimating general qualities of sleep in free-living conditions. In this study, sleep and activity was continuously monitored for one week using actigraphy in a group of primary-school adolescents. **Methods** A cross-sectional cohort of 301 tenth-grade students from six elementary schools in Reykjavík, Iceland was studied in the spring of 2015. Free-living sleep and physical activity were measured with wrist-worn raw signal accelerometers (ActiSleep by Actigraph). Total sleep time (TST), sleep efficiency (SLE), number of awakes (NOA), sleep fragmentation index (SFI), wakening after sleep onset (WASO), bed time (BT), midpoint of sleep (MS) and rise time (RT) were computed for school days (SchD) and non-school days (NSchD). Averages of daily sleep parameters (≥ 3 SchD and ≥ 1 NSchD was considered valid) were compared using paired and group t-tests as appropriate. **Results** 93.4% of the students (114 boys and 167 girls) had valid sleep data. Only 23.4% of the girls and 20.2% of the boys met the sleep recommendation of 8 hours per night (time in bed) on average for the week, and even less on SchD. On SchD, mean TST per night was 6.2 ± 0.7 hours, with SLE of $87.9 \pm 4.4\%$, and no differences between the sexes. On NSchD, TST significantly increased to 7.3 ± 1.1 hours ($p < 0.001$) for the whole group resulting from significant delays in BT and RT on NSchD compared to SchD (1.3 and 2.7 hours respectively, $p < 0.001$). Boys had later BT than girls on NSchD (about 27 min,

p=0.003) but not on SchD and their RT was also later than girls on NSchD (35 min, p<0.001) and on SchD (10 min, p<0.001). Despite of longer TST on NSchD, actigraphy markers (SLE, WASO, NOA and SFI) indicated significantly lower sleep quality on NSchD than SchD (p's<0.005). Discussion Our data indicates that the majority of Icelandic adolescents do not get the recommended amount of sleep on school days and may need to "recover" by sleeping longer on the non-school days. The pattern of going to bed late (especially for boys) is the major contributor. The effect of insufficient sleep on adolescents' health and well-being may be serious. However, sleep in adolescent is modifiable, which hopefully raise the attention for parents, educators, society, and policy makers. HIGH LEVELS OF PHYSICAL ACTIVITY DOES NOT IMPAIR SLEEP QUALITY IN ADOLESCENTS: DADOS STUDY

BELTRAN-VALLS, M.R., ARTERO, E.G., CAPDEVILA-SEDER, A., LEGAZ-ARRESE, A., ADELANTADO-RENAU, M., MOLINER-URDIALES, D.

Universidad Jaume I - LIFE Research Group

INTRODUCTION: Adequate sleep is an essential health aspect during youth for optimal physical, psychosocial and cognitive development (Shochat T et al., 2014). Physical activity (PA) has been highlighted as a useful tool to improve sleep disturbances in adolescents, but results are not conclusive (Lang C et al., 2016). The aim of our study was to analyze the association between objectively measured PA and sleep quality in adolescents. METHODS: A total of 205 adolescents aged 13y.o. from the DADOS study (86 girls, 119 boys) were included in the analysis. PA was assessed by a wrist-worn GENEActive accelerometer (Activiinsights Ltd, Kimbolton, UK) and expressed as min/day of sedentary, light, moderate, vigorous and moderate and vigorous PA (MVPA) (Schaefer CA et al., 2014). PA values were dichotomized into <60 min/day and >=60 of MVPA. Sleep quality was evaluated with the Spanish version of Pittsburgh Sleep Quality Index (PSQI) (Royuela & Macías 1997). PSQI values were dichotomized into >5 (poor quality) or <=5 (good quality). RESULTS: None of the PA variables were associated with sleep quality. Achieving PA recommendations of at least 60 min/day of MVPA was not associated with presenting poor (PSQI >5) or good (PSQI <=5) sleep quality. DISCUSSION: Our results support those reported by Lang C et al. (2013) showing that, in adolescents, objectively measured PA is not associated with sleep quality. CONCLUSION: High levels of PA do not impair sleep quality in adolescents. Further studies are required to clarify the relationship between PA and sleep patterns in adolescents. EPIDEMIOLOGY OF INJURIES IN CHILDREN PARTICIPATING IN NATIONAL LEVEL KARATE COMPETITION

CIERNA, D., ARGAJOVA, J., LYSTAD, R.P.

Comenius University

Introduction Although several prospective studies have investigated the injury problem in elite karate competition for seniors to date, there is very limited data regarding younger karate athletes (e.g. cadets and juniors). Children and adolescents are increasingly taking part in organized training and competition in combat sports, which are promoted as safe and healthy activities. The purposes of this study, therefore, were to determine the injury incidence, describe the injury pattern, and identify potential risk factors for injury in modern children competitive in national level karate competition. Methods Prospective injury surveillance were undertaken at two consecutive national karate competitions in Slovakia (Slovak Cup, April 2015 and Slovak Championships, May 2015). Data were collected in situ using checklists following the same protocols used in previous investigations at the World Karate Championships (Arriaza et al., 2016). Collected injury data included body region, type of injury, mechanism of injury, severity, and treatment. Injuries were classified according to the Orchard Sports Injury Classification System version 10. The injury incidence rate (IIR) was calculated both per 1000 exposures and per 1000 exposure-minutes using standard methods. Rate ratios (RR) were calculated with 95% confidence intervals (95% CI) to identify potential risk factors. Results The sample consisted of 472 karate athletes (344 boys and 128 girls) with an age range of 6–11 years. The athletes competed in a total of 216 bouts, and sustained a total of 33 injuries, none of which resulted in time-loss from play. The overall IIR was 95.93 (95% CI: 66.03–134.72) per 1000 exposures and 77.37 (95% CI: 53.26–108.66) per 1000 exposure-minutes. The most commonly injured anatomical regions were the head (60%) and trunk (20%), while the most common types of injury were contusion (88%) and epistaxis (6%). Discussion The present study reveals that the IIR for young karate athletes competing at national level in Slovakia is similar to that of young athletes competing in the Open Dutch Karate Championship (Pieter, 2010) but greater than that of elite athletes competing at the World Karate Championships (Arriaza et al., 2016). Further efforts are required to prevent and control injuries in karate. References Arriaza R, Inman D, Arriaza A, Saavedra MA. OP-PM74 Mental Disabilities: Paralympics

LEVELS OF ADIPOSITY AND OTHER ANTHROPOMETRIC PARAMETERS IN SOCCER PLAYERS WITH INTELLECTUAL DISABILITY PARTICIPANTS IN ADAPTED SPORT COMPETITIONS.

LIZONDO, V.I, ESCRIVÁ, D.2,3, PÉREZ-ENCINAS, C.4, BARRIOS, C.2

Universidad Católica de Valencia San Vicente Martir

Introduction Obesity and/or overweight in adolescents and adults with intellectual disabilities (such as Down syndrome) are well described in the literature (González-Agüero et al., 2011). There are few data on body composition in athletes with intellectual disabilities participating in competitive sports (Pitetti et al., 2013). The aim of this work was to determine the anthropometric characteristics and body composition of a group of soccer players with intellectual disabilities, with special reference to the levels of adiposity. Methods The study sample consisted of 38 adolescents and young adults with mental disabilities enrolled in competitive sport (soccer): 24 suffered consequences of infantile cerebral palsy (CP) and 14 had Down syndrome (DS). The average age was 25.4±8.6. Anthropometric measurements

including skinfold thickness (biceps, triceps, subscapular, abdominal, suprailiac, thigh and leg) were performed following the ISAK recommendations. The percentage of body fat (%BF) was calculated from measurements of skinfold equations as proposed by Faulkner, Reilly et al., and Yuhasz. The somatotype was assessed by the technique of Carter and Heath. Differences were established by groups of etiology of disability. Results As compared to subjects with CP, individuals with DS were smaller (158.3 ± 7.7 vs. 168.5 ± 9.4 cm, $p < 0.01$), and had an increased %BF (Yuhasz: 18.7 ± 7.8 vs. 13.5 ± 5.0 , $p < 0.01$) (Faulkner: $20.9 \pm 7.8\%$ vs. $16.8 \pm 6.2\%$, $p < 0.01$). The skinfolds of the leg, thigh and abdomen were also significantly thicker in patients with DS than patients with CP. Muscle weight was higher in subjects with CP (55.2 ± 10.2 kg) than with DS (48.8 ± 13.9 kg), but without statistically significant differences. Regarding somatotype, there were only significant differences between the two groups in the endomorphic component, being higher in subjects with DS (6.24 ± 2.46 versus 4.54 ± 2.16 , $p < 0.05$). Discussion This research shows for the first time evidence that adolescents and young adults with Down syndrome involved in competitive sport have higher levels of total and regional fat (trunk and lower extremities) than the disabled athletes with cerebral palsy. This high adiposity together with the lower levels of cardiovascular and strength capacities describes in this population (Guerra et al., 2003), can result in a high risk of adverse events when performing competitive sports. Particular attention could be considered in future research to the limits and implications for their health and possible intervention through sport. THE EFFECT OF HYDROTHERAPY IN THE TREATMENT OF BEHAVIORAL ASPECT OF CHILDREN WITH AUTISM SPECTRUM DISORDERS

HOU, X., FENG, Y., MA, Z., WU, Y., TIAN, X., MU, W.

Guangzhou Sport University

Introduction Hydrotherapy is used as a treatment for children with disabilities and motor delays. The purpose of this study was to determine the effectiveness of a 4 week swimming program guided by Halliwick method on children with ASDs on behavior and aquatic skills. Methods 32 children with ASDs were included in this study, which are diagnosed by the Diagnostic and Statistical Manual of Mental Disorders (4th Edition, DSM-IV) of United States. They are mild-to-moderate degree classified by Children Autism Rating Scale (CARS). They were divided into experimental group and control group at randomly. Experimental group did four weeks swimming learning program guided by Halliwick conception, 5 days every week, 1.5 hours every day. The control group just did in routine life; Before and after the experiment, do the behavior evaluation by the Autism Behavior Checklist (ABC) and aquatic skills evaluation by the Humphries Assessment of Aquatic Readiness (HAAR). Results 1. There were significant differences of HAAR between the two groups after experiment in stage III(water entry), stage III(rotation) and stage VI(water independence movement) ($p < 0.05$). And no differences in other phases ($p > 0.05$). 2. There were significant differences of ABC scores between the two groups after experiment in B (body), and S2 (self-care) area ($p < 0.05$), there were no significance in S (feeling), R (skills) and L (language) areas ($p > 0.05$). 3. After experiment, In the experimental group, there were significant differences of ABC scores in B (body) and S2 (self-care) ($p < 0.05$) and no significant difference in S (feeling), R (skills) and L (language) ($p > 0.05$). There was no significant difference of ABC scores in the control group. Discussion Children with ASDs present with impairments in social interactions; communication; restricted, repetitive, and stereotyped patterns of behavior, interests, or activities; as well as motor delays. Hydrotherapy is used as a treatment for children with disabilities and motor delays. In this study, the results shown that adapted aquatic guided by Halliwick method can improve autistic children's body movement and self-care ability. Halliwick methods are based on sound hydrodynamic principles. It is aim to help individuals with disabilities become independent swimmers. Based on the adaptation of scientific and hydrodynamic principles to the behavior of the human body in water, The Halliwick Method emphasizes the goal of individual independence. No buoyant aids are used during Halliwick activities. An individual learns natural, self-initiated motor control. Group activities, logical extensions of one on one progression, are emphasized, with groups made up of student/instructor pairs. All components are based on McMillan's original ten-point program. In conclusion, the Halliwick method is an ideal therapeutic intervention of behavioral aspect for individuals with ASDs.

GAIT IN ADULTS WITH INTELLECTUAL DISABILITIES AND ITS ASSOCIATION WITH PHYSICAL FITNESS

OPPEWAL, A., HILGENKAMP, T.I.M.

Erasmus MC

Aims: Gait is a highly relevant and complex aspect of motor functioning. Poorer gait is a predictor for future disability, cognitive impairments, institutionalization and mortality. Since gait can be considered a complex cognitive task, and motor and cognitive functioning are fundamentally interrelated, it is not surprising that gait disturbances and delayed motor development are often seen in people with intellectual disabilities (ID). In the general population, physical fitness is an important aspect for gait. However, it is not known if physical fitness is related to gait in people with ID, because the impaired motor development in itself may alter that relationship. In this study, gait characteristics of people with ID were investigated, along with the association between gait and physical fitness. Methods: A cross-sectional study was performed to assess spatial and temporal gait characteristics of 31 adults (42.77 ± 16.70 years) with mild to moderate ID without Down syndrome. Gait was assessed with the GAITRite, at comfortable and fast walking speed. With regard to physical fitness we measured body composition (height, weight, BMI, waist circumference), muscular endurance (chair stand test), grip strength (hand dynamometer), and balance (four stances). Differences between gait characteristics at comfortable and fast walking speed were analyzed, along with associations between gait characteristics and physical fitness results. Results: An overview of the gait characteristics of adults with ID at comfortable and fast walking speed is provided. Most gait characteristics were significantly different between walking at comfortable and fast speed, except for base of support, toe in/ toe out and the within-subjects standard deviations of the gait variables. The physical fitness tests were associated with some of the gait variables. Conclusion: This study provides an overview of the gait characteristics of adults with ID, which were comparable to those found in a large study in community-dwelling adults of the general population ($n = 1500$) who were on average 20 years older, thereby representing an older gait pattern. The differences between walking at comfortable and fast speed do imply a physical reserve of adults with ID to alter their gait. The associations between physical fitness and gait provide directions for further research regarding possible interventions to improve gait of adults with ID. To understand the relationship between the gait characteristics of adults with ID and health outcomes, future studies should focus on the relationship between gait characteristics and negative health outcomes in this specific population, such as higher energy expenditure, falls, and future disability.

CARDIOVASCULAR RISK FACTORS AMONG ATHLETES WITH INTELLECTUAL DISABILITY PARTICIPATING IN THE BAVARIAN SPECIAL OLYMPICS GAMES

PETERS, C.1, SCHLAMMERL, K.2, KÖCK, C.2, ENGL, T.1, OBERHOFFER, R.1

1: Institute of Preventive Pediatrics, Technische Universität München

Introduction Obesity in early life seems to be a predictor of various secondary health conditions (Kelsey et al. 2014). For this reason the high prevalence of cardiovascular risk factors especially in young people with intellectual disability (ID) demands alertness (Wallén et al. 2009). The aim of this cross sectional study was to determine the prevalence of cardiovascular risk factors in people with ID participating in the Health Promotion Program during the Bavarian Special Olympics Summer Games 2013. Methods Out of 213 athletes (9-66 years) anthropometric data, blood pressure (SBP, DBP), % body fat and number of foot-tappings were gathered. Statements concerning health conscious behavior (smoking, physical activity, media consumption) were collected using interviews. Overweight and obesity, arterial hypertension, BMI, waist to hip (WHR) and waist to height (WHtR) ratios were defined using standard international criteria. Results More than every second athlete (56.3%) was either overweight or obese (average BMI: adults 27.98 ± 7.03 , adolescents 23.28 ± 5.22) with a significantly higher prevalence in adult than in young athletes ($\chi^2(3)=9.193$; $p=0.027$). Average WHtR exceeded critical values for adults ($\sigma 0.542 \pm 0.083$, $\varphi 0.574 \pm 0.110$) as well as for adolescents ($\sigma 0.487 \pm 0.063$, $\varphi 0.487 \pm 0.071$) indicating an increased health risk. One out of five athletes (22.2%) showed arterial hypertension. Significant correlations could be found between blood pressure and WHR (SBP: $r(196)=0.271$, $p<0.001$; DBP: $r(196)=0.238$, $p=0.001$) as well as WHtR (SBP: $ps(197)=0.218$, $p=0.001$; DBP: $ps(197)=0.305$, $p<0.001$). Number of foot-tappings (41.17 ± 15.18) was inversely correlated with WHtR ($ps(191)=-0.155$, $p=0.016$) and % body fat ($ps(189)=-0.258$, $p<0.001$). There was no association between mentioned physical activity and health risk factors (arterial hypertension, overweight or obesity) or media consumption. Conclusions An increased number of foot-tappings was associated with favorable results of the analyzed cardiovascular risk factors, indicating the beneficial influence of physical fitness. However, the prevalence of overweight and obesity as well as arterial hypertension was already high in young athletes. It's alarming and underlines necessity for both, more screening programs for persons with ID like the Special Olympics Health Promotion Program as well as specific intervention programs to countersteer cardiovascular disease related health risks already at an early age. WORK RATES IN A WHEELCHAIR BASKETBALL GAME

RUPF, R., HATHAWAY, C.

Canadian Sport Institute Ontario

Introduction Work rates in wheelchair basketball have received little attention in the scientific literature. Average speeds and mobility movement remain the most studied parameters (Sporner et al, 2009; de Witte et al, 2015). However, how these metrics change over the course of the game remain unknown. The purpose of this study is to characterize the distance travelled, average speed, and high intensity efforts produced over the course of a wheelchair basketball game. Methods Distance travelled (DIST) and average speed (V) for 12 players was determined over 4 games during a Paralympic qualifying event, using the Catapult ClearSky system. High intensity efforts (HIE) were counted when athletes reached speeds above 60% maximal speed. Video analysis was performed, using SportsCode to track the time of every possession (POSS), and when the game clock was running (CLOCK) or stopped (DEAD) for 4 quarters (Q1, Q2, Q3, Q4). Timeframes from Catapult and Clearskey were merged, and only information for athletes on the court at any one time were tracked. Values displayed are averages of the 5 players on court. One way ANOVA, t tests, and pearson correlations were used for statistical analysis. Results Over the 4 games, DIST, V, and HIE was 5582 (328) m, 1.11 (0.03) m/s, and 273 (19) respectively. DIST is correlated to POSS ($r=0.8$, $p<0.05$), with average DIST per POSS equal to 37 (1) m. V and HIE was 100% and 180% greater during CLOCK than DEAD ($p<0.05$). V and HIE for each POSS was 1.41 (0.04) m/s and 2 (0.5) respectively. There was no difference from Q1 to Q4 for DIST, V, and HIE. The amount of time spent in CLOCK is 6% ($p<0.05$) lower than time spent in DEAD. Discussion The total work rates of wheelchair basketball players is strongly correlated to the number of possessions during a game. Further, work rates are stable over each quarter, suggesting the team is able maintain consistent efforts over the course of a game. This may be a result of increased rest time, with most of the game duration occurring with the game clock stopped. References de Witte AM, Hoozemans MJ, Berger MA, van der Woude LH, Veeger DH. (2016). J Sports Sci. 34. 811-820. Sporner ML, Grindle GG, Kelleher A, Teodorski EE, Cooper R, Cooper RA. (2009). Prosthet Orthot Int. 33. 210-217.

DEMANDS OF COMPETITIONS OF ELITE WOMEN WORLD CUP CYCLING RACES

SIAS, M., LA TORRE, A., MENASPÀ, P.

University of Milan

Introduction. Competition data are important to identify unique characteristics associated with successful performances. Elite women road cycling is a fast growing sport, however there is a lack of recent research (last 10 years) focusing on performances at International level. The aim of this study was to compare the physiological demands of recent women's World Cup races (2012-15) finishing with top 10 (T10) and out of top 10 (N-T10) results. Methods. Seven female professional cyclists (mean \pm SD; age: 28.5 ± 2.9 years; body mass: 55.7 ± 3.9 kg; height: 165 ± 4 cm) participated to this study. The participants' bikes were fitted with SRM powermeters. Forty-nine road World Cups (WC) were analysed, with 25 top T10 and 24 N-T10 race results. Race files were analysed with the open-source software GoldenCheetah. Descriptive statistics were used to report race characteristics such as length, duration and elevation gain. Maximal Mean Power curves (Quod et al. 2010) and % of total time spent in different power to weight bins (Martin et al. 2001) were compared in T10 and N-T10 with unpaired t-tests. Effect sizes were calculated and presented to allow a better interpretation of the results. The values 0.2, 0.5 and 0.8 were considered respectively small, medium and large (Sullivan et al. 2012). Statistical significance was set at $P<0.05$. Results. World Cups' average distance was 128 ± 7 km, with a duration of $3h20min\pm16$ min and a total elevation gain of 998 ± 551 m. The average power

recorded was similar with 184 ± 22 and 185 ± 16 W for T10 and N-T10, respectively. Maximal Mean Powers for durations between 10 and 600 s were significantly higher in T10 than in N-T10 ($P < 0.05$), with a large effect size for durations between 20 and 300 s. There was no difference in the % of total time spent below 0.75 W/kg (21 ± 4 and 19 ± 4 min for T10 and N-T10, respectively) ($P = 0.23$). T-10 spent significantly more time above 7.5 W/kg when compared to N-T10 (6 ± 2 and 4 ± 2 min, respectively) ($P = 0.005$), with a medium effect size. Discussion. In WC races Maximal Mean Power between 20 and 300 s were the main performance discriminant differentiating T10 and NT10.. Maximal Mean Power data found in this study were comparable to the data reported by Ebert et al. (2005) in top 20 WC races. The average power output found in this study was 10% higher than the power recorded in a previous study on domestic Australian competitions (Abbiss et al. 2010). Cyclists achieving T10 results spent more time above 7.5 W/kg when compared to N-T10, which seems to be a key factor determining the demands of T10 WC competitions. The findings of the present investigation should be considered for training prescription and selection purposes. Contact marco.sias@studenti.unimi.it

MODELLING PROFESSIONAL CYCLISTS' CAREERS WITH UCI POINTS

FILIPAS, L., GIORGI, H., LA TORRE, A., MENASPÀ, P.

University of Milan

Introduction. Retrospective analysis of road cycling race results can support long-term planning and be useful in the development of peak performances (Schumacher et al. 2006). To date, it is unclear when successful General Classification (GC) contenders achieve their first top 5 (T5) or top 10 (T10) result in the context of their cycling career. The main aim of this longitudinal analysis was to compare the careers of GC contenders before and after achieving a T5 versus T10 result using the Union Cycliste Internationale (UCI) point scoring system. Methods. Professional cyclists who achieved their first T10 GC result in a Grand Tour (Giro, Tour and Vuelta) between 2009 and 2014 were included in the analysis. This time frame was selected because it followed the introduction of the biological passport in 2008 and allowed for the inclusion of the UCI points scored during the year following each cyclist's first T10 performance. A period of 5 years, which included 3 years before and 1 year after the year of the first T5 or T10, was considered for the analysis. UCI points are available online and were collected at the end of 2015. Descriptive statistics were used to report demographic information, and t-tests were used to compare annual points aggregates, previous GT history and number of seasons as a pro cyclist in T5 and T10. Data were reported as mean \pm SD, and alpha was set to < 0.05 a priori for differences. Results. Riders achieved their first GC result at 28.5 ± 5.2 and 27 ± 3.8 years of age for T5 and T10, respectively. T5 group consisted of 71% Europeans, 18% South Americans and 12% North Americans; T10 group consisted of 83% Europeans, 9% South Americans and 9% North Americans. Riders scored more points in the season of a T5 finish (192 ± 73) than a T10 (146 ± 77) ($p < 0.05$). For both T5 and T10 the seasonal points were significantly lower in each previous seasons ($p < 0.05$). There were no differences in the number of GT participations (5.2 ± 3.9 and 3.5 ± 3.0 for T5 and T10, respectively), nor in the number of seasons as a pro cyclist (5.8 ± 3.7 and 4.7 ± 2.9 for T5 and T10, respectively). Discussion. Most of the subjects were European, which is unsurprising given that all the races and most of the teams were European. The average age at which cyclists achieved their first T5/10 result is similar to other endurance sports (Allen & Hopkins, 2015). Professional cyclists usually ride 3 Grand Tours before reaching a T10 finish. Interestingly, the seasonal progression to a top result was not gradual. After achieving the top result, riders maintained a stable level of performance and accumulated a similar number of UCI points during the following season. References. Allen SV, Hopkins WG (2015). COMPUTER SIMULATION MODELLING OF THE INFLUENCE OF DRAFTING ON COLLECTIVE BEHAVIOUR IN AN ELITE 10KM COMPETITIVE RUNNING EVENT

RENFREE, A.1, TRENCHARD, H.2, PETERS, D.M.1,3

1: University of Worcester, 2: Victoria, British Columbia, Canada, 3: University of Agder, Norway

Introduction Drafting in cycling has been shown to influence the collective behaviour of pelotons during competition (Trenchard, 2015). Whilst some evidence for collective behaviour in competitive running events exists (Hanley, 2015), it is not clear as to the extent to which this is determined by energetic savings conferred by drafting. Methods Using performance data from a men's elite championship 10k track running event, computer simulations were constructed using NetLogo 5.1 to test the effects of three different drafting quantities on collective behaviour: no drafting, drafting to 3m behind with up to ~8% energy savings (a realistic running draft); and drafting up to 3m behind with up to 38% energy savings (a realistic cycling draft). Three measures of collective behaviour were analysed in each condition; mean speed, mean group stretch (distance between first and last placed runner), and Runner Convergence Ratio (RCR) which represents the degree of drafting benefit obtained by the follower in a pair of coupled runners. Results Mean speed in the cycling draft condition (6.32 ± 0.28 m.s $^{-1}$) was higher than in the other conditions, but no significant differences were found between no draft (5.51 ± 0.13 m.s $^{-1}$) and runner draft conditions (5.57 ± 0.18 m.s $^{-1}$). Likewise, RCR was lower in the cycling draft condition, but did not differ between the other two. Mean stretch did not differ between conditions. Discussion It is suggested that collective behaviours observed in running events may not be fully explained through energetic savings conferred by realistic drafting benefits. They may therefore result from other, possibly psychological, processes. References Hanley B. (2015). Journal of Sports Sciences, 33(11), 1189-1195. Trenchard H. (2015). COMPARISON OF THE STANDARD ERROR OF THE ESTIMATES WHEN ESTIMATING CRITICAL POWER IN LABORATORY AND FIELD CONDITIONS

TRISKA, C.1,2, KARSTEN, B.3, TAZREITER, G.2, TSCHAN, H.1, NIMMERICHTER, A.2

1: University of Vienna (AUT); 2: University of Applied Sciences Wr. Neustadt (AUT); 3: University of Greenwich (UK)

Previous studies (2,3) have documented that Critical Power (CP) can be estimated validly and reliably under laboratory and field conditions. Under laboratory conditions, studies commonly employ time to exhaustion (TTE) tests using constant workloads. Contrary, field conditions commonly use time trials (TT), reversing dependent and independent variables. Several studies (e.g. 1) have shown that TTE have a lower reliability than TT. A recent study (3) demonstrated a high level of random of variations despite non-significant differences between the two conditions. This variation might have been caused by applying two methods (TTE vs. TT). The standard error of the estimate (SEE) of a regression that is used to estimate CP is a measure of accuracy. Therefore, the aim of this study was to compare the SEE between TTE estimated CP and TT estimated CP. After an initial graded maximal exercise test, ten participants (VO_{2max} 63.2 ± 5.5 mL/min/kg; Pmax 382 ± 38 W) performed three maximum effort prediction trials under both conditions using a single-visit protocol. In the laboratory, work rates leading to TTE within 2-15 min were estimated to be at 70%Delta, 98%Pmax and 110%Pmax. Under field

conditions participants had to produce highest possible power outputs over 12, 6, and 2 min. CP was estimated using a non-linear regression power vs. time (HYP) and two linear regressions work vs. time (LIN) and power vs. 1/time (INV). SEE between the conditions were compared using Wilcoxon signed rank tests. Descriptive results are presented as median (min; max) and statistical significance was set at $P < 0.05$. SEE values under laboratory condition were 1.45% (0.01; 7.60), 2.50% (0.01; 16.14), and 3.94% (0.01; 10.96) for HYP, LIN, and INV, respectively. SEE values under field conditions were 2.29% (0.59; 9.93), 1.38% (0.99; 11.63), and 3.12% (1.11; 11.7) for HYP, LIN, and INV, respectively. No significant differences were found for HYP, LIN and INV between the conditions ($Z = -0.178$; $P = 0.859$; $Z = -0.059$; $P = 0.953$; and $Z = -0.533$; $P = 0.594$). The results of this investigation show that the SEE is not influenced by the method chosen to estimate CP. Although the literature states that TTE are less reliable than TT, we conclude that estimating CP in a cohort of trained cyclists does not produce significantly different values of SEE.

INDIVIDUALIZED REFERENCE RANGES FOR THE ASSESSMENT OF FATIGUE AND RECOVERY IN COMPETITIVE ATHLETES

HECKSTEDEN, A., PITSCHE, W., MEYER, T.

Saarland University

Introduction Assessment of fatigue and recovery is essential for the daily fine-tuning of training load in competitive sports. However, large interindividual variability severely impedes on the diagnostic accuracy of fatigue indicators [1]. Individualization of reference ranges and joint consideration of selected parameters seem pertinent solutions to this dilemma. Therefore, we developed and evaluated an individualization algorithm based on a similar Bayesian rationale as the Athlete Biological Passport [2]. Beyond individualizing reference ranges for separate parameters, this procedure may also be generalized to the multivariate case. Method Urea and creatine kinase (CK) were selected as exemplary fatigue indicators [1]. Prior distributions and repeated measures standard deviations were characterized based on data of 883 squad athletes from different sports. Equations for the individualization procedure were adapted from previously published material [3,4] to allow for discrimination of 2 physiological states and ensure gradual approximation of intraindividual variability. Evaluation was carried out using data from 5 consecutive fatigue-recovery cycles in 14 elite junior swimmers and triathletes. Group-based reference ranges were derived from that same dataset to ensure a best possible group-based reference for comparison. Results Sensitivity was significantly higher with individualized reference ranges for CK ($p=0.013$) while a tendency towards significance could be demonstrated for urea ($p=0.068$). Numerical improvements in specificity failed to reach statistical significance in both cases. The success of individualization differed widely between athletes depending on the mean difference between fatigue states and intraindividual variability ('individual effect size'). Visualization of measured values together with the development of reference ranges over successive measurements offers an intuitive plausibility control for the individualization procedure and ensuing classifications. Discussion Assessment of fatigue and recovery based on individualized reference ranges for CK and urea offers higher diagnostic accuracy as compared to even a sample specific group-based approach. Additional benefit from multivariate applications and transferability to other parameters remains to be established. References 1. Hecksteden A, Skorski S, Schwindling S, Hammes D, Pfeiffer M, et al. INTERCULTURALITY IN SPORTS AS SOCIAL CHALLENGE – AN OVERVIEW OF THEORETICAL FOUNDATIONS AND EMPIRICAL RESULTS

GRIMMINGER, E.

TU Dortmund University

As sports is considered as one of the key motors of integration, sports organizations work since long time on concepts of integration of migrants into the existing sports system. Integration results in culturally heterogeneous groups that can be characterized by social hierarchies and social conflicts. To handle these social processes, an emancipatory, pedagogical approach is needed to create relationships between "the others" and "the us". Since long time, the concept of "Interculturality" is discussed as a possible approach to handle cultural diversity in social groups. The plenary session will give an overview of the theoretical foundations of this pedagogical concept, and will discuss its meaning for integration and intercultural processes in sports. The theoretical differentiation will show that "Interculturality" means more than just "integration in sports", as it reclaims equal participation and not only formal attendance. Thus, it may provoke conflicts and changes in the institutional context. To enrich the theoretical discussion, selected empirical studies of the research program "Interculturality in sports" (Gieß-Stüber & Grimminger) will be presented.

13:00 - 14:00**Conventional Print Poster****PO-CPP-04 Coaching & Adapted Physical Activity****THE RELATIONSHIP BETWEEN SPRINT PERFORMANCE AND VERTICAL AND HORIZONTAL PERFORMANCE TASKS IN FEMALE FIELD SPORT ATHLETES**

MONAHAN, M., PETRAKOS, G., EGAN, B.

University College Dublin

Introduction Sprint acceleration is a key determining factor of physical performance in field sports. This study primarily aimed to assess the relationship between 0-10 m (S10) and 0-20 m (S20) sprint acceleration and a range of vertical and horizontal performance tests. Secondly, the study aimed to assess if the strength of relationship between sprint acceleration and performance tests changed when just the fastest 10 participants were analysed. Methods Data was collected from female field sport athletes ($n = 21$). Vertical performance tests included a countermovement jump (CMJ), CMJ loaded with 50% of body mass (CMJ50), drop jump reactive strength index (DJ RSI) and an isometric mid-thigh clean pull (IMTCP). Horizontal performance tests included a horizontal jump (HJ) and a 5-repeated alternate leg bound (5RB). Results When the full cohort were analysed, S10 held a 'very large' relationship with HJ ($r = -0.73$) and 5RB ($r = -0.70$), a 'large' relationship with CMJ variables ($r = -0.61$ to -0.64) and a 'moderate' to 'large' relationship with CMJ50 variables ($r = -0.48$ to -0.62). When the fastest 10 participants were analysed, the strength of the relationship for both horizontal performance tasks increased (HJ, $r = 0.83$ and 5RB, $r = 0.75$), whereas no correlations between vertical performance tasks and S10 reached significance ($p > 0.05$). When the full cohort were analysed, S20 held a 'very large' relationship with HJ ($r = -0.79$), 5RB ($r = -0.75$) and CMJ variables ($r = -0.71$ to -0.75), a 'moderate' to 'large' relationship with CMJ50 variables ($r = -0.44$ to -0.63) and a moderate relationship with RSI ($r = -0.48$). When the fastest 10 participants were analysed, the strength of the relationship increased between S20 and 5RB ($r = -0.87$) and IMTCP rate of force development variables ($r = -0.63$ to -0.64). Furthermore, following assessment of just the 10 fastest players, HJ maintained a 'very large' relationship with S20 ($r = -0.73$) but no significant relationships were evident between S20 and CMJ, CMJ50 or DJ variables ($p > 0.05$). Discussion Horizontal jumping tasks are more predictive of sprint acceleration performance when compared to vertical jump and isometric force tasks. Furthermore, horizontal tasks are more predictive of sprint acceleration ability when just the fastest individuals are accounted for. Future research should investigate sprint acceleration and its longitudinal relationship with horizontal and vertical performance following training.

COUNSELLING OF COACHES ENHANCED BY SPORTS SCIENCE

WEBER, J., WEGNER, M., CHITTIBABU, B., FATULESCU, S.

CAU of Kiel

Introduction In sports games there is a frequent discussion how to transfer scientific findings into practice (Pfützner & Sell, 2007). Lemyre et al. (2007) state that formal programs are one way to develop coaching expertise while Cushion et al. (2003) name experience as a main source of coaches' knowledge. The aim of the study was to assess factors that enhance the coaches' expertise, research the coaches' rating of the playing-positions and additionally provide advice regarding position-specific performance of female elite handball players. Methods 52 coaches of female German have been questioned regarding their preference in developing handball-relevant performance factors (physical, technical, tactical, psychological) for position-specific performance and their coaching-biography while the corresponding players were tested in a complex test-battery concerning these factors. Results Coaches were only partially able to rate the position-specific demands for the tested factors. Coaches who formerly played as goalkeepers were able to rate the handball-specific demands for that particular position. In general, factors that enhance coaching expertise are positions formerly played, years spent playing and coaching, highest league played or coached and expertise as a former player. Discussion Coaching experience concerning position-specific demands can enhance practice and solve problematic decisions in everyday-training, e.g. to put inexperienced players on the wing player-position, to select halfbacks because of high body-height (Matthys, 2012) and selecting players for the goal because they lack physical fitness (Kajtna et al., 2011). A better knowledge of the position-specific demands based on scientific research and performance data are crucial to establish a recipient adjusted model to enhance practice and performance in handball teams. DIFFUSION OF THE LONG-TERM ATHLETE DEVELOPMENT MODEL IN CANADIAN COACHES

TRUDEAU, F.1, LAURENCELLE, L.1, BEAUDOIN, C.2, LAJOIE, C.1

1Université du Québec à Trois-Rivières; 2Université d'Ottawa

Introduction In 2005, Balyi and co-authors' Long term development of the athletes (LTAD) was integrated in the Canadian Sport Policy. Since then, more than 70 Canadian sport federations adapted LTAD to the reality of their sport and their athletes. The aim of this study was to document the process of adoption and implementation of LTAD by Canadian coaches. Methods We conducted an online questionnaire survey with Canadian coaches ($n = 574$; aged 35.2 ± 10.6 years) to understand the process of adoption and implementation of LTAD, we developed the questionnaire using the theory of diffusion of innovation (Rogers, 2003). Factors likely to influence adoption and implementation of LTAD were studied (e.g. perception of knowledge, anticipation of benefits, complexity, organizational constraints, etc.).

Results Differences appeared when the sample was divided according to different sports with a sufficient number of coaches for further analyses. Cross-country skiing coaches had the perception of knowledge of the higher LTAD (fair to good 61.1%), while among figure skating and gymnastics coaches this percentage was 18.4% and 10%. Beliefs in the efficacy of LTAD or anticipation of benefits were high among coaches in all sports studied. In soccer, figure skating, ice hockey, cross-country skiing and gymnastics coaches such fairly high to high expectations from LTAD are respectively 90.9%, 68.9%, 88.9%, 86.9% and 71.5%. A fairly-good to good perceived capacity to apply the principles of LTAD was highest among cross-country skiing 69.5%, and respectively 56.2% and 50% in soccer and ice hockey. However, only 30% and 26.6% of the gymnastics and figure skating coaches felt the same degree of capacity to apply the LTAD principles. Again, cross-country skiing coaches were only 4.3% to see LTAD implementation as rather complex or complex compared to more than 20% in all other coaches studied. No differences were observed between sports for organizational constraints. Discussion The majority of coaches in studied disciplines believed in the benefits and efficacy of LTAD to improve the performance of their athletes. However, the perception of knowledge and ability to apply the principles of LTAD show differences between the disciplines. These differences could be due: 1) to the type of disciplines i.e. late vs. early development, 2) the compatibility of LTAD with knowledge and performance requirements in each sport, and 3) the timing of our survey with the sports federation has developed and published its own LTAD. EFFECT OF A STATIONARY ARMCRANK PEDALING TRAINING PROGRAM ON THE LEVEL OF AUTONOMY , ANAEROBIC PERFORMANCE, SPIROMETRIC FUNCTION AND HEART RATE VARIABILITY IN PERSONS WITH TETRAPLEGIA

SINZ, S., BRIZUELA, G., ARANDA-MALAVÉS, R., MARTÍNEZ-NAVARRO, I.

Universidad de Valencia

Introduction It is accepted worldwide that physical exercise is good for everybody. But is it also good for persons with a high tetraplegia or would it harm them? And which sport would be good for them? Will it bring betterment to their physiological parameters or will it be detrimental to their health? Therefore, the aim of this study was to test handcycling as a suitable endurance sport and then analyze in a training program the parameters of spirometric function, heart rate variability and evaluate if there is any change to the level of autonomy. Methods The training consisted of a progressive arm crank pedaling (ACE) regimen twice weekly for 8 weeks with constant cadence and resistance of the participant's choice. We choose 11 participants (8 men, 3 women, 36.5 + 10 years of age and BM 72.3+13.4kg) with traumatic origin tetraplegia (5 with SCI between C4-C5 and 6 between C6-C7, Asia levels A and B) who had functional biceps and deltoid muscles but no triceps function and no hand grip ability. They could bend their elbows but not extend them against gravity or opposition. One week before and one week after the training program a QIF questionnaire (Field-Fote, 2009) was filled in, to measure the level of personal autonomy. A stationary Arm Crank Ergometer (Monarch) provided measurements of heart rate, spirometric variables and maximum arm pedaling power output (PPower). Results The results showed that participants with lower level SCI (C6-C7) presented higher QIF, PPOWER and pulmonary parameters than those with higher level (C4-C5) ($p < 0.05$). It also showed that the ACE training increased PPOWER, some spirometric variables and all indices of HRV. Nevertheless there was no significant change in the level of autonomy (QIF). In conclusion, an ACE short term training program is sufficient to meaningfully improve armcrank pedaling power, pulmonary function and heart rate variability in persons with cervical SCI, contributing to improve their muscular, pulmonary and cardiovascular function. Discussion We were able to conclude that over all the respiratory parameters have improved. And since respiratory problems are the primary cause for death of persons with a tetraplegia (Linn y cols, 2000) this is vital. Therefore persons with a tetraplegia should practice physical activity. Handcycling is a suitable physical activity for them which helps to improve respiratory values and therefore improves the live of persons with a tetraplegia. In our 8 week program we could not find changes in the level of their autonomy, but in a longer term study we could expect that participants gained more autonomy and positive experiences to joy up their lives through sport. BODY COMPOSITION ASSESSMENT IN SPINAL CORD INJURED WHEELCHAIR ATHLETES

CAVEDON, V., MILANESE, C., ZANCANARO, C.

SCHOOL OF EXERCISE AND SPORT SCIENCES

Introduction Adverse alterations in body composition (BC) are a potential risk for the health of subjects with spinal cord injury (SCI) and relevant to sport performance in wheelchair athletes (WA). This study investigated whole-body and regional BC in WA to assess differences between a) tetraplegic and paraplegic WA and b) WA and a larger sample of healthy males athletes. Methods Twenty-seven male WA aged 30.0 ± 9.4 with chronic SCI underwent dual-energy X-ray absorptiometry (DXA). One operator measured subtotal (total-body less head) and regional (arms, legs and trunk) body composition (lean mass [LM], bone mineral content [BMC], fat mass [FM] and fat mass percentage [%FM]). WA were split into two groups according to their level of injury as follows: tetraplegia (lesion above T1; Tetra, n=10) and paraplegia (lesion at T1 and below; Para, n= 7). Each WA was carefully matched to three healthy males athletes (n = 81) on the basis of DXA area and BMI. The t-test for independent samples was used to assess differences in the DXA outcomes between Tetra and Para as well as Tetra and Para and their respective control. Alpha value was set at 0.05 and p-values (pc) corrected for multiple comparisons were obtained with the Benjamini and Hochberg procedure. Results Tetra showed significant higher %FM vs. Para at the subtotal and regional level (.024

ROLE OF ADAPTED PHYSICAL ACTIVITY IN QUALITY OF LIFE, MOOD, SOCIALIZATION, BODY PERCEPTION OF PEOPLE WITH MULTIPLE SCLEROSIS

FRACCA, I.I, PERIN, A.S.2, LANZA, M.3

1Studio Prevenzione e Salute di Fracca Dott.ssa Ilaria, 2Master in Preventive and Adapted Physical Activity, University of Verona,

3Department of Neurological, Biomedical and Movement Science, Verona U

Introduction The main aim is retrospectively evaluate the psychological and social benefits of an intervention of Adapted Physical Activity (APA) for people with multiple sclerosis (MS). Methods Thirteen patients with MS who walk independently or with support (EDSS 1÷6, autonomous in posture transition from the supine to the upright position and vice versa) have agreed to undergo a APA program for 10 lessons of 60 minutes, following AISM Guideline, and to perform a protocol of daily exercises at home. The assessment of the training

effectiveness was carried out with a retrospective questionnaire (42 Items - Likert scales 0 - 10). Results Most of the subjects (69.2 ±100%) reported medium or high improvements in the control of posture, in gait, in speed of locomotion, in joint mobility, in manipulation, in breathing, in balance, in coordination, in lymphedema and in bladder control. The 83,1% of them reported psychological and social benefits, improvements in the mood (average score for items 6,6/10), cheerfulness, well-being, self-esteem, body perception, quality of life. The 92,3% of the subjects reported high improvement in group socialization (score 8,1/10). The 76,9% said they had adopted a more active life style after training period; the 84,6% declared that they engage in daily physical activity and the 84,62% have increased physical activity after the lessons. Discussion/Conclusion Results tend to confirm the role of Adapted Physical Activity to improve quality of life, mood, socialization, body perception for people with MS. As they have a long life expectancy and high risk of depression, it is important for them and for their loved ones, to make it as good as possible. It is reasonable to hope that future research will have to focus on the quantitative and qualitative role of exercise, as it may increase exercise prescription. References Jack S. Burks, Kenneth P. CARDIOVASCULAR ADAPTATION TO EARLY SPORT ACTIVITY IN RECENT SPINAL CORD INJURY SUBJECTS

MERATI, G., RIZZATO, L., GAMBIRASIO, C., RAMPICHINI, S., SPINELLI, M., VEICSTEINAS, A., REDAELLI, T.

University of Milan

Introduction In recent spinal cord injury (SCI) the cardiovascular auto-regulation may be particularly challenging (due to peripheral blood pooling and the lack of communication between cardiovascular receptors and autonomic effectors), especially during exercise, in which heart rate (HR) must compensate for the reduction in stroke volume. Physical training is known to benefit resting HR and its adaptation to exercise, but such effects have been studied mainly on long-term stabilized SCI. As training is currently being proposed in early rehabilitation of SCI ("sport-therapy"), our aim was to study HR adaptation to a physical training program in recent SCI patients. Methods Resting HR, HR variability (HRV) and HR response to exercise (graded exercise test) were evaluated by ECG and HR monitor in a group of recent (<3 months, on average) SCI subjects (n=30; 23 males, age 35+-12 yrs), further divided in 2 sub-groups, based on lesion level (higher than T6 [HT6, compromised sympathetic heart innervation], n=14; lower than T6 [LT6, intact heart innervation], n=16). Patients were evaluated: 1) at admission in the rehabilitation center; 2) after 2 months of training (resistance activity on adapted ergometers + aerobic sport activity, 3-4 sessions/wk); 3) 6 months after discharge. Results Resting HR showed different adaptations to training between groups, remaining stable in time in HT6 subjects (p=ns vs pre-training condition) and monotonically increasing in LT6 patients. Training significantly increased in all patients the maximal load achieved during the graded exercise (p<0.05 vs pre-training conditions). However, the HR/load relationship improved more efficiently in the LT6 group. As regards HRV, the typical parasympathetic HRV indexes (e.g. RMSSD, HF power, etc.) in time and frequency domains showed a reduction in time in LT6 patients only. The benefit of training on HR was lost after 6 months of follow-up in HT6 patients and maintained in LT6 individuals. Discussion The effect of recent SCI on resting morning HR differed with the lesion level, confirming previous data. Early after a SCI, HR, its autonomic control and its adaptation to exercise changed, probably due to a cardiovascular autonomic compensatory adaptation. An apparent regain of orthosympathetic system seemed to occur, which needs further elucidation. Early sport-therapy induced a better adaptation of HR to physical work in LT6 SCI patients, which remained stable after a 6-months follow-up. Particular attention may therefore be paid to follow and motivate the upper level SCI patients to practice over time. References Hopman M.T. et al. SECULAR TREND IN MENTAL HEALTH AMONG ADOLESCENTS IN NATURAL DISASTER AREAS

SUZUKI, K., OKAZAKI, K., SASAKI, K., SAKAMOTO, Y.

Juntendo University

Introduction The build environment related to physical activity in adolescents was drastically changed by The Great East Japan Earthquake in 2011. The Growth and Health Longitudinal Study in the town of Onagawa was begun six months after the Great East Japan Earthquake of 2011. The town of Onagawa suffered heavy damage from the earthquake and tsunami. Our study group has already reported on physical activity trends among children and adolescents in the town of Onagawa (Okazaki et al., Prev Med Rep. 2015; 2: 720-4). Numerous studies have also shown that exposure to disasters is correlated with mental health. A relatively small number of studies have employed longitudinal assessments enabling clarification of changes in mental health. The purposes of this study were 1) to clarify the secular trend of mental health among adolescents living in a town affected by the earthquake and tsunami in 2011, and 2) to examine differences of relations between the mental health and physical activity profiles of each year. Methods The participants were junior high school students aged 11-13. Five surveys were conducted in the town of Onagawa at about six months (n = 195), one year (n = 160), two years (n = 175), three years (n = 148), and four years (n = 156) after the natural disaster. Survey items included health-related quality of life (HRQL, the 23-item Pediatric Quality of Life Inventory Version 4.0 Generic Core Scales, Varni et al., Ambul Pediatr. 2003; 3(6): 329-41), and whether or not students engaged in sports club activities after class. A two-way ANOVA (F1: time, F2: sex) was used to examine secular changes of HRQL. A Cohen's d was used to calculate the size of the effect of sports club activity at each time point. Results The results of a two-way ANOVA showed there was no significant interaction (p = .987) between time*sex. A significant difference was found only for the sex factor (F1, 824) = 47.47, p = .000), and the total score of HRQL for boys was higher than for girls (pooled mean: 83.7+-12.5, 77.4+-13.4, respectively). The pooled mean for girls was especially low compared to a previous study (83.7+-13, reported by Varni et al., 2003). There was not a significant secular change (p = .692) in HRQL. The effect size between the sports club group and non-sports club group

in the first year ($d = 3.54$) was clearly higher than the other time points. Conversely, the fourth year ($d = 0.52$) was smallest in all time points. Conclusions These findings might suggest the following: 1) the mental health level of adolescents living in natural disaster areas has not changed since the disaster, 2) the mental health level of adolescent girls is lower than boys, 3) the effect of sports club activity was the highest in the first year, and the effect reduces over time. This study was supported by the Japan Society for the Promotion of Science (Grant-in-Aid for Young Scientists A: 24680065).

ASSOCIATION BETWEEN HAND GRIP STRENGTH AND PHYSICAL FITNESS TEST PERFORMANCE FROM A LARGE SAMPLE <10-18 YEARS> OF HUNGARIAN SCHOOL CHILDREN

KARSAI, I.1, KAJ, M.2, CSÁNYI, T.2

1: University of Pécs, Medical School (Pécs, Hungary), 2: Hungarian School Sport Federation (Budapest, Hungary)

Introduction The hand grip strength test (HGST) is a widely used method to estimate the general functioning of the human musculoskeletal system, the measurement is simple and can be done at any age (Roberts et al., 2011). The achieved values can be linked to actual health status and effects of lifestyle which is why it is often used in epidemiological studies (Saint-Maurice et al., 2015). Professional literature describes several physical test batteries to determine specific muscle profiles of different populations (athletes, school children, workers and the elderly) but the association between the HGST and those test performances is still not clear. The aim of the present study is to provide further information about the link between HGST and other test performances. Methods Data was collected according the NETFIT system (Csányi et al., 2015) in Hungary during the physical fitness assessment period of the 2014/15 school year (192 702 girls, 190 256 boys). Groups were defined by gender and age. Correlation coefficients (CC) were calculated between the test results of the HGST and the curl up (CU), push up (PU), standing long jump (SLJ), trunk lift (TL), backsaver sit and reach (BSR) and predicted VO_{2max} of PACER (PVO₂). Results There is a wide variability across gender and age groups in the values of the CC between HGST and the involved parameters but with all groups the TL with acceptable r values typically ranges between 0.106 -0.173 ($p<.001$) and the SLJ typically ranges between 0.157 -0.302 ($p<.001$). Discussion While many daily functions and sporting events require high activity levels of the flexor musculature of the forearms and hands and, except sitting and reclining, any kind of physical activity requires muscle involvement from the locomotor muscles and from the trunk muscles which are responsible for maintaining the equilibrium of the upper body, the link between HGST and TL, SLJ can be explained with a higher level of activation of the muscles which are also activated in the linked tests. According to these findings, the HGST can itself be a good indicator of sedentary versus physically active life style for 10-18 age groups. PROFILE IN PHYSICAL FITNESS IN CHILDREN AGED 3-6 YEARS

TORRES-LUQUE, G., FERNÁNDEZ-GARCÍA, A.I., CABELO-MANRIQUE, D., NIKOLAIDIS, P.T.

University of Jaén

PROFILE IN PHYSICAL FITNESS IN CHILDREN AGED 3-6 YEARS Introduction The importance of physical activity for health is well known and research has noted both physical and psychological benefits when children participate in physical activity (Ahn and Fedewa, 2011; Janssen and LeBlanc, 2010). Are a few studies have focused on analysing the physical abilities and fitness level of children aged 3-6 years (Latorre et al., 2015; Ortega et al, 2015). The aim of this study is determined physical condition, equilibrium and coordination in children 3-6 aged years. Methods 296 children of 4.10 ± 1.75 years are selected. An anthropometrics (weight, height, BMI, waist circumference), balance (Flamingo Balance Test and Walking Heels Raised), coordination (Crawling and Bouncing ball), and finally the physical fitness (strength, endurance and speed) were evaluated. The IBM SPSS v.20.0 (SPSS, Chicago, USA) software was used to perform the statistical analysis. Data were expressed as mean and standard deviations of the mean (SD). Results The results show the next values in anthropometrics: weight (18.93 ± 4.08 kg); height (108.54 ± 8.35 cm); BMI (15.92 ± 1.91 kg/m²), WC (55.11 ± 8.36 cm). Coordination: crawling (13.95 ± 6.43 s); and bouncing ball (8.07 ± 5.37). Physical fitness: handgrip right hand (4.12 ± 2.49 kg), handgrip left hand (3.97 ± 2.49 kg), horizontal jump (80.24 ± 27.50 cm), resistance (261.31 ± 65.99 m), speed 5-m (1.61 ± 0.32 s), speed 25-m (7.77 ± 1.87 s). Discussion Are few studies than study physical fitness, but then have similar values of this study (Sugihara et al., 2006; Latorre et al., 2015). This study has novel data on balance and coordination in children. This information would be of great practical importance for teachers, offering them a test handy and inexpensive solution. Taking into account the above information, is necessary more investigation in preschool children. References Ahn, S., Fedewa ,A.L. (2011). A MULTILEVEL ANALYSIS OF CHILDREN AEROBIC FITNESS

MAIA, J., GOMES, T., PEREIRA, S., REYES, A., BACCIOTTI, S.

Faculdade de Desporto - Universidade do Porto

A MULTILEVEL ANALYSIS OF CHILDREN AEROBIC FITNESS Maia, J.1, Gomes, T.1, Pereira, S.1, Reyes, A.1, Bacciotti, S.1 1: FADEUP (Porto, Portugal) Introduction Children aerobic fitness (AF) is expected to change with age. Since children spend most of their daily awake time at school, it is expected that it may favour AF development. This study aims (1) to describe children AF increases with age, (2) together with the joint effects of gender (GE), physical activity (PA) body mass index (BMI), (3) as well as school size (SZ). Methods Sample comprises 1057 Portuguese children (547 girls) aged 8.53 ± 1.36 yrs from 23 primary schools. AF was assessed with the time to run/walk 1-mile (1M), PA with the Godin-Shephard questionnaire, and BMI from height and weight. School size was marked by number of students. Reliability (R) was estimated. Since children are nested within schools, a multilevel model was used: Model 1 included child predictors (age, GE, PA, BMI); Model 2 added SZ. Parameters maximum likelihood estimates (b) were computed in SuperMix software. Results Data was reliable in all variables ($R>0.70$). Schools explain 9% of the total variance in AF. Older children are more aerobically fit – less time to cover the 1M

($b=-0.50 \pm 0.04$, $p<0.05$); girls, on average, run the 1M in 12.13 min; boys run in less time ($b=-1.11 \pm 0.11$, $p<0.05$), as well as those with greater PA ($b=-0.005 \pm 0.002$, $p<0.05$), but those with greater BMI take more time to cover the distance ($b=0.14 \pm 0.02$, $p<0.05$); SZ had no significant ($p>0.05$) effect on children AF. Discussion Few studies investigated the school role in children AF. Similar to Zhu (1997), AF is also explained by the school-level characteristics. Older children have higher AF given that they run fast the 1M (Zhu, 1997). Consistent with our findings, sex-differences exist in AF favouring boys during middle and late childhood (Malina et al, 2004); further, more physically active children are more likely to increase their AF (Lamme et al, 2012; Zhu et al, 2010). On the contrary, heavier children tend to have lower AF because the test requires propelling the body on a horizontal axis (Malina et al, 2004). Although SZ was not an AF significant predictor, the between schools variance suggests that other school context characteristics may be related to it. References Lamme L, Worth A, Bos K (2012). PHYSIQUE AND PHYSICAL STRENGTH IN BOYS WITH DIFFERENT LEVELS OF FAT ACCUMULATION AND BMI-ANALYSIS ON SOUTH KOREAN JUNIOR HIGH SCHOOL STUDENTS -

TANAKA, N.1, FUJII, K.2, SAITO, Y.3, SHO, M.4

1: TGU (Miyoshi, Japan), 2: AIT (Toyota, Japan), 3: NZU (Komaki, Japan), 4: NUAS (Nishin, Japan)

INTRODUCTION According to an analysis of previous studies demonstrated that body fat has an effect, although slight, on physical strength during puberty. However, there are no reported investigations of physical strength characteristics depending on differences in level of fat accumulation by body fatness type among individuals. In the present study, in addition to categorizing body types by BMI, we also determined level of fat accumulation, and investigated physical strength in 9 different body types in South Korean boys. METHODS The subjects were 201 first-year junior high school boys, in whom height, weight, BMI, fat mass, body fat percentage, and soft lean mass were measured. Items of physical strength measured were sit and reach, 20 m shuttle run, push-ups, and sit-ups. A mean value evaluation method was applied to determine standards for judging body fatness by BMI. To determine the level of fat accumulation, a standard regression evaluation chart was constructed for body fat percentage with respect to BMI. Evaluation zones with five levels were established in the standard regression evaluation chart. Using the determinations of BMI and fat accumulation, the subjects were classified into the 9 groups. RESULTS The results showed a clear trend for height to increase as BMI became greater. However, the height of boys with excessive accumulation of fat tended to be short and not to differ greatly regardless of BMI type. In muscle endurance, it was found that physical strength evaluations were similar in people with little fat accumulation in the BMI obese group and people with much fat accumulation in the BMI normal or slim groups. In general endurance ability, it was found that physical strength evaluations were similar in people with little fat accumulation in the BMI obese group and people with much fat accumulation in the BMI slim group. DISCUSSION In the present study, excluding the groups with the characteristic of excessive fat, the 9 groups showed a tendency for higher body fat percentage when height was taller. Furthermore, the present finding of short height in students with excessive fat regardless of whether BMI was high or low has not been reported previously. In physical strength items, the results suggest that even if BMI is low, muscular endurance of the upper limbs or trunk and endurance ability will be low if there is a high level of fat accumulation. The subjects with low BMI in the present study were late matures; in other words, it is thought that level of maturation affects elements of muscular endurance of the upper limbs or trunk and endurance ability in the growth period. ACTIVE VERSUS PASSIVE TRANSPORTATION TO SCHOOL: HEALTH MOMENT IN THE SCHOOL.

MARTINEZ-MARTINEZ, J.

University of Castilla La Mancha

Introduction Health status is related to the physical activity we do and in particular how to move in the middle. So, this study examines the physical activity levels of children and adolescents based on compliance with international health recommendations, and establishes the relationship between it and the transport used to access school. Methods The sample of this study consists of a total of 455 subjects (247 girls and 208 boys) 9 years old, who participated in the European Youth Heart Study (EYHS) in Spain. It was selected by a process subjects stratified cluster in public, charter and private schools of the urban semi-urban and rural areas, Community of Madrid. AF data were collected by the accelerometer GT1M of Actigraph. As inclusion criteria the existence of records for at least four days was established with a minimum of 10 hours per day recorded as directed by Riddoch et al. (2004) Results The results show as the population tested does comply with international recommendations for healthy physical activity (girls 62.28; 85.81 children, minutes / day) with differences between boys and girls; also it shows how the active transport to school can contribute to comply levels of physical activity (3.10; 3.56 minutes / day). Discussion The World Health Organization (WHO, 2010) established the current international PA recommendations for health. They established that children and adolescents should engage in at least 60 min of PA from moderate-to-vigorous intensity (MVPA) daily. El viaje activo es una forma excelente de incorporar más ejercicio en la rutina diaria, y así lo demuestran estudios como Mota et al. (2007) o el informe EURYDICE (2013). Our study shows that active transport may be very important to comply with international health recommendations, so it is an excellent opportunity for children to be active as they can reach the center by bicycle or foot. so it contributes to the accumulation of minutes to implement these recommendations and the recommended steps. ARE MODERATE AND VIGOROUS INTENSITY ASSOCIATED WITH CHILDREN'S SELF-PACED PHYSICAL ACTIVITY RELATED TO HEALTH AND FITNESS OUTCOME?

MOGHADDASZADEH, A., ALLARD, S., BELCASTRO, A.N.

York University

INTRODUCTION: Children's self-paced physical activity (SPA) is associated with ranges of energy expenditures (EE) and percentages of moderate-vigorous intensity (%MVPA) in a simulated environment. The purposes of this study were to determine: a) if a program approach using children's SPA exhibits a range of EE and %MVPA; and b) if children's physical activity levels (PAL) are related to changes in body composition (i.e., weight; body mass index (BMI); waist circumference (WC); sum of 6 skinfolds (SSF6)) and cardiorespiratory fitness (CRF) variables (i.e., systolic and diastolic blood pressure (SBP, DBP); resting heart rate (HRr); and aerobic power (estimated VO_{2max})). **METHODS:** Thirty-three children (age 9.8±1.3 years; weight 43.1±13.4 kg; BMI 20.8±3.2 kg/m²), registered in a community recreation centre, were recruited to participate in a SPA (guided active play) program for 8 weeks (4x/week; 1hr/d). Daily PA was assessed (using ActiGraph GT3X+ accelerometer) with EE and %MVPA estimated using regression equations from calibrated ACC (using CosMed2 oxygen collections system). All other variables weight, BMI, WC, SSF6, SBP, DBP, HRr and aerobic were measured following standard procedures (all within ± 3.5% coefficient of variation). Statistical procedures were performed using ANOVA and/or Pearson Correlation 'r' (SPSS 22.0). **METHODS:** Children's SPA averaged 280±47 kcal/session, 5.6 kcal/min and 4.1±0.6MET across the 8wks. The average time spent in sedentary and MVPA were 23 ±11% and 39 ±14%, respectively. The changes (pre-post) for WC (+1.1cm), SSF6 (+4.2mm), DBP (-5.4mmHg), SBP (-4.5mmHg), and VO_{2max} (+2.3mLO₂/kg-1/min-1) were significant. Following the program a 5% increase in aerobic power and a 4.5% and 9.0% decrease in resting systolic and diastolic blood pressures, respectively, were observed ($p<0.05$). When these changes are compared to the time spent at %MVPA, no relationship was evident ($p>0.05$); however SBP, DBP and VO_{2max} had an improving trend with greater %time spent in both %MVPA and %VPA (effect sizes of -0.45, -0.71 and 0.43, respectively). **CONCLUSION:** children's SPA programs promote EE and %MVPA sufficient to modify important health and fitness variables, which may result in improved health benefits for children.

THE EFFECTS OF A NINE MONTH INTRADIALYTIC EXERCISE PROGRAM ON FUNCTIONAL CAPACITY AND FATIGUE SYMPTOMS IN HEMODIALYSIS PATIENTS

GIANNAKI, C., GRIGORIOU, S., KARATZAVERI, C., STEFANIDIS, I., SAKKAS, G.

University of Nicosia

Introduction Hemodialysis (HD) patients suffer from generalized weakness, exercise intolerance and muscle atrophy and disturbed sleep, all leading to a generalized fatigue and a lack of energy (Sakkas and Karatzaveri, 2013; Giannaki et al., 2014). It is noteworthy that one third of HD patients report that they feel worse in the immediate hours after the end of HD session while one out of four patients reports severe or very severe intensity of fatigue after the end of the HD session (Gordon et al., 2011). In addition, post- HD fatigue has been reported to be associated with physical inactivity (Gordon et al., 2011). According to our knowledge, no data exist regarding the effects of chronic exercise training on post-HD fatigue. The aim of the current study was to assess the effectiveness of a nine month intradialytic exercise program on fatigue symptoms occurring during and after the HD session as well as on functional capacity in patients receiving HD therapy. Methods Twenty stable HD patients participated in the study (59±13.7 years; 16 males). All participants completed a 9-month supervised exercise training program during the HD session (3 times weekly). Fatigue, sleep quality, depression levels and daily sleepiness status were assessed via validated questionnaires, while functional capacity assessed by a battery of tests, before and after the intervention period. Results After the nine month aerobic exercise training intervention, exercise capacity increased by 65% and functional capacity by an average of 40%. Regarding the post dialysis fatigue questions, patients reported feeling better post HD after 9 months of exercise training program. Finally, overall fatigue symptoms were found to be significantly improved. Discussion Our study showed that a 9-month aerobic exercise training program improved both functional capacity and exercise capacity, followed by an improvement of the general perception of fatigue and by a reduction in the severity and the duration of post-HD fatigue symptoms. Exercise training could be considered as a safe and effective non pharmacological approach to ameliorate fatigue symptoms in HD patients. THE EFFECT OF INTERMITTENT HYPOXIC TRAINING ON BLOOD ANTIOXIDANT STATUS IN SWIMMERS

POPRZECKI, S.

Academy of Physical Education

Do not insert authors here Introduction Training in hypoxic conditions has become an important element of preparing elite athletes for major competitions. However, both physical exercise and hypoxia can lead to increased cellular and tissue oxidative stress and defense antioxidant system. The main objective of this study was to examine the effect of simulated intermittent normobaric hypoxia during the land training of swimmers on the induction in oxidative stress and the antioxidant defense system. Methods The study included 23 male swimmers divided into hypoxic (HG, n=14) and normoxic groups (NG, n=9). The HG performing part of their land training (3 x 1.5 h = 4.5 h per week for 3 weeks), under simulated intermittent normobaric hypoxia (O₂ = 15.5%; corresponding to an altitude of 2,500 m a.s.l., LOS-HYP-1/3NU, LOWOXGEN ® SYSTEMS, Ger), but NG in normoxia condition. The swim training program was similar for both groups and included 9 training units per week in normoxia. Blood was drawn before and after the initial and final training units. In blood was determined: the oxidative stress marker (MDA), enzymatic (CAT, SOD, GPx, GR) TAS level and non-enzymatic (GSH, UA) antioxidants also activities of CK and LDH. Results Hypoxia condition of swimmers land training insignificantly differentiated of oxidative stress marker MDA, level of TAS, enzymatic and non-enzymatic antioxidant defense system. However variable "training" had significant effect on MDA level and GR, CK and LDH activity. Similarly had significant effect on UA and TAS level. Discussion Antioxidant defense system in blood to countered effects of oxidative stress is complex in nature and consist with multiple factors such antioxidants (Rodriguez et al., 2007). We observed a relatively minor alteration of blood antioxidants in the swimmers during training in hypoxia condition. Correspond to a mild induction of oxidative stress in these athletes (Truijens et al. 2002). Other authors, like Bailey et al. (2001), Pialoux et al. (2010), Rodriguez et al. (2007) were observed, that, training with IHT programme had significant effect for generating oxidative stress and stimulated antioxidant status in athletes. In conclusion, short training program of swimmers at normobaric hypoxia condition (2,500 m a.s.l., 4,5 h a week for 3 weeks) combined with sea-level training had insignificant effect for oxidative stress and antioxidant status in blood of competitors. LONGITUDINAL CHANGES IN MUSCLE SIZE AND FUNCTION DURING A 5 YEAR FOLLOW UP STUDY IN OLDER MEN AND WOMEN

CAMERON, J.1, DEGENS, H.1, MCPHEE, J.1

1: Neuromuscular and Skeletal Ageing Research Group, Manchester Metropolitan University, United Kingdom.

Introduction In order to help older people to live independently and actively for longer we need to understand the physiological processes of muscle wasting leading to clinical syndromes of sarcopenia and weakness. The typical approach to this very important issue simply compares physiological measurements between young and old, but secular and lifestyle differences between young and old may confound these comparisons. Longitudinal studies are needed in order to directly measure the physiological changes in the same people over a period of several years. **Methods** We followed up 35 older individuals aged 71 ± 4 yrs at baseline, repeating the original protocol five years later. Knee extensor muscle size was measured from Magnetic Resonance Imaging (MRI), with torque and neural activation assessed from voluntary contractions and the interpolated twitch technique. **Results** After 5 yrs, torque was 9% lower (151 ± 41 N.m vs 138 ± 43 N.m; $p < 0.01$), muscle cross-sectional area fell by 6% (53.4 ± 12.7 cm 2 vs 50 ± 10.4 cm 2 ; $p < 0.01$), Neural activation decreased by 5% ($90.5 \pm 5.1\%$ vs $85.1 \pm 7.6\%$; $p < 0.01$). **Discussion** These results indicate that muscle weakness in septuagenarians occurs principally due to reduced strength per unit muscle mass, this was also accompanied in part by a reduction in neural control. Future work will complete more detailed assessments looking into changes in muscle specific tension and mobility. Contact J.Cameron@mmu.ac.uk

AGE-RELATED INCREASE IN MUSCLE DEFORMABILITY OF THE RECTUS FEMORIS: RELEVANCE TO SARCOPENIA

TANAKA, F., ATES, F., KAWAKAMI, Y.

Waseda University

Introduction Age-related muscle loss (sarcopenia) has been widely recognized. Thigh muscles, the quadriceps in particular, are known to demonstrate outstanding sarcopenia [1]. There is also some evidence of an increase in noncontractile tissues within a muscle by aging [2], which can change elastic properties of a muscle [3]. We tested the hypothesis that such age-related changes in muscle might be associated with deformability of a muscle upon mechanical loading, in a cross-sectional study design. **Methods** Fifty-six healthy males and females (17 males and 39 females with age ranging from 41 to 81 yr; no significant gender difference in age) participated. Cross-sectional images of the rectus femoris (RF) were taken with B-mode ultrasonography while a participant stood at rest. At the midthigh level, an ultrasonic probe was applied onto the skin in the transverse direction to RF in 2 conditions, 1) without any compressive force (N) and 2) with pushing force in the direction from the mediolateral center of RF to that of the femur, up to when no more RF deformation occurred (P). The RF muscle thickness (anteroposterior distance between fascial borders) and width (mediolateral distance between fascial borders) were measured in the recorded images, and RF cross-sectional area was evaluated. In addition, the ratio of thickness (P/N) was calculated as an index of deformation. Pearson product-moment correlations and unpaired t-tests (between genders) were performed with the level of statistical significance at $p < 0.05$. **Results and discussion** The RF cross-sectional area was negatively correlated with age ($r = -0.30$), showing the sign of sarcopenia. The deformation index (P/N) was also correlated negatively with age ($r = -0.42$) and with RF cross-sectional area ($r = 0.33$). These results suggest that RF deformability upon mechanical loading increases (RF becomes more compliant) with aging. The deformability is related to its size (smaller RF more compliant) but the higher correlation of P/N with age suggests factors other than size, e.g. infiltration of adipose tissues into muscle [3]. Further analysis is currently under way on the same subjects to evaluate intramuscular fat content. **Acknowledgments** This work was partially supported by Council for Science, Technology and Innovation (CSTI), Cross-ministerial Strategic Innovation Promotion Program (SIP), "Technology for creating next-generation agriculture, forestry and fisheries" (funding agency: Bio-oriented Technology Research Advancement Institution, NARO). **References** 1) Porter, M.M. et al. CIRCULATING miRNAs AS EARLY BIOMARKERS OF SKELETAL MUSCLE DENERVATION IN RATS

SIRACUSA, J.1, KOULMANN, N.1,2, CHAPUS, C.1, VERRET, C.1, BOURDON, S.1, GORIOT, M.E. 1,3, BANZET, S.1,3

1 Institut de Recherche Biomedicale des Armees, Breteigny-sur-Orge, France ; 2 Ecole du Val-de-Grace, Paris, France ; 3 INSERM U 1197, Clamart, France.

Skeletal muscle loss is a common feature in a variety of diseases and a result of prolonged inactivity or aging. Recently, circulating muscle-enriched miRNAs have been shown to be biomarkers of muscle damage, but whether they could be markers of early muscle loss is unknown. Our aim was to evaluate the use of single and combinational measurements of circulating miRNAs in the early diagnostic of muscle loss in a denervation model in rats. Skeletal muscle denervation was induced by the section of the soleus muscle nerve (DNV, $n = 32$). Blood samples were drawn 6 h, 12 h, 24 h and 48 h post-denervation in DNV or sham operated rats (SHAM, $n = 32$) as well as in a control group (CON, $n = 12$) to measure miR-1-3p, -133a-3p, -133b-3p, -206-3p, -208b-3p, -499-3p, -378a-3p and -434-3p by RT-qPCR. The diagnostic accuracy of each individual miRNA was assessed by a receiver-operating characteristic (ROC) curve analysis and the resulting area under the curve (AUC). DNV rats were considered positive, SHAM and CON were considered negative for muscle remodeling. Then, we sought to optimize the diagnostic accuracy by using a logistic regression analysis with a backward selection to identify the best miRNAs combination. We found no significant alterations of the circulating levels of miR-1-3p, -206-3p, -499-5p and -378a-3p in DNV and SHAM rats, while miR-208-3p remained undetectable in most samples. Both miR-133a-3p and -133b-3p significantly increased at 12 h in DNV group compared to SHAM (1.9 and 3.3-fold, respectively) with a peak value at 24 h (3.5 and 5.2-fold, respectively), and returned to baselines at 48 h. MiR-434-3p transiently increased 6 h after the sham-operation but not in DNV. The ROC curve analysis

revealed that miR-1-3p and -206-3p had the lower diagnostic accuracy (AUC = 0.528) while miR-133a-3p (AUC = 0.723) and miR-133b-3p (AUC = 0.856) had the higher. By using a logistic regression, we identified a model combining miR-133b-3p + miR-206-3p. This model was able to discriminate almost perfectly denervated rats from non-denervated rats as shown by the AUC = 0.947. In conclusion, we describe that individual circulating miRNAs could be useful biomarkers of early muscle remodeling in response to denervation. Furthermore, the combination of multiple biomarkers is an efficient strategy to greatly improve the diagnostic accuracy.

THE NEED FOR EMG NORMALIZATION METHODS FROM A CLINICAL PERSPECTIVE

KRATZENSTEIN, S., SCHAEFKE, H.

Christian-Albrechts-University of Kiel

Introduction Normalization of electromyographic (EMG) data is an essential process to limit the influence of external factors such as electrode replacement within longitudinal studies (Soderberg & Knutson, 2000). However, none of these methods seem suitable for clinical applications, due to patients' limited ability of motion. Previous studies investigated the analysis of normalization methods as well as the analysis of absolute data and suggest that normalization may not always necessarily be required. Both approaches seem to be capable to provide at least fair reliability. However, a direct comparison is still lacking. Thus, this study targets at the quantification of electrode replacement effects and reliability, and the benefit of normalization methods compared to the analysis of absolute data. Methods 13 recreational cyclists (5m/8f, 22–28 years) performed 1 min cycling trials (150–170W; 90 rpm, Cyclus 2) on 3 consecutive days. Electrode placement was orientated to recommendations by Hermens et al. (2000) but extended by the application of a parallel pair of electrodes. While one pair was regularly replaced between the measurements, the other was kept permanent. EMG data (Myon 320, prophysics AG) were determined for m. vastus medialis (VM) and m. tibialis anterior (TA). RMS was calculated for every test cycle. The effect of electrode replacement was then quantified comparing signals from permanent and regular setups. Intra-session (Split-Half) and inter-session reliability (intra-class-correlation) were calculated to assess reproducibility of myo-electrical signals. For normalization, a functional 10 s T-V test and a static 5 s MVC were applied. Results Internal consistency was found to be excellent ($r = 0.98$). The permanent electrode set-up resulted in higher ICC values (VM: 0.86, TA: 0.88) compared to regular electrodes application (VM: 0, TA: 0.82). Normalization of VM signals led to higher ICCs (MVC: 0.66, T-V: 0.91), while TA signals remained at the same level of reliability (MVC: 0.86, T-V: 0.76). Discussion Permanent set-ups are recommended for electrode placement. They led to higher reproducibility due to avoidance of electrode replacement. In clinical settings, it will save time and simplifies the physiological demands to the patients. If permanent set ups are not feasible, normalization is still a key aspect of EMG measurements. Nonetheless, it was not possible to clearly examine a preference for either T-V or MVC normalization, based on this study's results. It is suggested that the optimal normalization method depends on the patient's motion abilities and the respective muscle task. References Hermens HJ, Freriks B, Disselhorst-Klug C, Rau, G (2000). PROTECTIVE EFFECTS OF QUERCETIN SUPPLEMENTATION ON MUSCLE DAMAGE AND NEUROMUSCULAR IMPAIRMENT INDUCED BY ECCENTRIC CONTRACTIONS

PATRIZIO, F., CECI, R., DURANTI, G., SGRÒ, P., FELICI, F., SABATINI, S., DI LUIGI, L., SACCHETTI, M., BAZZUCCHI, I.

Università degli Studi di Roma "Foro Italico

INTRODUCTION It is well known that eccentric muscle contractions, cause structural damage of muscle cells, which increases the production of free radicals, oxidative stress, inflammation (Myburgh, 2014; Dartnall et al, 2011). This disruption leads to a decline of muscle strength and it is associated to modifications of the electromyographic (EMG) activity of the affected muscles in the days after the exercise (Turner et al., 2008). This study examined the potential protective effect of quercetin (Q), a potent antioxidant and anti-inflammatory, on altered muscle contractile properties induced by eccentric exercise. METHODS 16 healthy young subjects were randomly assigned, in a double-blind crossover design, to start with either 1000 mg of Q or with a placebo (PLA) for 14 days before and for 7 days after performing voluntary eccentric muscle actions of the elbow flexors. Elbow flexors' strength and surface electromyography (sEMG) were recorded in both isometric and isokinetic (30, 60, 120, 240 °/s) contractions. Mean fibre conduction velocity (MFCV) was estimated from the sEMG from the biceps brachii. Indices of muscle damage, soreness, elbow angles, swelling and measures of plasma concentration of creatine kinase (CK) and lactate dehydrogenase (LDH) were taken at baseline, PRE and POST exercise, and 24, 48, 72, 96 h and 7 days after exercise. RESULTS Eccentric exercise induced an acute muscle damage as evidenced by significant increases observed for all indices. Differences between treatments were detected in strength loss, MFCV, muscle pain and in elbow angle after exercise. The PLA treatment induced greater decreases in maximal voluntary isometric contraction (MVIC) and in MFCV (33% and 9.9% on average, respectively) than the Q (22.5% and 2.7% on average, respectively) after exercise. Torque-angular velocity curve was lower in PLA (33% on average) than Q treatment (28% on average) at all time after exercise. Similarly, the decrease of MFCV value at all angular velocities ($P < 0.05$) was more pronounced in the PLA (6.5% on average) than Q (1% on average) conditions. At 72 and 96h the PLA treatment had greater increases in CK and LDH than Q. DISCUSSION These data show a protective effect of Q supplementation on markers of muscle damage and inflammation after eccentric exercise. Q seems to be able to attenuate the loss of contractile function and to potentially contribute to ameliorate the recovery of maximal force capacity. (Dartnall et al, 2011). NEUROMUSCULAR FUNCTION OF THE QUADRICEPS MUSCLE IN GONARTHROYSIS PATIENTS

MAU-MOELLER, A.1, JACKSTEIT, R.1, FELDHEGE, F.1, WEIPPERT, M.2, HUSMANN, F.2, MITTELMEIER, W.1, BADER, R.1, SKRIPITZ, R.1, BEHRENS, M.2

University of Rostock

Introduction Knee osteoarthritis (KOA) is commonly associated with a dysfunction of the quadriceps muscle which contributes to alterations in motor performance [1]. However, the underlying neuromuscular mechanisms of muscle dysfunction are not fully understood. The main objective was to analyse how KOA affects neuromuscular function of the quadriceps muscle during isometric maximal, submaximal and fatiguing voluntary contractions. Methods Twenty patients and 20 healthy controls participated in this cross-sectional study. The following parameters were assessed: (i) isometric maximal voluntary torque (IMVT) and neuromuscular activation (average EMG) (ii) position control, i.e. joint position sense (mean absolute error) at 30° and 50° of knee flexion, (iii) torque control, i.e. accuracy (mean

absolute error), absolute fluctuation (standard deviation), relative fluctuation (coefficient of variation) and periodicity (mean frequency) of the torque signal at 20%, 40% and 60% of IMVT, (iv) EMG-torque relationship at 20%, 40% and 60% of IMVT and (v) fatigue resistance (time to task failure) at 40% of IMVT. Results Patients produced significantly lower IMVT (-60.0% ; $p = 0.001$) accompanied by reduced average EMG of the rectus femoris (-33.5% ; $p = 0.046$). The knee joint repositioning error was significantly higher at 30° (143.6% ; $p = 0.001$) and 50° (147.9% ; $p < 0.001$) of knee flexion in patients. The mean absolute error of the torque signal was significantly higher in the patient group at 20% and 40% of IMVT by 96.6% ($p = 0.034$) and 101.5% ($p = 0.044$), respectively. The SD and MNF of the torque signal were significantly reduced at all three torque levels in patients. Furthermore, patients had 27.0% greater CV ($p = 0.079$) at 20% of IMVT whereas no differences could be found at 40% and 60% of IMVT. EMG-torque relationship was decreased for the vastus lateralis at 20% and 40% of IMVT by 64.1% ($p = 0.006$) and 33.1% ($p = 0.016$), respectively. Between-group differences in the EMG-torque relationship could only be documented for the vastus lateralis at 20% and 40% of IMVT with higher average EMG values (64.1%; $p = 0.006$ and 33.1%; $p = 0.016$, respectively) in the patient group. Patients produced significantly shorter time to task failure (-51.1% ; $p = 0.049$) during sustained submaximal fatiguing contraction. Discussion This study has shown that KOA is not only associated with a deterioration of torque and neuromuscular activation during isometric maximal voluntary contractions, but also with an impaired position and torque control at submaximal torque levels, an altered EMG-torque relationship and a higher fatigability of the quadriceps muscle. 1. DEVELOPMENT AND VALIDATION OF AN EXERCISE DEVICE FOR USE IN AN LBNP BOX

BAPTISTA, R., SUSIN, T.B., BENYOUCEF, Y., DAILEY, C., NEVES, A.M.B.S., RUSSOMANO, T.

Pontifical Catholic University of Rio Grande do Sul and Naval Research Laboratory, Washington, DC, USA

INTRODUCTION: The LBNP box is widely used to study cardiovascular physiology, orthostatic intolerance and responses to exercise. An exercise multiplatform (ENTIRETY) was constructed for use in an LBNP box. The study evaluated physiological responses and perceived exertion (RPE) during 5 min of exercise using ENTIRETY in supine and standing positions. **METHODS:** Six subjects (28.8 ± 10.9 yr, 64.8 ± 11.2 kg, 163.2 ± 6.9 cm) had heart rate (HR), oxygen consumption (VO_2), carbon dioxide production (VCO_2), respiratory exchange ratio (RER), electromyography of the VL and VM muscles (sEMG), and Borg scale RPE measured at rest and during exercise in both body positions. **RESULTS:** Increased HR during the 5 min exercise was not affected by body position. However, a decrease in VO_2 and VCO_2 (29.34 ± 22.79 ml/kg/min; 26.30 ± 6.66 ml/kg/min) mean measurements for the supine position in comparison to the orthostatic position (14.2 ± 4.45 ml/kg/min; 18.40 ± 4.55 ml/kg/min) ($P < 0.05$) was observed. The mean RER showed no significant difference between the supine (1.16 ± 0.37) and standing (1.28 ± 0.11) positions. The mean RPE was higher in the supine position (6.67 ± 2.83 points) than in the standing (4.83 ± 2.85 points) ($P < 0.05$). Comparison of the sEMG showed higher average activation of the VM and VL muscles in the supine position (18.88 ± 5.15 mV; 14.88 ± 6.09 mV) than in the standing (12.62 ± 4.25 mV; 8.42 ± 3.45 mV) ($P < 0.05$). **DISCUSSION:** Performance of exercise while standing requires a greater metabolic response due to the effect of gravity on the individual at the Gz axis, which is decreased in the supine position. These results are in accordance with findings from the scientific literature and therefore validates the use of the ENTIRETY exercise device in LBNP studies. Thus, ENTIRETY could present greater potential of use for muscle and cardiovascular conditioning, when individuals exercise in supine and standing positions, respectively.

EFFECT OF PELVIC TILT ON ABDOMINAL MUSCLE ACTIVITY DURING ABDOMINAL HOLLOWING -AN ULTRASONIC SHEAR WAVE ELASTOGRAPHY STUDY-

SHIMIZU, I., TATEUCHI, H., MOTOMURA, Y., MORISHITA, K., MASAKI, M., KATO, T., KUSANO, K., ICHIHASHI, N.

Kyoto university

Introduction The abdominal hollowing technique is commonly used to preferentially recruit the transversus abdominis (TrA) for individuals with low back pain in clinical practice (Hodges et al., 2003). However, selective contraction of TrA is difficult even with visual feedback using ultrasound B-mode (Urquhart et al., 2005). The purpose of this study was to clarify the effect of pelvic posterior tilt on abdominal muscle activity during abdominal hollowing. Methods Nineteen healthy men participated in this study. Participants were instructed to perform pelvic posterior tilt or maintaining pelvic position neutral with/without abdominal hollowing. To measure the muscle tension, the shear elastic modulus of the four anterior trunk muscles: rectus abdominis(RA), external oblique(EO), internal oblique(IO) and TrA was calculated using ultrasonic shear wave elastography. To determine differences in shear elastic modulus of each abdominal muscles, two way repeated measures analysis of variance (pelvic tiltSpine, 28, 2594-2601. CYTOKINES LEVELS IN HIPPOCAMPAL FORMATION OF RATS SUBMITTED TO DIFFERENT EXERCISE MODELS

ARIDA, R.

Federal University of São Paulo

Introduction: Cytokines are cell-signalling proteins secreted in order to mediate the response of the body's defence system to injury and to regulate diverse inflammatory processes. Investigation with rats has shown that aerobic exercise can alter brain levels of inflammatory cytokines (Gomes da Silva et al., 2013). However, little is known whether other types of exercise (e.g., resistance exercise) can provide similar effects. In this way, we evaluated the hippocampal levels of cytokines in rats submitted to resistance, voluntary or forced exercise. **Methods:** Forty Wistar rats were divided into the following groups: control, resistance exercise, voluntary exercise and forced exercise ($n=10$ rats for each group). Rats of exercise groups were submitted to exercise programs over 25 consecutive days. Twenty-four hours after last exercise session, rats were decapitated, hippocampi dissected and interleukin 10 (IL10), interleukin 6 (IL6) and tumour necrosis factor alpha (TNF α) quantified by multiplex microbead immunoassay. One-way ANOVA, followed by Tukey post hoc tests were utilized to compare the results. **Results:** Voluntary and forced exercise did not induce alterations in hippocampal cytokines (IL-6, IL-10 and TNF α) levels ($p > 0.05$). Compared to control rats, resistance exercise increased IL6 ($p = 0.009$) and IL6/IL10 ($p = 0.001$) ratio, and decrease the TNF α ($p = 0.013$) levels. **Discussion:** Inflammatory cytokines can exert negative or positive effects on brain function. These effects are dependent on numerous factors including the type of cytokine produced, the functional state and type of stimulated cells, and also concentration and duration of exposure to the cytokines. We demonstrated that aerobic exercise at low intensities does not alter brain inflammatory cytokines. Considering that IL-6 can have a dual effect (Spooren et al., 2011) and it can also inhibit TNF α release (Benveniste et al., 1995; Shrikant et al., 1995), it is possible that elevated levels of IL-6 induced by resistance exercise may have reduced hippocampal TNF α levels. In sum, our findings indicate for the first time a possible favourable effect of resistance exercise on hippocampal reduction of pro-inflammatory cytokine TNF α . FUNCTIONAL AND CORTISOL RESPONSES AFTER EXERCISE INDUCED MUSCLE DAMAGE IN HUMANS

PAPADOPETRAKI, A.1, KOLLIAS, L.1, MOUSTOGLIANNIS, A.2, MARIDAKI, M.1, PHILIPPOU, A.2

National and Kapodistrian University of Athens

Introduction The skeletal muscle is being forcibly lengthened while generating active tension during eccentric exercise, which can cause muscle damage (Philippou et al. 2009). Various functional and systemic responses have been described as a result of eccentric exercise-induced muscle damage. The purpose of this study was to investigate cortisol response and functional outcomes after an eccentric exercise protocol (Nosaka et al. 2002) particularly modified for the lower extremities. **Methods** Six male volunteers (age: 24 ± 3 years, height: 179 ± 3 cm, mass: 82.42 ± 10.8 kg) performed 8 sets of 6 maximal eccentric actions of the knee extensors muscles of one leg. Baseline measurements including maximum strength, perceived muscle soreness evaluation (palpation and flexion-extension), and jumping performance (counter-movement jump (CMJ) and drop jump (DJ)) were performed in each leg 2 days prior to eccentric exercise, immediately after (0h), as well as 48h and 96h post exercise. Blood samples were collected at baseline and 48h after the eccentric exercise, while all measurements and blood sampling took place between 9.00 and 10.30 a.m. Student's T-test for cortisol, and one-way ANOVA with repeated measures and Tukey's post hoc test were used for statistics. Results Eccentric exercise protocol resulted in a loss of muscle force by 47%, 42% and 31% at 0h, 48h and 96h post-exercise, respectively. Performance in DJ and CMJ was also impaired; maximum height in DJ was reduced by 33%, 28%, 26% at 0h, 48h and 96h, respectively, ($p < 0.05-0.01$), while in CMJ the maximum height decreased by 15%, 18%, 11% at 0h, 48h and 96h post-exercise, respectively ($p < 0.05-0.01$). The participants reported significant muscle soreness, i.e. 17.8mm, 25.8mm and 13mm in a 100mm visual analogue scale at 0h, 48h and 96h post exercise, respectively ($p < 0.05-0.01$). Serum levels of cortisol increased by 37% 48h after the eccentric exercise protocol. **Discussion** The findings of this study indicate that the eccentric exercise protocol used resulted in muscle damage, as reflected by the prolonged muscle force loss and the delayed onset muscle soreness post-exercise (Nosaka et al. 2002). Interestingly, the muscle damaging protocol also led to a prolonged impairment of the jumping performance, potentially attributable to neuromuscular dysfunction of the damaged muscles. Moreover, the perturbation in circulating levels of cortisol may be indicative of an inflammatory activity and subsequent muscle degradation following eccentric exercise-induced muscle damage (Miles et al. 1994). EFFECTS OF HYPEROXIA ON MUSCULAR ENDURANCE

KOJIMA, Y., FUKUSAKI, C., ISHII, N.

The University of Tokyo

Introduction A number of studies have shown that hyperoxic environment can enhance the aerobic endurance, whereas its effect on the muscular endurance has not been well understood. This study investigated the endurance performance, activation level and tissue oxygenation in the working muscle during repeated weight-lifting tasks in the hyperoxic environment. **Methods** Ten healthy young men performed repetition of one-hand preacher curl at an intensity of 30%1RM until exhaustion in two separate sessions: one was under normoxic condition (20.9%O₂) and the other under hyperoxic condition (30.0%O₂). Each session was conducted on a different day in randomized order. During the exercise, electromyographic activity (EMG) and oxygenation level of the biceps brachii muscle were measured with surface electrodes and near-infrared spectroscopy (NIRS), respectively. Root mean square (RMS) of EMG was normalized to that at the maximal voluntary contraction. In NIRS, changes in oxygenated, deoxygenated, and total hemoglobin levels from those at rest, and tissue oxygenation index were analyzed. All of these values were averaged for five repetitions. Since the maximal number of repetition varied with subjects and oxygen conditions, the mean values for the first, middle and last five repetitions were compared between hy-

peroxic and normoxic conditions. Results The maximal number of repetition under the hyperoxic condition was significantly larger than that under the normoxic condition. For all parameters relating to muscle activation and oxygenation, two-way analysis of variance tests showed no significant effects of oxygen concentration (normoxia vs. hyperoxia), but significant time effects (the first, middle, and last five repetitions). Significant interaction effects were found in RMS of EMG, oxygenated hemoglobin level, deoxygenated hemoglobin level, and tissue oxygenation index. Multiple comparison tests showed that only RMS of EMG during the last five repetitions was significantly larger under normoxia than under hyperoxia. Discussion These results indicate that hyperoxia can improve muscular endurance by delaying the fatigue-induced elevation of muscle activation. However, the muscle oxygenation level may not be related to this effect. Intramuscular H₂O₂ during exercise is lower under hyperoxic condition than normoxic condition (Eiken and Tesch, 1984; Adams and Welch, 1980), which could cause the positive effects of hyperoxia on muscular endurance. THE EFFECTS OF RUNNING AN ULTRA TRAIL RUN OF 130 KILOMETERS – A CASE REPORT

WEGMAYR, C.

Wilhelminenspital

Introduction Data on the impact of ultra-marathons on the concentration of novel cardiovascular biomarkers are scarce. A study of 16 experienced runners, who completed a 60 km ultra-marathon, could show significant changes in copeptin and midregion pro-adrenomedullin concentrations (I). We sought to report echocardiographic, electrocardiographic and laboratory changes of established and novel biomarkers in a young female participant of an endurance trail run. Results Immediately after the run a significantly prolonged QT (410ms) and QTcB (457ms) interval was found. NT-proBNP concentrations increased from 61 ng/L at baseline to 834 ng/L and 138 ng/L at the time point 1 and at the time point 2, respectively, whereas troponin I levels remained below the upper limit of normal. With respect to novel cardiovascular biomarkers, we observed a clinically significant elevation of copeptin levels to 11.47 pmol/L. Discussion The main finding in this case was that despite an uninterrupted run of 130 km, the elevation of the above mentioned markers were clinically significant but modest in extent. Particularly, troponin I elevation did not occur at any point in time, whereas markers of cardiac stress, such as NT-pro-BNP and copeptin did increase above the ULN. Repolarization changes in electrocardiography and apical hypokineses in the right ventricle resolved after a recovery period of 34 hours. References (I) Lippi G, Schena F, Salvagno GL, Sanchis-Gomar F, Guidi GC. Serum copeptin and midregion proadrenomedullin (MR-proADM) after an ultramarathon. MUSCLE OXYGENATION CHANGES DURING THE EXERCISE AND THE RECOVERY PHASES OF REPEATED SPRINTS OF DIFFERENT DURATIONS

SMILIOS, I.1, POLYMERAKOU, E.1, BOGDANIS, G.C.2, TOKMAKIDIS, S.P.1

1. Democritus University of Thrace, 2. National Kapodistrian University of Athens

Introduction Muscle metabolism is dependent upon sprint duration and is greatly challenged during the execution of multiple sprints. Based on sprint duration, muscle oxygen availability, oxygen extraction and oxygenation levels during repeated sprints may affect muscle metabolism and fatigue. Thus, the purpose of this study was to examine the changes in muscle oxygenation levels during exercise and recovery phases of repeated sprints of short (5 s), moderate (10 s) and long duration (20 s). Methods Twelve males (age: 21.3±2.1 yrs) performed three protocols of repeated sprints on a cycle ergometer. The first protocol included the performance of 12 sprints of 5 s duration with 50 s recovery, the second 6 sprints of 10 s duration with 100 s recovery and the third 3 sprints of 20 s duration with 200 s recovery. Using near infrared spectroscopy, the range of changes of oxyhemoglobin (O2Hb), deoxyhemoglobin (HHb) and Hb difference (Hbdiff) of VL were measured during each sprint as well as during the first 30 sec of recovery. Results Mechanical power decreased by 11.2±8.2, 19±6.4 and 16±4.9% during the 12x5, 6x10 and 3x20 s sprints, respectively. During the exercise phases of the 12x5 s protocol, the range of increase of HHb progressively narrowed ($p < 0.05$) while there were no changes ($p > 0.05$) in the range of decrease of O2Hb and Hbdiff. During the exercise phases of the 6x10 s and the 3x20 s protocols, the range of decrease of O2Hb and Hbdiff was augmented ($p < 0.05$) while there was no change ($p > 0.05$) at the range of increase of HHb. During the first 30 s of recovery phases at the 12x5 s and the 6x10 s protocols the increase of O2Hb and Hbdiff, and the reduction of HHb progressively declined ($p < 0.05$). At the recovery phases of the 3x20 s protocol, the increase of O2Hb declined ($p < 0.05$) while the increase of Hbdiff and the decrease of HHb remained stable. Discussion Muscle oxygen availability and oxygenation levels remain stable during short duration repeated sprints while oxygen extraction decreases. Though, during moderate and long duration repeated sprints, oxygen availability and oxygenation levels decrease whereas oxygen extraction remains stable. Furthermore, duration during the recovery phases among sprints of either short or moderate, muscle oxygen availability and oxygenation levels decrease while oxygen extraction increases. Among long duration sprints, oxygen availability decreases although oxygen extraction and oxygenation levels do not change. It appears that sprint duration differentiates the mechanisms used to respond to the metabolic demands of a repeated sprint exercise session regardless of the fact that total exercise duration (60 s) and exercise to rest ratio (1:10) are similar. EFFECTS OF NITRATE ON O₂ COST OF EXERCISE IN HEALTHY ELDERLY MEN

DAL SACCO, L., CALABRIA, E., SPIGOLON, G., COLOSIO, A., CAPELLI, C., TAM, E.

University of Verona

Introduction Many studies report the beneficial effects of nitrate supplementation (NO₃-) in improving exercise tolerance and in reducing the energy cost of exercise in young adults. However, age, muscle fiber type and fitness level may affect the effect of NO₃- on the cost of muscular exercise. Aging, f.i., may deteriorate vascular integrity and responsiveness, lead to muscle weakness and exercise intolerance and may therefore weaken the beneficial ergogenic effect of NO₃- . The aim of this study was to investigate whether NO₃- may be effective in decreasing the energy cost of exercise in healthy elderly men. Methods The study was a double blind, randomized, controlled, crossover design, with 8 days beetroot juice (BJ) supplementation (NO₃- - 8-mmol NO₃-/day) or nitrate-depleted BJ as placebo (PL - 0.8-mmol NO₃-/day). At this time, 5 males (68.8±5yr; 77.3±10kg; 172.2±6.3cm; V' O₂max 39.2±4.2mL/kg/min) have completed the study. Breath-by-breath O₂ uptake kinetics (Quark PFT, Cosmed, IT) was evaluated before (B) and after (A) intervention during two square wave transitions on cycle ergometer (Excalibur Sport, Lode, NL) at a mechanical power corresponding to 80% of GET (Low Intensity - LI) and to 50%Δ (50% of the difference between GET and V' O₂max - High Intensity - HI). Transitions lasted 6 min each, were followed by 6 min rest

and were repeated in three different days. After four weeks of washout, the treatments were crossed and the tests repeated. The data of three transitions were averaged and time aligned. At LI, the average values of the last 30s were taken at rest and in the last min of transition. At HI, average values (30s) were taken at rest, in the 3rd and 6th min of exercise. Results During HI exercise, the V' O₂ slow component amplitude decreased by 11% in NO3- (2.17 ± 0.30 l/min (B) and 2.14 ± 0.22 l/min (A) ($P < 0.05$); it remained the same with PL (2.16 ± 0.19 l/min (B) and 2.16 ± 0.21 l/min (A)). Steady state O₂ uptake during LI decreased by 6% with NO3- (1.18 ± 0.34 l/min (B) and 1.09 ± 0.25 l/min (A). With PL, it amounted to 1.16 ± 0.26 l/min (B) and 1.13 ± 0.30 l/min (A) (NS). Discussion In spite of the paucity of the subjects (the study is still ongoing), preliminary results suggested that NO3- significantly reduced the V' O₂ slow component amplitude during severe-intensity exercise, but had smaller effects on O₂ cost of moderate-intensity exercise. A better O₂ delivery to O₂ utilization ratio in the exercising muscles may be the potential responsible of the observed effects. References Grassi B, Rossiter HB, Zoladz JA, Exerc. Sport Sci. Rev., Vol. 43, No. 2, pp. 75Y83, 2015 Breese BC, McNarry MA, Marwood S, Blackwell JR, Bailey SJ, Jones AM, Am J Physiol Regul Integr Comp Physiol, 2013. 305 (I2): p. R1441-50. EFFECT OF PALM PRE-COOLING WITHOUT NEGATIVE PRESSURE ON ENDURANCE PERFORMANCE IN HOT ENVIRONMENT

MASUDA, Y.1, SAKAI, S.1, SAHO, Y.2, HIROSE, N.3, FUKUAYASHI, T.3, NAKAMURA, C.3

1) Graduated School of Sport Sciences, Waseda University 2) Faculty of Medical Technology, Teikyo University 3) Faculty of Sport Sciences, Waseda University

Introduction The palm pre-cooling techniques with the negative pressure have shown the preventive effect on increase core temperature during exercise, consequently, the positive effect on the endurance. Unfortunately, from practical point of view, the device which provides the negative pressure is not affordable especially for the team sports. Furthermore, the effect of the palm pre-cooling without negative pressure which is much easier to apply has not been proven yet. The purpose of this study was to examine the effect of the palm pre-cooling without negative pressure on endurance performance in hot environment. Methods Subjects were seven male well trained collegiate rugby players. Subjects randomly completed two trials before exercise; the 15min pre-cooling (PC) by touching icing pad (10°C) palms without negative pressure and the no pre-cooling (CON) with crossover design. After either PC or CON, subjects started the 40min cycle exercise at 60% VO_{2max} (EX1) in hot environment (30°C, 60%RH), then continued cycling at 80% VO_{2max} to exhaustion. Before, during and after exercise, tympanic temperature (Tty), heart rate (HR), blood pressure (BP), time-to-exhaustion(TTE), and Rating of Perceived Exertion (RPE), Visual Analog Scale (VAS) were measured periodically as the physiological and subjective fatigue parameters, respectively. Result Although BP was kept comparatively low at the initial 20min of EX1, and TTE was comparatively longer in PC, there were no statistically significant differences in TTE, Tty, HR, BP, RPE and VAS between PC and CON. Discussion Contrary to the many evidences on the positive effect of the palm pre-cooling with the negative pressure, the results of this study did not show the same effect. The application of the 15min pre-cooling time and the without negative pressure were thought to be the main reasons for the result. As previous studies indicated, longer cooling time than 30min would be necessary for the effective palm pre-cooling. Palm pre-cooling without negative pressure may lead to the vasoconstriction in palm so that the forearm blood circulation was restricted. In conclusion, the negative pressure is essential for palm pre-cooling. References Wegmann M, Faude O, Poppendieck W, Hecksteden A, Fröhlich M, Meyer T(2012).Sports Med.Jul 1,42(7):545-64. EFFECTS OF ENDURANCE EXERCISE AND PDTC ON SKELETAL MUSCLE ENERGY METABOLISM GENE EXPRESSION IN RATS FED A HIGH-FAT DIET

HU, M., HUANG, H., XIE, Y., LIAO, B.

Guangzhou Sport University

Objective: Nuclear factor-kappa B (NF-κB) signaling pathway is the master regulator of chronic inflammation, which is a risk factor of insulin resistance. However, it is still unclear that whether NF-κB signaling pathway involves in the exercise-induced improvement of energy metabolism. The aim of this study is to investigate the effects of endurance exercise combined with the PDTC (inhibitor of NF-κB) on skeletal muscle protein gene expression involved in energy metabolism in rats fed high-fat diet (HFD). Materials and methods: Twenty-four male SPF rats fed with HFD for 6 weeks were randomized into 4 groups (n=6 in each group): HFD group (H group), HFD+exercise group (HE group), HFD+PDTC (HP group), HFD+exercise+PDTC (HEP group). The rats in HE group and HEP group were performed the exercise training for 4 weeks from the 8th week on and those in HP group and HEP group received the intraperitoneal injection of the PDTC with the dose of 80mg/kg/day for 2 weeks from the 10th week on. After this, the glucose tolerance test and insulin tolerance tests were performed, and the activity of skeletal muscle mitochondria oxidative enzyme and protein gene expression involved in energy metabolism were measured. Results: Both exercise and PDTC reduced content of body fat and the ratio of body fat weight/body weight in HFD rats. PDTC impaired exercise-induced increase of extensor digitorum longus (EDL) weight/body weight in HFD rats. In addition, PDTC increased fasting plasma triglyceride in HFD rats; Exercise improved glucose tolerance, and both exercise and PDTC improved insulin tolerance in HFD rats, but PDTC had no significant effects on glucose tolerance; Exercise significantly improved the activities of succinate dehydrogenase (SDH) and cytochrome C oxidase (COX) in EDL of HFD rats, but PDTC attenuated the exercise-induced increase of COX activity in EDL of HFD rats; PDTC significantly increased mRNA expression levels of uncoupling protein 2 (UCP2) and peroxisome proliferator-activated receptor coactivator-1α (PGC-1α), but PDTC blocked exercise-induced increase of COX4 mRNA in EDL of HFD rats. Discussion: Previous studies showed that exercise can improve mitochondrial function in skeletal muscle and reduce inflammation. We found that inhibiting NF-κB signaling can be beneficial to HFD rats. However, our study showed that PDTC attenuated mitochondrial adaptation to endurance exercise in male HFD rats, which is similar to the changes in female chow rats (Feng et al, 2013). Our results indicated

that NF- κ B signaling pathway is also necessary to exercise-induced mitochondrial adaptation in HFD rats. Reference Feng H, Kang C, Dickman J, et al. Exp Physiol, 2013, 98:784-95 Contact whoomin@hotmail.com

CARBOHYDRATE SUPPLEMENTATION ALLEVIATES NEUROMUSCULAR FATIGUE DURING PROLONGED CYCLING

DEKERLE, J., KERN, J., NUNN, M., SHAFFER, L., TUCKNOTT, A., TWOMEY, R.

University of Brighton

Introduction The neuromuscular fatigue induced by prolonged cycling has both peripheral and central origins (Thomas et al., 2015). This could be manipulated by carbohydrate (CHO) availability. We assessed the effect of CHO supplementation on exercise tolerance, rate of perceived exertion (RPE), and neuromuscular functions during heavy-intensity exercise. **Methods** Nine trained cyclists (age: 29 ± 9 , weight: 78 ± 5 kg, peak VO₂: 3.9 ± 0.6 l·min⁻¹) exercised to exhaustion at $69 \pm 4\%$ of peak VO₂ (SRM ergometer, Germany) twice (single-blinded): Ingestion of 1) a non caloric sweet placebo solution (PLA), 2) a 12% CHO solution (90g CHO.h⁻¹ in 150 ml per 15 min; 2:1 glucose:fructose ratio). Before, at minutes 60 and 90, at exhaustion for PLA (EXH: 130 ± 31 min) but matched EXH time for CHO (ISO), responses to transcranial magnetic stimulation and supramaximal electrical femoral nerve stimulation were obtained to assess corticospinal and neuromuscular function, respectively. Capillary blood glucose and lactate concentrations, and RPE were also recorded. **Results** No trial-difference was found pre-exercise. Blood glucose was systematically greater ($+1.5$ mmol.l⁻¹) with a lesser decrease throughout CHO (end values: 4.0 ± 0.3 vs 3.0 ± 0.3 mmol.l⁻¹). RER was also greater during CHO ($.89 \pm .04$ vs $.88 \pm .03$). With no trial-difference, blood lactate concentration decreased significantly from minute 60 (around 2.3 mmol.l⁻¹) to 90 (around 1.9 mmol.l⁻¹) and did not change thereafter (around 1.5 mmol.l⁻¹ at end-exercise). With similar RPE values at minute 60 (around 13), RPE increased more slowly during CHO (end values: 16 ± 1 ; EXH-PLA: 18 ± 2). For the right knee extensors, exercise induced reductions in maximum voluntary contraction (MVCs; CHO:-7%; PLA:-13%), potentiated twitch force (CHO: -18%; PLA: -17%) and peripheral voluntary activation (CHO: -5%; PLA: -7%) with greater MVCs for CHO ($P < 0.05$). There was no discernible pattern for voluntary activation from stimulation of the motor cortex. **Discussion** Exogenous CHO supplementation increases CHO availability and utilisation during exercise, and reduces the perception of effort for a given sub-maximal work rate. With no difference in peripheral fatigue, the greater force-generating capacity of the knee extensors post-exercise supports CHO supplementation enhancement of exercise tolerance. However, alleviation of fatigue mechanisms upstream from the neuromuscular junction could not be confirmed using transcranial magnetic stimulation. THE USE OF GOL SCALE TO MEASURE PERCEIVED EXERTION IN SOCCER

POLITO, L.F.T.1,2, FIGUEIRA JUNIOR, A.J.1, ZANETTI, M.C.1, BOCALINI, D.S.1, MARQUEZI, M.L.3, LINO, J.3, NUNES, H.R.2, PONCIANO, K.1, MONTENEGRO, C.G.P.4, BRANDÃO, M.R.F.1

1:USJT (São Paulo, Brazil), 2:UMESP (São Paulo, Brazil), 3:UNICID (São Paulo, Brazil), 4:HIAE (São Paulo, Brazil)

Introduction The peripheral signals integration from the muscles and joints and also the central signals from ventilation have their integration in the somatosensory cortex, enabling general or local perception of effort. Despite the Rate of Perceived Exertion usually used to estimate the internal training load and monitoring the exercise, few instruments have been developed and validated for specific sports. This study aimed to analyze the preliminary evidences of validation of a scale for soccer players named Gol Scale. **Methods** The new scale has been developed in two phases. In the first phase the cartoons of the scale were drawn based on the theoretical construct of perceived exertion. The final version of the scale is composed by six cartoons that show different grades of effort (1: low effort to 6: exhaustion). To ensure the representativeness of the cartoons they were validated by judges (nine PhD professors: physiologists, sports trainers and sports psychologists). In the second phase 13 soccer players (18.8 ± 0.77 years old, stature 177 ± 8.0 cm, body mass 70.8 ± 7.53 kg, % body fat 13.42 ± 3.19 , lean mass 60.49 ± 4.75 kg and fat mass 9.60 ± 3.19 kg) were evaluated by a 3 minutes progressive protocol up to exhaustion with 1-minute recovery between stages. The Borg Scale 6-20, The Cavasini Scale, The cartoon Gol Scale, Heart Rate (HR), Percentage of Heart Rate (%HR) and Blood Lactate Concentration ([La]) were immediately determined after each stage. Pearson's correlations coefficients were used. The level of significance was .05. **Results** We found significant correlation between the Gol Scale and Borg Scale 6-20 ($r = 0.92$, $p < 0.05$), Cavasini Scale ($r = 0.92$, $p < 0.05$), %HR ($r = 0.88$, $p < 0.05$), HR ($r = 0.82$, $p < 0.05$), and [La] ($r = 0.66$, $p < 0.05$). **Discussion** A recent theoretical model explain that perceived exertion is associated to the increase of corollaries stimuli to motor impulses. The intensification of motor impulses generated by the central nervous system for the movement executions would be the main factor responsible for the increased of the RPE. These results showed that the Gol Scale is a promissory instrument for measuring perceived exertion. References Costa E.C., Vieira C.M.A., Moreira A., Ugrinowitsch C., Castagna C., Aoki M.S. (2013). BIOCHEMICAL AND FUNCTIONAL ANALYSIS OF MUSCLE RESPONSE TO A HIGH INTENSITY CONCENTRIC EXERCISE

ILLERA, V.1, CARMONA, G.1, PADULLÉS, J.M.1, PADULLÉS, X.1, LLORET, M.1, GUERRERO, M.2, CUSSÓ, R.2, CADEFAU, J.A.1,2

1:INEFC-UB (Barcelona, Spain); 2:Dep. Physiol. Sci. I, University of Barcelona (Barcelona, Spain)

Introduction It is generally assumed that concentric muscle actions cannot lead to severe exercise induced muscle damage (EIMD). A higher mechanical strain produced in eccentric actions is one of the main causes of sarcomeric disruptions (Fridén et al., 2001). However, other indirect mechanisms of EIMD are the accumulation of metabolic products and the increased production rate of Reactive Species, produced by a hypermetabolic state (Fisher-Wellman et al., 2009). The aim of this study was to assess the extent of EIMD when concentric muscle actions are performed at very high intensity. **Methods** 9 physically active men (age 24.2 ± 2.9 years) performed 3 sets of the Wingate anaerobic test on a Lode Excalibur Sport cycle ergometer. 4 minutes of active rest were given between sets. Each set consisted of 30 seconds of all-out cycling against a resistance designed to elicit the maximum mechanical power (0.75N/kg body weight). Serum biomarkers of EIMD, including CK, CK-MB, AST, ALT, cardiac troponin I (cTnI), slow myosin (SM) and fast myosin (FM) isoforms were assessed before exercise, and 1 minute, 1, 24, 48 and 144 hours after exercise. Other indirect markers of EIMD as Delayed Onset Muscle Soreness (DOMS), Maximum Voluntary isometric Contraction force (MVC) of knee extensors, Counter Movement Jump height (CMJh), and 8 seconds cycling peak power were also assessed following the same time sequence. **Results** Effort caused a great decrease in muscle function ($-16.1 \pm 13.4\%$ MVC, $p = .007$; $-26.5 \pm 19.7\%$ CMJh, $p = .001$) and high levels of muscle pain (7.7 ± 1.9 in a 0-10 scale) after exercise. MVC and CMJh were re-established 1 hour after exercise and pain diminished near basal values, showing no posterior increments. A significant increase was shown in CK ($+161.3 \pm 48.3\%$, $p = .020$) values 24 hours after exercise, which decreased progressively thereafter. There were no significant changes in concentrations of fast and slow myosin, nor differential behaviour between the two markers. AST, ALT and

cTnI showed no changes during all the follow up. Discussion High intensity concentric muscle actions cause acute muscle fatigue and the release of cytoplasmic enzymes into the bloodstream. Fast recovery of muscle function, disappearance of muscle pain, and absence of changes in sarcomeric markers, suggest an increase in membrane permeability (Brancaccio et al., 2010), with muscle structure not being significantly affected. PERCEIVED EXERTION IS LOWER IN RUNNING THAN WALKING AT THE SAME HEART RATE AND LACTATE LEVEL

SAKAMOTO, M., TANAKA, H.

Fukuoka University

The purpose of this study was to examine physiological characteristics of perceived effort to relative intensity in human walking and running. Fifteen male subjects participated in this study. Two progressive protocols were randomized, starting at a treadmill speed of 3 Mets to measure ratings of perceived exertion (RPE), heart rate (HR) and blood lactate. From these data, RPE was estimated at an intensity corresponding to fixed HR (FHR; 120, 130, 140, 150 bpm) and fixed blood lactate concentrations (FBLC; 2 and 3 mM) from the individual regression line. RPE in running was significantly lower than in walking at FHR of 120, 130, 140 and 150 bpm, respectively ($p<0.01$ for all). For blood lactate, RPE in running were significantly lower than in walking at FBLC of 2 and 3mM, ($p<0.05$, 12.6 ± 1.7 vs 14.0 ± 1.7 and 15.1 ± 1.4 vs 16.9 ± 2.4 respectively). Running may be performed more easily than walking at the same physiological demand. Factors other than blood lactate may affect perception of exertion during walking.

BASKETBALL MATCH-INDUCED DEHYDRATION IS RELATED TO A REDUCED JUMP HEIGHT AFTER A MATCH IN YOUNG BASKETBALL PLAYERS

DÍAZ-CASTRO, F., ASTUDILLO, S., CALLEJA-GONZALEZ, J., PEÑAILILLO, L., ZBINDEN-FONCEA, H., CASTRO-SEPÚLVEDA, M.

Finis Terrae University, Exercise Science Laboratory

Muscle damage and dehydration have separately been shown after basketball matches. However, their influence in jumping performance is unknown. The aim of this study is to relate the jump height to indirect muscle damage markers, lost of fluids, and changes in plasma electrolyte levels in young basketballers after a match. 14 basketballers (17.1 ± 3.4 years) participated in this study. Sodium (Na⁺), potassium (K⁺) and creatine kinase isoenzymes (CK) concentration, urine specific gravity (USG), body mass and countermovement jump height (CMJ) were measured before and after a match. Na⁺ ($p<0.002$), CK ($p<0.0001$) were increased (1.4% and 38.1% respectively) after match, whilst body mass (fluid loss) ($p<0.0001$) and CMJ ($p<0.0002$) decreased (1.3% and 10.8%, respectively). Reduced CMJ performance was associated with increased Na⁺ ($r=0.67$, $p=0.01$), but not with reduced K⁺ ($r=0.36$, $p=0.21$) levels. Reduced CMJ performance was also correlated to fluid loss ($r=0.067$, $p=0.01$), but not with CK increased ($r=0.10$, $p=0.73$). Fluid loss was related to pre-match body mass and USG ($r=0.68$, $p=0.01$; $r=-0.58$, $p=0.02$, respectively). In conclusion a basketball match induces muscular damage and dehydration. However, only dehydration and increases in plasma Na⁺ after match were associated with changes in jump height.

EFFECT OF 12 WEEKS EXERCISE PROGRAM ON CIRCULATING LEVELS OF WNT INHIBITORS IN BREAST CANCER SURVIVORS

YEH, B., KIM, T., CHANG, J., KIM, H., KONG, I.

Yonsei University Wonju College of Medicine

Introduction Dickkopf-1 (DKK1) and secreted frizzled-related protein-1 (SFRP1) are inhibitors of Wnt/β-catenin signaling. Accumulating evidence suggests that higher serum level of DKK1 is positively correlated with pathologic conditions such as cancer and atherosclerosis. Furthermore, DKK1 disrupts osteoblast differentiation and precipitates osteoporosis. Several recent studies showed that exercise reduces DKK1 level in healthy volunteers or experimental animals. We investigated the changes of serum levels of DKK1 and SFRP1, as Wnt/β-catenin inhibitors, by long-term exercise in breast cancer patients. Methods Twenty four breast cancer patients (50.4 ± 11.8 years of age) after chemo- or radiotherapy were participated. Intervention groups were randomized to 12 wks of breast cancer exercise program ($n=11$) or control group ($n=13$). Blood samples were collected to examine the serum level of DKK1 and SFRP1. Results The serum levels of DKK1 ($p < .01$), SFRP1 ($p < .01$) and leptin ($p < .05$) were significantly reduced during 12 wks exercise program. However, those in control group were not changed during 12 wks. Also adiponectin/leptin ratio was significantly reduced during exercise program compared to control group ($p < .05$). The serum level of insulin was significantly decreased during 12wks exercise intervention ($p < .05$), but serum level of Hs-crP was not significant changed. Exercised group showed remarkable increases in health related fitness such as hand-grip strength, muscle endurance, flexibility ($p < .05$). Also, body fat percentage ($p<.01$), waist circumference and visceral fat area were significantly decreased in exercised group compared to control group ($p < .05$). Conclusion Our results suggest that long-term exercise decreases serum levels of DKK1 and SFRP1, which may contribute to the beneficial effects of exercise on physical fitness and metabolism in cancer patients. DKK1 and SFRP1 could be a therapeutic target for prevention of disease complications and improvement of metabolism. Contact Byung Il Yeh, MD, PhD: mia1@yonsei.ac.kr

GENDER DIFFERENCES IN SALIVARY HORMONES AND PERCEPTION OF EXERTION OF ELITE VOLLEYBALL PLAYERS DURING TOURNAMENT

PEÑAILILLO, L., ESCANILLA, F., JURY, E., CASTRO-SEPULVEDA, M., ZBINDEN-FONCEA, H.

Universidad Finis Terrae

Do not insert authors here! Sports tournaments induce both physiological and psychosocial stress, which seems to be different between men and women [1]. It induces anticipatory rises in testosterone and cortisol hormones, which may affect performance and perceived exertion. The aim of this study was to compare the changes in salivary cortisol and testosterone concentrations between men and women during an official volleyball tournament and to correlate the changes in these hormones with the perceived exertion after match. Methods Three matches of each team were assessed in the group stage of the Men and Women South American Volleyball Championship. Measures of salivary cortisol and testosterone were taken in fasting state, before and after each match [2]. The rate of perceived exertion (RPE) was assessed after each match. Changes in these variables were compared between men and women and

between matches with a multifactorial ANOVA. Results Fasting cortisol concentrations were higher in women than men and fasting testosterone was higher in men than women. Women did not increase their cortisol concentrations after any match. However, cortisol concentration increased after the second match. The average rate of perceived exertion was correlated with the average change in testosterone level after the matches in both women and men, which was not observed for cortisol concentration. Discussion These results suggest that women have more pronounced anticipatory responses and increase their hormonal levels less throughout tournaments than men. It seems that hormone changes in men are modulated by the experience in this type of competition and the opponent's level. References 1) Kivlighan et al. 2005. THE RELATIONSHIP BETWEEN BALANCE, ENDURANCE OF CORE MUSCLES AND ANAEROBIC PERFORMANCE IN PROFESSIONAL BASKETBALL PLAYERS

AKSEN CENGIZHAN, P.1, ZORLULAR, A.2, COBANOGLU, G.2, GOKDOGAN, C.2, AKARAS, E.2, ERIKOGLU ORER, G.3, ERIKOGLU, O.4, KAFA, N.2, ATALAY GUZEL, N.2

1:KUFSS (Kırıkkale,Turkey), 2:GUFHS (Ankara,Turkey), 3:YBUFHS (Ankara,Turkey), 4:TEDC (Ankara/Turkey)

Introduction The purpose of this study was to identify relationships between endurance of core muscle, balance and anaerobic performance in basketball players. The muscles of the core help control movements, transfer energy, shift body weight and distribute the stresses of weight-bearing. Balance is the ability to maintain the Center of Gravity (COG) of a body within the base of support with minimal postural sway. Functional movements are highly dependent on the core endurance, and lack of core muscles strength can result in decreased performance and balance. Methods 20 professional male basketball players (age 17 ± 0.64 , height 186.1 ± 6.7 , weight 78.9 ± 9.38) were included to this study. Balance was measured using Biodes Biosway™. Endurance of core muscle was evaluated using McGill Core Endurance Tests. Anaerobic performance was assessed with running based anaerobic sprint test (RAST). Statistical analysis was performed using the statistical software SPSS. Results Spearman correlation analysis results showed that there was positive significant correlation between performance and endurance of core muscles ($p < 0.05$). A positive significant relationship was demonstrated between anaerobic performance and balance ($p < 0.05$) and between balance and endurance of core muscles ($p < 0.05$). Discussion In this study, it was shown that there were statistically significant relationship between core endurance, balance and anaerobic power which effects the athletes performance directly during the match. Therefore, it can be suggested core muscle endurance exercises should be integrated to normal sports specific training programmes in basketball players. References Guskiewicz K. THERAPEUTIC PERCUTANEOUS ELECTROLYSIS COMBINED WITH ISOINERTIAL ECCENTRIC EXERCISE FOR THE MANAGEMENT OF CHRONIC PATELLAR TENDINOPATHY: A 3 MONTH FOLLOW-UP STUDY

FERNÁNDEZ, Á., TRUYOLS, S., FERNÁNDEZ, T.

Camilo Jose Cela University

Introduction Galvanoxtasis reactions modulated by percutaneous electrolysis seems to be a promising new therapeutic approach for chronic tendinopathy. There is evidence that eccentric exercise programs elicits therapeutic benefits for this pain condition. The purpose of the present study is therefore to ascertain the effectiveness of using EPTE® combined with isoinertial eccentric exercise (IEE), as compared to using EPTE® solely as treatment for chronic patellar tendinopathy. Methods 17 patients (6 women and 11 men; age 33.41 ± 11.82) diagnosed clinically and confirmed by ultrasonography with unilateral insertional chronic patellar tendinopathy of at least 3 months length were randomized in two groups; 8 assigned to receive EPTE® intratendinous guided by ultrasonography with a needle of 0.32 mm to $350 \mu\text{A}/\text{cm}^2$ for 1 minute and 20 seconds at the to the lower pole of the patella, for 5 sessions once a week. The other 9 patients were assigned to receive the same EPTE® treatment plus an evidenced IEE protocol (Romero-Rodriguez, 2011). Pain, function and ability to undertake physical activity was measured with VAS (0-10) scale and VISA-P questionnaire, respectively, same as ultrasonographic measurement of the tendon thickness, greyscale imaging and Doppler flow was performed on first and last treatment session, and at 3 month follow-up. Results & Discussion Initially, there were no significant differences between the groups at any outcome. In both groups there were a significant improvement in the total score of the VISA-P questionnaire (Both groups at baseline: 56.71 ± 13.23) being greater at IEE group after the last treatment session (76.25 ± 13.29 EPTE® only vs. 87.11 ± 5.97 IEE; $P=0.043$) and at 3 month follow-up (83.63 ± 11.44 vs. 92.11 ± 4.88 ; $P<0.01$). IEE group showed more capabilities to retake, pain free, physical activity, likely due to the well known tendon structural changes associated with eccentric loads as literature reports. Pain was improved in both groups (Both groups baseline: 7.12 ± 1.58 , last treatment session: 3.12 ± 1.58 ; $P<0.001$, 3 month follow-up: 1.71 ± 1.05 ; $P<0.001$), without significant differences between groups at any time ($P>0.05$). The ultrasonographic thickness significantly decreased in both groups at 3 months (Both groups baseline: 0.74 ± 0.10 cm, 3 month follow-up 0.71 ± 0.11 cm; $P<0.05$), same as disappearance of the hypoechoic areas in 10 of the 17 tendons, without significant differences between groups ($P>0.05$). Neovascularity trail was present at 7 of 17 tendons, disappearing after treatment completion in both groups ($P<0.001$), possibly as result of tendon regenerative process going on (Malliaras, 2010). Our findings suggest that treatment with EPTE® combined with an isoinertial eccentric training shows good and safe clinical results in patients with chronic patellar tendinopathy, specially those patients who are willing to retake physical activity soon. LEG DOMINANCE AND BONE CROSS-SECTIONAL GEOMETRY OF THE PROXIMAL FEMUR IN ELITE CRICKET FAST BOWLERS

HIND, K., BANSIL, K., LEES, M.

Leeds Beckett University

Introduction: The skeleton of an elite cricket fast bowler is exposed to substantial ground reaction forces that are delivered through the front foot during the contact phase. There is also significant loading to the lumbo-pelvic region, through peak transverse plane rotation moments and increased anterior posterior shear forces. Non-contact bone injuries are common amongst elite cricket fast bowlers, but few studies have investigated unilateral bone strength in this sports population. The aim of this study was to investigate bone cross-sectional geometry of the proximal femur in elite fast bowlers to determine if any asymmetries or insufficiencies exist. **Methods:** Dual energy X-ray absorptiometry (GE Lunar iDXA) of the left and right proximal femur was performed in 16 elite male fast bowlers (age: 21.4 ± 4.4 years; BMI: 24.7 (2.2) kg.m⁻²; %body fat: 18.0 (3.8); lean tissue mass (LTM): 66.7 (5.3) kg) and 12 normally-active controls (age: 21.4 (1.6) years; BMI: 23.7 (2.6) kg.m⁻²; %body fat: 20.5 (5.0); LTM: 56.5 (3.8) kg). The hip structural analysis programme (enCORE v 15.0) determined areal bone mineral density (BMD), cross-sectional area (CSA), section modulus (Z), and cross-sectional moment of inertia (CSMI) and bone strength index (BSI) of the femoral neck. **Results:** Femoral neck, wards area, trochanter and total hip aBMD were significantly greater in fast bowlers than controls, and differences remained after adjustment for LTM (1.202 to 1.417 g.cm⁻² v 0.982 to 1.163 g.cm⁻², p<0.005). All bone geometrical properties of the left and right femur were superior in fast bowlers compared to controls (p=0.024 to p<0.001), and after adjustment for LTM, differences in CSA and BSI remained (p<0.01). There were no associations with age. There were no asymmetries in bone density or geometrical properties when considering leg dominance (front foot) of the fast bowlers (p=0.103 to 0.784). **Conclusions:** This study indicates that elite male fast bowlers have superior bone strength of the proximal femur with results inferring an enhanced resistance to axial (CSA), bending (Z) and compressive loads (BSI). This is likely to reflect a positive adaptation of bone to loading through fast bowling and greater LTM. No asymmetries in femur bone properties were identified.

MUSCLE STRENGTH CHARACTERISTICS OF ANKLE AND TOE IN RUNNERS WITH HISTORY OF MEDIAL TIBIAL STRESS SYNDROME

SAEKI, J., NAKAMURA, M., NAKAO, S., SYOJI, M., FUJITA, K., YANASE, K., ICHIHASHI, N.

Kyoto University

Introduction: Medial tibial stress syndrome (MTSS) is one of the most common overuse injuries in runners. Because of pain location and alignment during running, MTSS is considered to associate with elongational stress to inverter muscles. However, studies on muscles strength in athletes with MTSS revealed conflicting results. Because flexor digitorum longus (FDL) and flexor hallucis longus (FHL) works as the inverter of the ankle, strengths of hallux and lesser toe could relate to MTSS. However, muscle strength of the hallux and lesser toes has conventionally not been evaluated because of the lack of method to evaluate this strength quantitatively. In this study, using a newly developed device, we examined the muscle strength characteristics including the 1st metatarsopharangeal joint (MTPJ) and 2nd to 5th MTPJ in runners with MTSS history. **Methods:** Eighteen collegiate male runners (10 subjects with bilateral MTSS history, 1 with unilateral MTSS, and 7 without MTSS history) participated in this study. Their limb were classified into either MTSS group (history limbs, 21 limbs) or no history group (no history limbs, 15 limbs). MTSS history was defined as those who meet the following criteria; 1) having an experience of exercise induced pain which is located on the posteromedial border of the tibia, 2) palpation of the posteromedial border of the tibia produced discomfort, 3) the site had to be spread over a minimum of 5 cm, 4) no diagnose of stress fracture by surgeon, 5) no pain in lower limb now. We measured maximal voluntary isometric contraction (MVIC) torque of plantarflexion, dorsiflexion, inversion and eversion of ankle using an electrical dynamometer. Additionally, MVIC torque of the 1st MTPJ and 2nd to 5th MTPJ were measured using a custom made torque measuring device (Saeki et al., 2015). Unpaired t-test was used to test the difference of each MVIC torques between the two groups. Results MTSS history group produced significant higher MVIC torque of 1st MTPJ than no history group. There was no difference between two groups in other indices. Discussion Elongational stress to the tibialis posterior (TP), FDL or soleus is considered to be one of the causes of MTSS (Moen et al., 2009). MTSS history limbs produced higher MVIC torque of 1st MTPJ than no history limbs in this study. This result suggested that activity of the FHL, which originate not from the tibia but has the same function of inversion may increase to reduce the load on TP or FDL during running in MTSS history limb. IMPACT OF THREE-POINT WALKING IN WOMEN WITH TOE DEFORMITY

NOGAMI, Y., OHARA, K.

Shonan Institute of Technology

Introduction: Toe deformity as hallux valgus (HV) and floating toes, is the common foot pathologies problem in modern society. Previous study was reported that patients with HV were larger in women compared to men, because the majority women wear high heels and thin shoes. Normally, healthy foot has three arches. There are anterior transverse arch, lateral longitudinal arch, and medial longitudinal arch. However, if there is a toe deformity, these three arches of the foot collapses. Additionally, these collapses cause lumbar pain, stiff shoulder, autonomic imbalance and so on. Three-point walking could replace to the healthy foot. Therefore, the purpose of this study was to evaluate whether three-point walking improved toe deformity in women. **Methods:** Seven healthy women were enrolled in this study. All subjects underwent a three-point walking. And wear the sock, as a roll of taping with three arches. They walked to continue 3 months, twice a week, 30 minutes per each time. We measured muscle hardness in lower back, toe muscle power, plantar pressure, bearing area of the plantar, and position of the center of gravity. Additionally, we evaluated toe condition score, as a quantitative parameter. Results Mean subjects age was 42 ± 6 years. Muscle hardness in lower back was not significantly changed in 3 months walking. However, toe muscle power after walking was significantly increased compared to before walking (right, 16.7 ± 2.7 vs. 19.6 ± 3.0 kg, P = 0.04; left, 16.2 ± 2.7 vs. 19.1 ± 3.7 kg, P = 0.03). Appearance ratio with HV in 3 months after walking was significantly decreased compared to before walking (42.9 vs. 7.1 %, P = 0.05). Floating toe score and bearing area of the plantar were significantly improved with walking (floating score, 5.9 ± 3.1 vs. 13.1 ± 4.1, P = 0.01; bearing are, 40.1 ± 15.6 vs. 56.3 ± 12.1 %, P = 0.01). In addition, position of gravity was shown a trend toward improvement in 3 months after walking (3.4 ± 1.9 vs. 4.6 ± 0.7, P = 0.08). **Discussion:** Three-point walking increased toe muscle power. Moreover, appearance ratios with HV, floating toe score, and bearing area of the plantar were significantly

improved with walking. Consequently, three-point walking in 3 months improved toe deformity in women. References Morales-Orcajo E, Bayod J, Becerro-de-Bengoa-Vallejo R, et al. (2015). Med Biol Eng Comput, 53(7), 645-653.

NON-ELITE ATHLETES WITH VENTRICULAR PREMATURE BEATS: WHAT IS THE ARRHYTHMIC BURDEN CONTINUING INTENSE TRAINING?

TRANCHITA, E., PARISI, A., MINGANTI, C., SPERANDII, F., GUERRA, E., CALÒ, L., BORRIONE, P., PIGOZZI, F.

UNIVERSITY OF ROME - FORO ITALICO

INTRODUCTION Isolated ventricular premature beats (VPBs) are commonly found during pre-participation screening in athletes. Several studies on elite athletes suggest that VPBs may be expression of 'athletes' heart', other authors advise that VPBs may increase the cardiovascular risk and rise suspicion of Cardiomyopathy. Currently the debate about the role of detraining in reducing the number of VPBs is still open (Biffi et Al, 2002; Mc Claskey et Al, 2013). The aim of the study was to evaluate the arrhythmic burden and follow-up in a population of young competitive non elite athletes showing VPBs during pre-participation screening and that continued practicing competitive sports. **METHODS** In a four-year period, 2784 subjects underwent to pre-participation screening. Athletes who showed VPBs were selected (n.66) and underwent to a complete second level evaluation (Echocardiogram, 24h Holter Electrocardiogram (ECG) recording and Maximal Exercise test). Athletes were re-evaluated after 6 to 48 months, while they continued practicing competitive sports. **RESULTS** 2,3% of total screened population showed ventricular arrhythmias. Among this athletes 80% showed isolated VPBs. 83% showed monomorphic VPBs, 17% showed polymorphic VPBs. There was not relation between morphology of VPBs and gender, number of VPBs/24h or complexity of VPBs. At echocardiogram no pathology determining exclusion from competitive activity was found. No athlete showed exercise-induced VPBs. At Holter ECG recording mean number of daily VPBs was 1777 ± 4045 (range 0-23.094). Exercise test follow-up (17 ± 12 months) did not show any worsening in the pattern of presentation of VPBs and the complexity of arrhythmias was unchanged. At Holter ECG follow-up (21 ± 13 months) the median number of VPBs decreased from 309 (IQR 20-3065) to 149 (IQR 2-1299); the complexity of VPBs was reduced. **DISCUSSION** Continuing competitive sport in athletes with ventricular arrhythmias even frequent, with a low grade of complexity and without structural cardiomyopathy at echocardiogram, did not increase the arrhythmic burden. **REFERENCES** Biffi A, Pelliccia A, Verdile L et Al. IMMEDIATE CHANGES IN MEDIAL ELBOW LAXITY DURING REPETITIVE THROWING IN HIGH SCHOOL BASEBALL PLAYERS

HATTORI, H.1,2, AKASAKA, K.1,3, OTSUDO, T.1,3, SAWADA, Y.3, TAKEI, K.2, YAMAMOTO, M.2

1: Saitama Medical University Graduate School of Medicine, 2: Saitama Medical Center, Saitama Medical University, 3: School of Physical Therapy, Saitama Medical University

Introduction Although a previous study has demonstrated changes in medial elbow laxity over time in baseball pitchers (Ciccotti MG, 2014), the immediate effects of baseball pitching on elbow laxity has not been reported. Therefore, the purpose of our study was to investigate the immediate changes in medial elbow laxity following repetitive throwing. **Methods** 19 high school baseball players participated in this study. Each subject pitched 100 times. Ultrasound imaging of the medial aspect of the elbow was obtained under two conditions: 1. gravitational stress applied at 90 degree elbow flexion and 2. 30 N of valgus stress on the ulnar styloid process at 30 degree elbow flexion. In each situation the subject was supine with the shoulder in 90 degrees abduction. Measurement of laxity was carried out before pitching and after every 20 pitches. 2-way repeated measures ANOVA was used to compare ulnohumeral joint space width between repeated trials, and between gravity stress and 30N of valgus stress. This study was approved by the Ethics Committee at the Saitama Medical University, Saitama, Japan (M-66). Results Ulnohumeral joint space width (mean \pm SD: under gravity stress and 30N of valgus stress) was as follows: prior to pitching (4.98 ± 0.96 mm, 5.59 ± 0.89 mm), after 20 pitches (5.23 ± 0.97 mm, 6.04 ± 0.77 mm), after 40 pitches (5.55 ± 0.88 mm, 6.30 ± 0.80 mm), after 60 pitches (5.88 ± 0.96 mm, 6.55 ± 0.79 mm), after 80 pitches (6.01 ± 1.12 mm, 6.88 ± 1.01 mm) and after 100 pitches (6.24 ± 1.08 mm, 7.24 ± 0.99 mm). 2-way repeated measure of ANOVA showed significant differences between ulnohumeral joint space width before pitching and following every 20 pitching, and between gravity stress and 30N of valgus stress. Post hoc testing showed that after more than 60 pitches, ulnohumeral joint space width was significantly greater than prior to pitching ($p<0.05$). In addition, there were also significant changes in ulnohumeral joint space width with gravity stress and with 30N of valgus stress. **Discussion** In our study, it was likely that repetitive loading of elbow valgus stress during repetitive throwing contributed to the increase in medial elbow laxity. Although previous studies have assessed medial elbow laxity using gravity stress or Telos stress (Harada, M, 2014), our study is the first to assess gravity stress and 30N of valgus stress, and the results were consistent with previous studies. **References** Ciccotti MG, et al. DYNAMIC KNEE VALGUS INFLUENCES ANGULAR IMPLUSES IN THE LOWER EXTREMITY DURING THE DECELERATION PHASE OF A SINGLE-LEG LANDING

TAMURA, A.1,2, AKASAKA, K.1,3, OTSUDO, T.1,3, SAWADA, Y.3, OKUBO, Y.1,3, SHIOZAWA, J.4, TODA, Y.5, YAMADA, K.6

Saitama Medical University Graduate School

1: Saitama Medical University Graduate School of Medicine, 2: Sekishindo Hospital, 3: Saitama Medical University, 4: Zenshukai Hospital, 5: Yokohama Asahi Center General Hospital, 6: Kanetsu Hospital **Introduction:** Dynamic knee valgus during landings has been associated with an increased risk of non-contact ACL injuries. Additionally, the shock imposed on the body during landings must be attenuated by "soft" landings in the lower extremity. It has been suggested that decreasing the capacity to attenuate the shock is one of the factors to cause a knee injuries including ACL. The purpose of this study was to investigate the characteristic of the shock attenuation mechanism on dynamic knee valgus by measuring the vertical ground reaction impulse (vGRI) and angular impulses in the lower extremity during the deceleration phase of a single-leg landing. **Methods:** Thirty-four college females participated in this experiment. They performed the single-leg drop vertical jump. Lower extremity kinetics and kinematics data were obtained from the 3D motion analysis system and two force plates. All participants were divided into the valgus group (N=19) and the varus group (N=15) according to knee angular displacement in the frontal plane during the deceleration phase, defined as the time period from initial contact to peak vertical ground reaction force (vGRF). The vGRI and angular impulses of hip, knee and ankle were calculated by integrating the vGRF - time and the respective joint

moment - time curves. Unpaired t test was used to analysis the difference between two groups. This study was approved by the Ethics Committee at the Saitama Medical University, Saitama, Japan (M-54). Results: The vGRI was no difference between two groups ($p>.05$). Knee angular impulse in the valgus group was significantly greater than those in the varus group (0.91 ± 0.31 vs. 0.44 ± 0.40 Nms/kgm, $p<.01$). On the other hand, hip angular impulse in the valgus group was significantly smaller than those in the varus group (0.18 ± 0.33 vs. 0.65 ± 0.29 Nms/kgm, $p<.01$). There was no difference in ankle angular impulse between two groups ($p>.05$). Conclusion: The vGRI and angular impulses show the net force and joint moments applied to the lower extremity over time periods during the deceleration phase of landings. From this study, our results indicated that dynamic knee valgus cause a increasing of the shock applied to knee joint. In addition, dynamic knee valgus might attenuate the shock in hip joint during the deceleration phase of landings. These findings suggest the importance of evaluations and exercises related to the shock attenuation mechanism on dynamic knee valgus. Contact: a.tamura.dp@gmail.com

VIDEO ANALYSIS OF HEAD INJURIES CAUSED BY TACKLING IN COLLEGE RUGBY UNION PLAYERS

KEITA, S., MASAHIRO, T., SATOSHI, N., TAKUO, F., KOICHI, I., SHUMPEI, M.

University of Tsukuba, Ibaraki Prefectural University of health science, Tsukuba International University

Introduction In recent years, we focus on head injuries included concussion to have possibilities to trigger catastrophe in rugby union. Head injuries and concussion alike were commonly sustained in the tackling (Kemp et al., 2008). Thus, it suggests that we need to analyze injury situations during tackling in particular. Additionally, to make a comparison between injury situations and general tackle situations, we clear up the questionable points to head injuries caused by tackling. Therefore, the aim of this study was to identify mechanisms of head injuries caused in rugby union from video records. Methods Elite collegiate rugby players sustained head injuries in match were extracted during six playing seasons in Japan collegiate rugby union. Tackle which caused a head injury and general tackle in the same match which tackles were performed by the injured tacklers before the head injury happened were coded risk factors for head injuries from video records of the matches (Fuller et al., 2010; Quarrie et al., 2008). Risk factors for head injuries were determined using a logistic regression model. Results 56 players sustained head injuries during the six seasons. 42 head injuries of all head injuries during the six seasons were coded risk factors from video records and 22 head injuries were caused by tackling. The following performance were extracted for head injuries : tacklers approached and contacted ball carriers, with moving same direction of the ball carrier (OR, 21.6; 95%CI, 6.3-73.8; $p=0.00$), head or neck of tacklers contacted ball carriers (OR, 7.8; 95%CI, 1.3-47.0; $p=0.03$), tacklers hit from front side of ball carriers (OR, 32.8; 95%CI, 1.9-559.12; $p=0.02$) Discussion Head injury were more frequency caused by tackling. We found that moving same direction of the opposition player before the tackle situation, contacting by head and static condition in the tackle situation were associated with head injuries. Concussion occurred when linear and/or rotational force are transmitted to the brain (Harmon et al., 2013). Thus, enough damage to the brain may result from contacting the opposition player by the head of the tackler. References Fuller CW, Ashton T, Brooks JH, Canea RJ, Hall J, Kemp SP. (2010). THE RELATIONSHIP BETWEEN THROWING VELOCITY AND SHOULDER INTERNAL AND EXTERNAL STRENGTHS IN JAPANESE WATER POLO PLAYERS AGED 9 – 18 YEARS

KOMORI, Y., KITADA, K., SEGAWA, E., SHIMURA, Y.

Osaka International University

Introduction Throwing is one of the most important skills in water polo. Throwing factors are difficult to determine for various reasons such as differences in physical fitness and techniques. The relationship between throwing velocity and shoulder internal and external muscle strengths in baseball players has been studied extensively (Cater, et al., 2007). Compared with that in baseball, the throwing movement in water polo differs according to the size of the ball. Therefore, this study aimed to examine the relationship between throwing velocity and shoulder internal and external muscle strengths in different age water polo players. Methods A total of 48 Japanese water polo players participated in this study. The participants were divided into the following 3 groups according to age range: elementary school group ($n = 16$; ages, 9 - 12 years), junior high school group ($n = 13$; ages, 13 - 15 years), and high school group ($n = 19$; ages, 16 - 18 years). During a penalty throw, each player threw the ball 3 times to shoot at the goal. The throwing initial velocity was measured by a speed gun using Doppler ultrasonography. The following physical fitness indicators of the shoulder joint were used: internal and external isometric muscle strengths were measured using a handheld dynamometer (μ Tas F-1, Animal). Results The throwing initial velocity was 43.2 ± 8.7 km/h, 55.9 ± 4.9 km/h, and 60.0 ± 5.7 km/h, in the elementary school, junior high school, and high school groups, respectively. The internal and external isometric muscle strengths were increase with advancing age. Moreover, the internal and external isometric muscle strengths on the throwing side were higher than those on the non-throwing side. The throwing initial velocity had a moderate correlation with internal and external isometric muscle strength on the throwing side. Conclusions These findings showed a correlation between throwing velocity and internal and external muscle strengths regardless of age. Therefore, increased shoulder internal and external muscle strengths are required. In conclusion, the results of this study suggested that the shoulder internal and external isometric muscle strengths were important indicators of throwing velocity in water polo players. TRAINING LOAD AND SUBSEQUENT WELLNESS UNDERTAKEN BY AN ELITE SOCCER GOALKEEPER: A CASE STUDY REPORT

MALONE, J.1, JASPERS, A.2, HELSEN, W.2, FRENCKEN, W.G.P.3,4, BRINK, M.S.3,4

1: Catapult Sports (UK), 2: University of Leuven (Belgium), 3: University of Groningen (Netherlands), 4: Hanze University of Applied Sciences (Netherlands)

Introduction The role of a goalkeeper is a unique but often overlooked position in soccer. Whilst the training load practices of outfield players has been examined in detail (Malone et al. 2015), such information in goalkeepers is relatively unknown. Therefore, the purpose of the present study was to quantify the training load undertaken by an elite professional goalkeeper. **Methods** One male international elite goalkeeper participated in this study. Training load data was collected over an 8 week period during the in-season phase (two mesocycles) using a global positioning system (GPS) device, heart rate and session rating of perceived exertion (S-RPE). The following parameters were exported and analysed from the software: duration, total distance covered, average speed (total distance/total duration), high speed distance ($> 5.5 \text{ m/s}$), high acceleration and deceleration efforts ($> 3 \text{ m/s}^2$), PlayerLoadTM and average heart rate. Data was assessed in relation to the number of days prior to a match (MD-). In addition, the subsequent total wellness was assessed using an adapted questionnaire from Hooper et al. (1995). Results Duration, total distance, PlayerLoadTM and session-RPE were highest on MD-2, but remained similar across the remaining training days. Total wellness scores were highest on MD-3 (mean 21 aul), but remained similar across the training microcycles (mean 17-18 aul). There was no significant relationship between training load measures and the subsequent wellness response across all MD- days ($P > 0.05$). **Discussion** This exploratory case-study provides novel data about the training load undertaken by a goalkeeper towards matches. The data suggest there is a limited relationship between training load measures and subsequent wellness in goalkeepers. Previous work has found large correlations between such measures (Buchheit et al. 2013) using parameters applicable to the athlete's role (e.g. high speed distance covered in Australian Rules Football). The lack of relationship in the present study may be due to the lack of position-specific training load parameters we can currently measure in the applied context. Future work should look to utilise current wearable technology to generate goalkeeper-specific parameters in order to fully understand the loading profile at the elite level. **References** Buchheit et al. THE EFFECTS OF ISOKINETIC HIP FLEXION AND EXTENSION TRAINING FOR MEN'S UNIVERSITY FOOTBALL PLAYERS

MIYAGI, O., KUMAGAI, T.

Daito Bunka university

Introduction The studies about hip muscular strength have been reported that the muscles iliopsoas was active during the entire kicking motion and the mean ball velocity related significantly with hip flexion strength of the kicking leg and hip extension strength of the supporting leg. So this study was designed to clarify the effect of isokinetic hip flexion and extension training over eight weeks training and to examine the change in mean ball velocity by kick, jump height, and sprint speed before and after training for men's football players. **Methods** The Subject were sixteen university football players. The team had trained 12 to 15 practice hours per week and played at least one soccer game per week. There were divided into 2 groups (training group, control group), and measured isokinetic hip Flex/Ext strength at 3 angular velocities (60, 180, 300deg/sec), mean ball velocity by kick, jump height (Squat jump: SJ, Counter movement jump: CMJ), and 30m sprint speed before and after training. Training group did isokinetic hip flexion and extension training. BIODEX SYSTEM 3 was used for training and measurement of muscular strength. Training intensity was 180deg/sec of angular velocity. Training was conducted 3 days per week, 3 sets per day, and 10 repetitions per set for 8 weeks. **Results** As a result, the changes of isokinetic hip Flex/Ext strength were indicated as follows. Isokinetic hip extension strength at 180, 300 deg/sec was significantly improved with training. And isokinetic hip Flex/Ext strength at all angular velocities tended to improve. Mean ball velocity by kick and jump height was significantly improved. Although sprint speed shows no improvement, it tended to improve within after 15m. **Discussion** It suggested that improvement of hip extension strength affected improvement of mean ball velocity and jump height. These results suggested that hip extension strength is important for mean ball velocity and jump height. **References** 1. Dorge,H.C. et al. (1999). Scand. J. Med. Sci. Sports, 9, 195-200. 2. COMPARISON OF DIFFERENT EVALUATION METHODS OF PROFESSIONAL SOCCER PLAYERS' PHYSICAL AND PHYSIOLOGICAL CHARACTERISTICS

BIZATI, Ö.

Ankara University

Introduction The aim of this study is determination of the most suitable and fastest method to measure the physical and physiological capacities of soccer players by comparing laboratory and field tests with software supported non-invasive method (SSNM) relatively new approach. **Method** First of all all players were joined the antropometric measurements (height, weight, fat), SSNM measurements and VO_{2max} measurements. Secondly, lactic acid tests were applied. Thirdly, Aerobic capacity (Yo-yo IR1) test was completed. And finally, anaerobic capacity (Sprint, Sprint Fatigue-Power Maintenance) test were completed. Repeated measures of ANOVA was used to analysis of variable within the triple groups to learn the statistical differences. Paired-Samples t test was used to investigate the differences between binary groups measurements, and coorelation was used to investigation of relationships. **Results** As a result of the measurements, 2mmol HR values and Aerobic threshold maintenance values obtained from the SSNM measurements, 4mmol HR values and Yo-yo IR1 HR values, VO_{2max} HR values and Yo-yo IR1 HR values, VO_{2max} HR values and 4mmol HR values, 4mmol threshold running speed values and Yo-yo IR1 running speed values, SSNM VO_{2max} values and VO_{2max} values, SSNM VO_{2max} values and Yo-yo IR1 VO_{2max} values were similar. But there were differences between SSNM anaerobic threshold HR values and 4mmol HR values, VO_{2max} HR values and Yo-yo IR1 HR values, SSNM anaerobic threshold running speed values and 4mmol threshold running speed values, SSNM anaerobic threshold running speed values and Yo-yo IR1 running speed values. **Discussion** Subjects' running speeds aware determined as $15.42 \pm 0.99 \text{ km/h}$ for 4 mmol level, and $13.65 \pm 0.93 \text{ km/h}$ for SSNM. There are similar resulted studies in literature, 4 mmol running speed is $15.9 \pm 0.9 \text{ km/s}$ (Kunduracioglu et al, 2007), $15.9 \pm 2.6 \text{ km h}^{-1}$ (Berthoin et al., 1994). Subjects' Direct VO₂ max value was determined as $53.53 \pm 2.69 \text{ ml/min/kg}$ and SSNM VO₂ max value was determined as $53.74 \pm 3.90 \text{ ml/min/kg}$. Luhtanen et al., (2007) explained the VO₂ max of soccer palyers is 53.5 ml/min/kg to investigate the heart rate variability at a tournaments. Rampinini et al (2005) was determined VO₂ max of players as $53.3 \pm 4.2 \text{ ml/min/kg}$ at training to determine the physiological load from HR. There is similarity between this study's VO₂ max values and studies of Luhtanen et al., (2007) and Rampinini et al (2005). **References:** Kunduracioglu, B. et al. (2007).

LACTATE TURN POINTS IN INCREMENTAL LEG CYCLE ERGOMETER AND BICEPS CURL EXERCISE

MÜLLER, A., SPENDIER, F., KORINEK, M., GRÖSCHL, W., TSCHAKERT, G., HOFMANN, P.

University of Graz

Introduction The lactate shuttle theory (LST) describes a 3-phase response of the balance between muscle lactate (La) production and local or systemic La oxidation (l). 2 turn points (TPs) separate these phases in incremental ergometer exercise (IET) (l), also described for leg resistance exercise (3). Aim of the study was to determine lactate TPs and to analyse metabolic and cardiorespiratory responses to incremental biceps curl (B) and cycle ergometer exercise (C). Methods 12 trained male (10) and female (2) subjects (24.5 ± 3.2 yrs, 75.2 ± 7.4 kg) performed a cycle IET (20-40W; 15-20W; 1min) to determine the first (LTP1) and the second (LTP2) lactate TP and an IET biceps curl test (B) after a 1RM test. In B, workload was increased by 30% of 1RM/15 kg per min (30 curls/min) up to max. LTP1 and LTP2 were determined by lin. regression break point analysis. Heart rate (HR) and gas exchange variables were measured continuously and La was determined after each load step. Results Pmax in C was 289.6 ± 38.8 W (HRmax: 183.2 ± 10.9 b.min $^{-1}$, Lamax: 11.5 ± 2.3 mmol.l $^{-1}$, VO2max: 3.9 ± 0.5 l.min $^{-1}$). LTP1 was detected at 91.2 ± 21 W (HR: 118.9 ± 12.7 b.min $^{-1}$, La: 1.2 ± 0.4 mmol.l $^{-1}$) and LTP2 at 193.9 ± 27.1 W (HR: 158.8 ± 10.2 b.min $^{-1}$, La: 3.6 ± 0.8 mmol.l $^{-1}$). Peak load in B was 5.1 ± 0.7 kg and HRmax (132.4 ± 14.1 b.min $^{-1}$), Lamax (2.2 ± 0.4 mmol.l $^{-1}$) and VO2max (1.2 ± 0.3 l.min $^{-1}$) were sign. lower. LTP1 was detected at 1.8 ± 0.6 kg (HR: 90.9 ± 13.5 b.min $^{-1}$, La: 0.9 ± 0.4 mmol.l $^{-1}$) and LTP2 at 3.7 ± 0.6 kg (HR: 104.4 ± 10.3 b.min $^{-1}$, La: 1.4 ± 0.4 mmol.l $^{-1}$). %Pmax at LTP1 and LTP2 were significantly different between C (LTP1: La 10.6%; HR 64.9%; LTP2: La 31.5%; HR 86.7%) and B (LTP1: La 41.1%; HR 68.7%; LTP2: La 63.5%; HR 78.9%) but not sign. for power output related to max in B and C (C: LTP1: P 31.5%; LTP2: P 67.0%; B: LTP1: P 34.8%; LTP2: P 71.8%). Discussion LTP1 and LTP2 could be determined in B, and PLTP1 and PLTP2 as well as % of Pmax were comparable between B and C. Values for La and HR at max and LTP1 / LTP2 were sign. different in absolute terms and as % of max between B and C. HR in local small muscle IET such as B shows a different HR pattern due to a different haemodynamic regulation but the 3-phase response as well as the distribution of metabolic phases is comparable to C. These results indicate that the LST may be applied to small muscle group strength endurance exercise. References (1) Hofmann, P. & Tschakert, G. (2011). ASSOCIATIONS BETWEEN DYNAMIC KNEE VALGUS, AND ABDOMINAL AND HIP ABDUCTOR MUSCLES ACTIVATION DURING SINGLE-LEG SQUATS

TAKUYA, A.1, KAGAYA, Y.2, NAKAJIMA, S.3, IMAOKA, M.4

1: Showa University Fujigaoka Rehabilitation Hospital (Yokohama, Japan), 2: School of Nursing and Rehabilitation, Showa University, 3: Koto Toyosu Hospital, 4: Harajuku Rehabilitation Hospital

Introduction Many researchers conduct the screening test for dynamic knee valgus to prevent non-contact anterior cruciate ligament injury. The factors of dynamic knee valgus are detailed malalignment of lower extremity caused by dysfunction of abdominal or hip abductor muscles. The activities of thigh muscles during single-leg squats were indicated, but there were few reports about abdominal and hip abductor muscles. The aim of this study was to determine association between dynamic knee valgus and, abdominal and hip abductor muscles activation. Methods Eight healthy basketball players (12 legs) participated in this study (age: 20.7 ± 1.2 years, height: 166.0 ± 9.1 cm, weight: 57.3 ± 7.2 kg). The subjects performed single-leg squats of both the right and left legs. This procedure was recorded using a 3D motion capture (VICON) and surface electromyography (EMG). Knee abduction and flexion angles were measured using the VICON. Surface EMG data was recorded for each external oblique (EO), transversus abdominis-internal oblique (TrA-IO), rectus abdominis (RA), erector spine (ES), gluteus medius (GM) and tensor faciae latae (TFL) muscles. Each EMG activities were calculated the root mean square for 1 second until maximal knee flexion, and normalized by maximal voluntary contractions. Pearson's correlation coefficient was used to examine correlations between each EMG activities and the 3D kinematic variables. The significance of differences in muscle activation between weight bearing and non-weight bearing sides during single-leg squats was analyzed using Mann-Whitney U test. Statistical significance was established at a level of $p < 0.05$. Results There was no statically significant relationship between knee abduction angle and muscle activation. RA and ES activations in non-weight bearing side were greater than in weight bearing side (RA: $p < 0.02$, ES: $p < 0.01$). GM activation in weight bearing leg was greater than in non-weight bearing leg ($p < 0.01$). Discussion It was interesting that the EMG activities in non-weight bearing side were great not so much for local muscles but for global muscles such as RA and ES. Kagaya et al. (2015) reported that a dynamic Trendelenburg test (DTT) positive which observed contralateral pelvic drop was about 30% of the legs in single-leg squats, and the dynamic knee valgus was twice as high in the DTT-positive group than in the DTT-negative group. In the future, increasing a number of subjects and considering not only sex but also influence of DTT are needed to find out associations between dynamic knee valgus, and abdominal and hip abductor muscles activation during single-leg squats.

USING TIME TO EXHAUSTION IN THE UNIVERSITÉ DE MONTRÉAL TRACK TEST TO EVALUATE MAXIMUM OXYGEN UPTAKE IN THE TRACK FIELD FOR FEMALE MASTER RECREATIONAL RUNNERS

BONET, J.B., ALAMO, J., VISCOR, G., PAGÈS, T., MAGALHÃES, J., TORRELLA, J.R., JAVIERRE, C.

Universitat de Barcelona

INTRODUCTION Over the years, coaches have used many different field tests to assess indirectly maximum oxygen uptake (VO2max) since it has an important relationship with running performance. Due to its simplicity and feasibility, one of the most well-known progressive incremental field tests for runners is the Université de Montréal Track Test (UMTT) (1). The purpose of our study was to validate the use of time to exhaustion (TE) to determine VO2max in the track field for female master recreational runners. We obtained, after performing UMTT in a treadmill in the laboratory, a formula that correlates both variables. METHODS Forty-two women (mean age 40 ± 7 years), trained for recreational running, performed a UMTT in a treadmill until exhaustion. Ventilatory parameters and heart rate were continuously monitored and tVO2max (treadmill VO2max) and tTE (treadmill TE) were obtained. The same UMTT was performed in a track field recording fTE (field TE). After checking the significant correlation between tTE and fTE, the association between tVO2max and fTE was tested with a Pearson correlation test, thus obtaining a first order equation that allowed estimating tVO2max from fTE. The mean differ-

ence between fVO_{2max} and tVO_{2max} values was also calculated. RESULTS The correlation between fTE and tTE was statistically significant ($r=0.92$, $P<0.001$) as well as the relationship between fTE and tVO_{2max} ($r=0.66$, $P<0.01$). The first order equation obtained in the treadmill for calculating fVO₂ (mL/kg/min) from fTE (seconds) was: $fVO_2=0.027 \cdot fTE + 26.953$. The mean difference between fVO_{2max} and tVO_{2max} was 0.2 ± 4.3 mL/kg/min. DISCUSSION The UMTT is a well-known progressive incremental field track test for runners. Many studies used this test to calculate fVO_{2max} from several parameters obtained in a treadmill. Most of these studies were done on populations of young (mainly male) trained athletes (1, 2, 3). Here we present a first order simple equation to estimate fVO_{2max} from a single parameter (fTE) that applies to a very specific population group: Caucasian middle-aged pre-menopause women trained at the recreational level. Since in recent years there has been a growing inclusion of women of all ages in running, this equation will provide an easy tool to obtain the maximal aerobic power in this population group. ARE CURRENT EXHAUSTION CRITERIA FOR PHYSICAL EXERCISE TESTING HIGH ENOUGH TO SUFFICIENTLY DETERMINE VO_{2MAX}?

Introduction: In physical exercise testing exhaustion is necessary to determine the maximum volume of oxygen uptake (VO_{2max}), but different criteria to define exhaustion are found in different guidelines. We compared values from three different guidelines (Steinacker et al., 2002; Tschopp et al., 2001; Rassouli and Thurnheer, 2015) for maximum heart rate (HRmax), maximum respiratory exchange ratio (RERmax), maximum rating of perceived exertion (RPEmax) and maximum blood lactate concentration (Lacmax) with values found in young male athletes. The criteria in the guidelines ranged from > 90% to >= 100% of the predicted HRmax, > 1.05 to >= 1.15 for RERmax, > 12 to >= 18 for RPEmax and > 4 to >= 8 mmol/l for Lacmax. Methods: Eighty-four males performed a cardiorespiratory fitness test on a bicycle ergometer, starting at 50 W with a linearly increasing workload of 25 W/min until exhaustion to determine VO_{2max}. Breath-by-breath gas analyses and HR were measured permanently, RPE was recorded every three minutes and blood lactate concentration was determined at exhaustion and three minutes after exhaustion. Further, VO₂ was assessed for the time points when RER reached 1.05, 1.10 and 1.15 and when HR reached 90% and 100% of the predicted HRmax. Results: Participants' median (interquartile range, IQR) age was 23 years (22; 29), maximum workload was 400 W (368; 429) and VO_{2max} was 61 ml/kg/min (56; 66). Regarding the exhaustion criteria, the median HRmax was 191 bpm (187; 197), RERmax was 1.18 (1.15; 1.22), RPEmax was 20 (20; 20) and Lacmax was 14.1 mmol/l (12.6; 15.9). The median VO₂ (IQR) at RER=1.05 was 54 ml/kg/min (50; 60), at RER=1.10 it was 57 ml/kg/min (53; 63) and at RER=1.15 it was 59 ml/kg/min (55; 54). At 90% and 100% of the predicted HRmax the median VO₂ (IQR) was 47 ml/kg/min (41; 53) and 58 ml/kg/min (50; 63), respectively. A total of 16/84 subjects did not reach RER=1.15, 13 did not reach 100% of the predicted HRmax and one did not reach Lacmax >= 10 mmol/l. Discussion: In intervention studies as well as in evaluating training effects it is crucial to determine VO_{2max} precisely. In male athletes we recommend to raise exhaustion criteria to accept exhaustion only when all of the following four criteria are fulfilled: HRmax >= 95% of the predicted HRmax, RERmax >= 1.10, RPEmax >= 19 and Lacmax >= 10 mmol/l. HEALTH-RELATED QOL AND SOC OF JUDO EXPERTS AND SENIOR PLAYERS

RYOSUKE, O., MORIO, S., TAIRAI, M., YUKA, K.

Juntendo University, Japan

Introduction Judo is one of the martial arts belonging to the traditional Japanese cultural practice called Budo. The ultimate goal of Judo is not the acquisition of brute strength, but rather the perfection of oneself across a lifetime through an understanding of philosophy and characteristic Kata2). Therefore, for the present study, we decided to examine the usefulness of Judo practice for health maintenance over long periods by researching the psychological characteristics and related factors of Judo experts (high rank dan holders) and long-time practitioners. The concepts that I focused on were health-related QOL (quality of life)[3] and SOC (sense of coherence)[4]. Health-related QOL is a globally recognized, credible, and valid measure of physical, mental, and social well-being. In contrast, SOC is a relatively recently recognized concept that refers to "strength of mind" or stress tolerance ability; it is a psychological characteristic that tends to differ according to each person's way of life. The degree of SOC is believed to be strongly connected to lifelong enjoyment of mental health. For the present study, I investigated the usefulness of long-term Judo practice by researching the relation between these two concepts and martial arts practice. Methods For this study, we conducted a questionnaire survey. The survey subjects were 3rd dan through 7th dan rank holders who had participated in a Judo high rank dan holders' competition held in Tokyo. The questionnaires comprised the SF-12v25), a health-related QOL scale developed by Fukuhara; the shortened version of the SOC scale developed by Yamazaki[4]. The survey was conducted on November 1, 2015. Results The results showed that for the SOC scale, the average scores for all three factors were higher in the 60+ age group ($n = 31$) than in the <60 age group ($n = 18$). For health-related QOL, we divided the sample into five 10-year age groups, ranging from the 30s to the 70s ($n = 9$ for ages 31–40, $n = 2$ for ages 41–50, $n = 7$ for ages 51–60, $n = 23$ for ages 61–70, $n = 8$ for ages 71–80), and compared the average scores of each of the 8 factors with the national average[3] among the age groups. The comparison results showed that, while the 30s age group exceeded the national average in only one factor (generally sound outlook), the number of factors that surpassed the national average increased with participants' age. The 70s age group exceeded the national average for all eight factors. References 1)Inoue S. Born of the Budo [in Japanese]. Yoshikawa Kobunkan. 2004 2)Murata N. RELATIONSHIP BETWEEN THE OBJECTIVE AND SUBJECTIVE EVALUATION OF CHILDREN'S PHYSICAL ACTIVITY LEVEL BY THEIR PARENTS AND NURSERY SCHOOL TEACHERS

ISHIZAWA, J.1, SASAKI, R.2, YOSHITAKE, Y.3

1: Soai Univ. (Osaka, Japan), 2: Keio Univ. (Yokohama, Japan), 3: Nat Inst Fitness Sports in Kanoya (Kanoya, Japan)

Introduction Physical activity (PA) is an integral part in children's development education. Researches have clarified the importance and benefits of conducting physical activity in early year's education. PA has been associated with health and movement ability in preschool children (Harriet G. et al. 2008; Fisher et al., 2005 ;Kagaya et al., 2003). This study examines the relationship between objective and subjective evaluation of children's PA level from the parents' and teachers' perspectives. Methods 214 nursery children (mean age, 5.7 ± 0.6 years) participated in this study together with their parents and nursery school teachers. An objective PA assessing the level of children's activity was conducted using a triaxial accelerometer (Active Style Pro, Omron) for seven consecutive days. A subjective assessment using a questionnaire on parents' and teachers' perceptions of the children's level of activeness comprising four categories was conducted. The relationship between the objective PA and the subjective evaluation was investigated using correlation analysis. Results The results indicate that parents had a higher ratio when evaluating the child as "active", while the teachers were more likely to evaluate the child as "scarcely active," or "inactive." The teachers' evaluation results correlate with the step counts and the MVPA on weekdays, but only the MVPA in the weekend. The parents' evaluation results have a weak correlation with the MVPA on weekdays, and no correlation in the weekend. Discussion These findings suggest that both parents and teachers could detect the children's actual PA level to a certain degree (Tanaka et al. 2013). In addition, their evaluation was primarily focused on the children's MVPA. However, the parents tend to consider their child "more active" as compared to the teachers. Further research can identify the underlying factors of the varying evaluations between parents and teachers toward a child. References Harriet G. et al. COMPARISON OF PHYSICAL FITNESS OF CHILDREN BETWEEN TWO DIFFERENT AREAS OF SNOW COLD REGIONS IN JAPAN

NAGATANI, M., YOKOYAMA, A., IDE, K.

Hokusho University

Introduction A decline in physical fitness of children has become an important issue as a social problem in Japan. The issue is serious especially in snowy cold regions such as Hokkaido in Japan, as snowy cold environment may limit physical activity. In fact, physical fitness of children in Hokkaido has been consistently the lowest over Japan. In contrast, physical fitness of children in Akita which is also located in such snowy cold regions has been one of the highest five. Therefore, the aim of this study was to compare factors that may cause the difference in physical fitness of children between Akita and Hokkaido both of which are located in snowy cold regions in Japan. Methods We collected data comprising number of coaches, junior sports clubs, ratio of coaches to junior sports clubs, and physical fitness of children in Hokkaido and Akita. Moreover, we investigated contents of sports promotion each local government did by interviewing. Results Physical fitness of children in Hokkaido was the lowest, whereas that in Akita was one of the highest five over Japan in 2015. There were 2,104 junior sports clubs with 8,984 registered-coaches in Hokkaido. On the other hand, there were 832 junior sports clubs with 7,849 registered-coaches in Akita, indicating that ratio of sports coaches to children can be greater in Akita than that in Hokkaido. Moreover, it was found that they secure time to do exercise indoor besides physical education classes during a snow cover period in Akita. Discussion There was an apparent difference in physical fitness of children between Akita and Hokkaido. Physical fitness of children in Hokkaido may be affected by snowy cold environment that may limit physical activity. However, it appears that such limitation has been overcome in Akita. They secure certain time and place to do exercise besides physical education classes using free classrooms effectively at school. For example, they regularly do exercise using a free classroom before the first class. Moreover, they appear to have more opportunities to learn and play sports under coaches instead of school teachers after school in Akita compared with that of Hokkaido. Therefore, it is suggested that they need to overcome environmental factors to help enhance children's ability, as physical fitness would be affected by environment. EFFECTS ON VERTICAL JUMP ABILITIES OF ELEMENTARY STUDENTS DURING PROGRAMMING PLAY IN THE MORNING

OMIYA, S., TAKEDA, T., MASHIYAMA, N., ISHII, Y., YAMAMOTO, K., HAREYAMA, S.

Hokusho University

Introduction The decrease of physical fitness and ability in children are pointed out in Hokkaido, Japan. We conducted practical research about the physical fitness improvement in elementary students in Ebetsu city where our university is located. The purpose of this study is to clarify the effect on vertical jump abilities of elementary students during programing play in the morning. Methods The subjects were students 28 students (19 boys, 9 girls) in 2013 and 22 students (10 boys, 12 girls) in 2014, all in the first grade of elementary school. Each "morning exercise" program was designed for the subjects and the morning exercise program was carried out 27 times in 2013 and 18 times in 2014, from May to December respectively. These programs were taught by the university students who were aiming to become teachers. These morning exercise programs were made for the purpose of physical fitness improvement and enjoyment for the students. Two vertical jump performance tests, a countermovement jump(CMJ), and repeated 5 times rebound jump(5RJ) on a mat switch system had been carried out before (in May) and after (in December) the program. CMJ and 5RJ abilities were evaluated by jump height and RJ-index (= jump height [RJ-H] /ground contact time [RJ-CT]), respectively. Statistical differences between the values of before the program (in May) and after the program (in December) were determined by the T test (both sides). Differences with $p < 0.05$ were considered significant. Results In 2013, the boys had significant increased in CMJ and RJ abilities but the girls had not in comparison between before and after. In 2014, boys and girls had both increased in CMJ and RJ abilities. Discussion In 2013, the boy's CMJ and RJ ability improved, but it did not improve for the girl's ability during the 27th exercise programs had no play jumping frequency. In 2014, despite the fewer number of subjects than in 2013, more subjects increased in their jumping ability, jumping exercise play programs held more often. This is thought to be because it contained a lot of short contact time in the jumping exercises. References Takeda, T et al. (2014). Bulletin of Hokusho University School of Lifelong Sport, 5,1-14. EFFECTS OF DIFFERENTIAL AND TRADITIONAL TEACHING METHODS IN CHINESE HEALTH QIGONG ON CONCENTRATION, MINDFULNESS AND EMOTIONAL STATE

HELLMICH, A.C., HENZ, D.

University of Mainz

Introduction Current research lists a high number of pupils who have behavioural problems and are unable to concentrate properly (DuPaul et al., 2011; Hetherington et al., 2006). The objective of the study was to explore whether different teaching approaches (traditional repetition-based, differential learning) in the dynamic Chinese Health Qigong technique Wu Qin Xi (Five Animals Play) have different effects on the pupils' concentration, mindfulness, and the emotional state. Methods N = 108 female pupils (mean age = 11) were examined. Four classes performed the dynamic Qigong technique Wu Qin Xi, applying two different teaching methods: the differential learning method and the traditional repetition-based method. The development possibly caused by Qigong was examined using three different tests: concentration (test of attention and concentration d2-R), mindfulness (mindfulness questionnaire of the city Freiburg) and emotional state (Multidimensional questionnaire about the emotional state). The attitude of the pupils towards Qigong was explored by a self-constructed questionnaire, which was evaluated by Mayring's qualitative content analysis (2010). The pupils' state was analysed before and after five Qigong lessons using MANOVAs. Results The study revealed benefits for the concentration in all participating classes (differential learning: $p < .008$; $p < .007$; traditional repetition-based method: $p < .000$; $p < .000$). However, there were no statistically significant effects on mindfulness and the emotional state. No effect was found concerning the teaching method. Qigong was equally liked and disliked by the pupils with 36% of the pupils opting to continue their practice of Qigong. Discussion As a result, Qigong may be considered an option to improve the pupils' concentration in both teaching techniques. However, it remains to be explored further, whether regular exercise of the dynamic Qigong technique Wu Qin Xi offers an improvement to mindfulness and the emotional state of pupils as well. To exclude effects of maturation on attentional performance, an additional control group should be tested. References DuPaul GF, Helwig JR, Slay PM (2011). CONDITIONAL SKILL DEVELOPMENT IN PHYSICAL EDUCATION

BODÓ, D., SOÓS, R., WILHELM, M.

University of Pécs - Faculty of Sciences

Introduction: The general goal of physical education (PE), besides giving experience of different kinds of sports and developing an overall personal movement culture, showing the way to a healthy lifestyle, prevention, and giving individuals a daily opportunity to develop their motorskills and performance. According to the basic biological principals used in movement practice, there should be some kind of measurable progression of performance. Nowadays the applied physical education curriculum in Hungary needs some improvement to offer an appropriate possibility for the achievement of the expected goals. Therefore, the aim of this study is to examine the effect of some modifications in the physical education curriculum, using only individually differentiated bodyweight exercises, allowing progression in maximal strength, strength-endurance, postural corrections and prevention, coordination, and also sport specific skills. **Methods:** The first section (8-10 min) of every PE lesson is started with: joint mobility as general warm up (2-3 min); warm up, training set of bodyweight exercises (5-8 min); and a transition set of bodyweight exercises related to the actual sport that is going to be taught (2-3 min). The body-weight exercises are push up, pull up, one legged squat, and bridge. Exercises are differentiated by their difficulty, that allows progression steps, and individual differentiation also. The subjects are adolescents from 7th to 12th grade. At the school, before, during, and after the study period we measure the postural situation with FMS (Functional Movement System) screening method, the intensity of the lessons with Polar Team System, and strength-endurance with bodyweight exercises. At the laboratory, we measure with the aid of a dynamometer (Multicont II isokinetic device), the level of maximal strength development in case of musculus biceps brachii, latissimus dorsi, quadriceps femoris, and biceps femoris, and with EMG during the actual bodyweight exercise performance. **Preliminary Results:** The pilot study was done in 2015, including 30 lessons in 11 weeks. We measured 19 subjects. Preliminary results suggested that maximal strength significantly increased in upper and lower extremity, and the performance of the exercises highly improved. Improvement in the most difficult push up and squat variations by number of students able to preform the exercise, and percentage of performance quality improvement: Assisted one arm push up: before: 5, after: 12, performance improvement: 75,9% One arm push up: before: 1, after: 6, performance improvement: 85,3% Half one legged squat : before: 5, after: 10, performance improvement: 69% Full one legged squat: before: 2, after: 10, performance improvement: 75,6% **Discussion:** According to our preliminary results we expect that long term progression strength training in physical education curriculum is effective in developing maximal strength and strength-endurance, coordination, and postural correction.

LOW BACK PAIN IN PROFESSIONAL VOLLEYBALL AND HANDBALL PLAYERS

FRANGEŽ, M., KOS, N.

University Medical Centre Ljubljana

LOW BACK PAIN IN PROFESSIONAL VOLLEYBALL AND HANDBALL PLAYERS Introduction Low back pain frequently affects professional athletes and it can seriously hinder their performance. One has to be familiar with trigger factors, physical characteristics of the athlete, his/her age and the type and characteristics of the sport as all of these contribute to low back pain. The aim of our prospective study was to establish the frequency of low back pain in professional volleyball and handball players. **Methods** The study included professional athletes competing in volleyball or handball. We devised a survey questionnaire to obtain demographic data, present and average low back pain and the information on frequency of low back pain. The intensity of the pain was assessed using the Visual analogue scale. The questionnaire was filled in by the specialist of physical and rehabilitation medicine. **Results** The study included 38 professional volley-

ball or handball players with average 9,4 years of professional sport career. They were in average 23 years old. 31 athletes (82%) reported having LBP in the past. In the opinion of 27 athletes (87%), their first experience of low back pain was related to their sport activities. 28 athletes (90%) thought that LBP has a negative effect on their performance in sport activities. 23 athletes (74%) used physical and rehabilitation medicine methods for treatment of low back pain. Discussion With the help of the survey questionnaire we established that the low back pain is common in professional volleyball and handball players in Slovenia and hinders the athletes performance. When treating an athlete with low back pain, who is motivated to make a speedy recovery in order to re-enter training and competitions, we have to take into account the biomechanical factors and include them in the rehabilitation program (Trainor, 2002). The program should concentrate on specific goals to reduce low back pain and allow a safe return to sport activities. References Trainor TWS. (2002). Clinics in sports medicine, 21 (1): 93-103.

CHAMPIONS' TACTICS: DO THEY DIFFER FROM THOSE OF OTHER COMPETITORS?

WU, Y.T., LIU, Y.T.

Exercise and sport science

Introduction Taekwondo is a full contact sport where most points are scored through kicks (Kazemi et al., 2006). Taekwondo athletes use various types of kicks in matches and these different kicking techniques have different scoring efficiencies (Tan & Krasilshchikov, 2015). A series of matches has to be won in order to warrant a gold medal in a Taekwondo competition. Do Taekwondo champions use different kicking tactics from other competitors? The purpose of the study was to examine the kicking tactics between the champions and other competitors in Taekwondo competitions. Methods Video files of the 2015 Taekwondo Grand Prix Final from the Internet were used in the study. Matches of 8 athletes per weight category were analyzed using the Simi Scout behavioral and tactical analysis system. Four individual kick tactics, Roundhouse kick (R), front-leg roundhouse kick (F), pushing kick (P), back kick (B), and others (O), as well as the combination tactics of any 2 of the individual kicks were registered by 2 black belt Taekwondo experts for both athletes of each match. The number of occurrences of each type of kick tactics for gold medalists (champions) and other competitors was analyzed. Results There were no differences in the amount of tactics used between the single and combination tactics for either the gold medalists or other competitors. F had the highest amount of occurrences for both groups in the single tactics, while the gold medalists also showed a highest frequency of F+F among all the combination tactics. The P kick was the 2nd/3rd highest single tactic for the gold medalists/other competitors, and the R kick was the 3rd/2nd highest single tactic for the gold medalists/other competitors. In addition to the F+F combination, other high frequency combinations that were used in both groups were P+R, P+F, and F+R. Discussion The front-leg roundhouse kick has been considered as a difficult technique to perform but it can be very useful in scoring points (Lee, Chin & Liu, 2005). In high-level Taekwondo competitions such as Grand Prix Final, F appeared to be the most used of the single tactics. Furthermore, the gold medalists most frequently used the F+F tactic, which was not observed as frequently in other competitors. From the four most frequently used combination tactics, we also observed that the front-leg roundhouse kick was the only one used in both the initiation and the follow-up segments. The findings of the study suggest that the Taekwondo champions exploit the front-leg roundhouse kick tactic to a fuller extent and the tactic may be one of the important factors that lead to their success. STATISTICAL ANALYSIS OF DECATHLON: A NEW APPROACH.

CIACCI, S., PASSARELLI, A., MERNI, F.

University of Bologna

Introduction Decathlon is one of the most challenging disciplines in track and field. Previous studies have assessed the relationships between the performance in the 10 decathlon events by means of correlations or cluster analyses (Woolf et al, 2007, Cox et al, 2002, Van Damme et al, 2000). The aim of this study was to assess the correlations between the 10 decathlon events and the final competitive outcome, with particular focus on possible strategies used to achieve the final score by athletes of the most represented nations in the top 100 all-time world ranking. Methods The 100 world top (all-time) decathlon performances (taken from IAAF scores) were analysed. Scores achieved before the change of the javelin throw rule in 1986, have been compared to the results obtained after 1986, after standardization of the different throwing results according to Borgström (2000). The ranking has been analyzed to investigate how the different events are clustered and affect the final score. Furthermore, the data of the 3 states with the highest number of athletes in the all-time list (Russia, Germany and USA) were compared to study how their training strategies may affect the final performance. Results In agreement with previous studies (Cox et al, 2002, Woolf et al, 2007), the analysis showed two main clusters observed in the dendograms. The 100m, 110m hurdles and long jump belonged to the same cluster and their scores were well correlated with the final results (r between 0.536 and 0.564). The shot put and discus throw were linked to another cluster, and were not correlated with the final score. The javelin throw, the pole vault and the high jump showed a weaker relationship with the final score, probably due to the high level of technical skill required. There were no significant differences between the three examined nations , with the exception of the average 100m and 1500m results between Russia and USA (851 pts vs. 892pts, and 745 pts vs. 702 pts, respectively). Discussion The results show that the sprint events influence the decathlon performance more than other events. This outcome may be taken into account to select talents and develop a more effective training programs. Among the 3 examined nations, USA showed higher score than the Russia especially in the sprint events and consequently in the final score. Russia showed better scores in the throwing events and 1500m race. Finally, athletes from Germany were generally ranked between those of the other 2 nations in all the decathlon events. COLLECTIVE PERFORMANCE IN RUGBY UNION: XV DE FRANCE VS NEW-ZEALAND.

SAULIÈRE, G.

INSEP

Introduction: Rugby performance depends on the individual capacities of the players and also is strongly influenced by physical and tactical cohesion of the team. It is hypothesized that rugby men who have played with each other throughout their carrier will be more effective during a game than those who haven't. Our aim is to evaluate team performance throughout a quantitative analysis of team cohesion of the XV de France and the All Blacks. The study focuses from 2000 to 2015, to set against four collective constructions of the

last four rugby world cups. Methods: Names, positions, age and numbers of selections, dates, opponents, scores and match venues were collected for all XV de France and All Blacks games from 1987 up to 2015. We computed the number of cumulated shared selections for each match as a key collective performance indicator. For each game, we quantified the number of selections that each player has shared with the others. Results: 235 French players were involved in 183 matches during the studied period against 184 New-Zelanders in 202 matches. The values of cumulated shared selections fluctuate strongly between the competitions, ranging from 100 to 1600 for the French team and 100 to 3200 for the team of New Zealand, with greater values of shared selections during the world cups and a minimum during the tests matches, suggesting a team pattern for the world cups. The performance indicator increases between two world cups, except for the XV de France during the last edition (1042 for the French against 3156 for the New-Zelanders) where the XV de France didn't pass the quarter final. This evolution illustrates the building of a group becoming more and more experimented for the prestigious competition. Conclusion: Collective performance in rugby union is based on a balance between young players at the peak of their physical performance and older and more experienced players indispensable to the tactical group cohesion and its optimal operation.

COMPARING THE SPATIAL INFORMATION IN OFFENSIVE STRATEGY AND SCORING STYLE BETWEEN WINNING AND LOSING TEAMS OF BASKETBALL GAMES

LAN, Y.C.1, LIU, Y.T.2

1: NYMU (Taipei, Taiwan), 2: NTNU (Taipei, Taiwan)

Introduction In basketball games, coaches deploy offensive tactics on different locations on the court (Atkins, 2004). Scoring in the lane is very important but shooting from the perimeter also contributes to a successful game (Tseng, 2011). Could the outcomes of the games attribute to the patterns of shooting/scoring locations on the court? The purpose of the study was to use the principal component analysis (PCA) to identify and compare the offensive tactics in basketball games based on the shooting and scoring zones between winning and losing teams. Methods All games (n= 32) from 2012-2014 Taiwanese University Basketball Association (UBA) men's division 1 were recorded and a total of 5296 shootings were analyzed. The court was divided into five zones (Z1: the lane, Z2: 2-point high zone, Z3: 2-point low zone, Z4: 3-point high zone, Z5: 3-point low zone). Two independent observers recorded all the shots and the Cohen's Kappa for intra and inter-rater reliability was 0.9 and 0.78, respectively. PCA was performed on the shooting zones and scoring zones for the winning teams and losing teams. Results For the shooting zones, both winners (85.38%) and losers (86.89%) had 3 PCs that had eigen values larger than 1. For the winners, PC1 (36.46%) consisted of Z1 and Z5, PC2 (27%) consisted of Z3 and Z4, PC3 (21.93%) consisted of Z2. For the losers, PC1 (38.97%) consisted of Z1, Z5, Z4, PC2 (26.51%) consisted of Z3, PC3 (21.41%) consisted of Z2. For the scoring zones, winners had 3 PCs (86.72%) and losers had 2 PCs (69.78%) that had eigen values larger than 1. For the winners, PC1 (31.69%) consisted of Z1 and Z4, PC2 (31.59%) consisted of Z5 and Z2, and PC3 (23.45%) consisted of Z3. For loser, PC1 (43.04%) consisted of Z1, Z4, and PC2 (26.74%) consisted of Z3 and Z5. Discussion Based on the shooting zones results, in addition to the lane and the 3-point offensive strategy that both the winning teams and losing teams had, the winners showed another offensive pattern, which included the low post zone and the high 3-point zone. The results from the scoring zones also showed similar patterns for the winners and losers where both the lane and the 3-point high zone had the highest contributions. However, the opposite signs of the coefficient of the 2 zones for the losing teams indicated that the scoring contributions of the 2 zones were negatively correlated whereas the scoring contributions for the 2 zones from the winning teams were positively correlated. Generally speaking, both winning teams and losing teams had similar offensive strategies in terms of the shooting and scoring deployment. It is the results of the offensive strategies that determined the outcomes of the games. Reference Atkins, K. (2004). Basketball: Offences and Plays. Champaign, IL: Human Kinetics. Tseng, K-T. (2011). The road to success for bench coach: dynamic analysis of offence tactic and strategy in basketball. Unpublished master thesis, NTNU, Taipei, Taiwan. Contact yclan@ym.edu.tw

HAND POSITIONING EFFECTIVENESS IN BLOCKING IN HIGH-LEVEL FEMALE VOLLEYBALL

GABELLINI, L.1, PALLADINO, L.2, BURATO, E.2, MERNI, F.1

1Department of Biomedical and Neuromotor Sciences University of Bologna; 2University of Bologna

INTRODUCTION The teams use the block as a first defensive action that could also bring to a direct-point realization (Mesquita and César, 2007). The purpose of this study was to analyse a selection of technical/tactical aspects of volleyball blocking with particular focus on the single hand involved in the block. This analysis would allow to elucidate some key characteristics of blocking and to study the strategies used by attackers against the block. METHODS The study sample consisted of 2128 blocks from 65 matches during the Women's Volleyball World Championship - Italy 2014. Only attacks from zone 2 and zone 4 were examined. The considered variables were: The contact between the ball and the two blockers, for which a code was specifically created to distinguish every single hand (1-4 for the external hand of the outside or middle-blocker respectively, 3-6 for the internal hand), and both hands of one player hit simultaneously (2-5). Block outcome (Peña et al 2013): winning (direct point), positive (ball played again by the home team), poor (ball played again by the opponents), and error block (opponents' point). To test the relation between the variables, chi-square tests were used. RESULTS When the attack was performed from zone 2, the external blocker was hit more frequently than the internal one ($p<0.01$); specifically, in most cases, his hands were hit individually rather than simultaneously ($p<0.01$). Conversely, there wasn't a large difference between the number of times the ball touched each blockers when the attack was from zone 4. In the first case, when the external hand of the outside blocker was hit, a blocking error often occurred (58%), whereas in fewer cases there was a direct point (11%). Conversely, when the internal hand was hit, the more frequent block outcome was winning (33%) ($p<0.01$). With reference to attacks from zone 4, the less searched direction was clearly the one leading to hit both hands of the middle blocker ($p<0.01$). When the external hand of the outside blocker was hit, the block outcome was in most cases a blocking error (57%), while poor blocks (11%), positive blocks (16%) and winning blocks (16%) occurred in fewer cases ($p<0.01$). Moreover, when the attackers hit both hands of the outside blocker, they were less likely to make a point. DISCUSSION The effectiveness of the block changes depends on which hand is hit by the attacking player. The hand hit more often by attackers, regardless of their position, is always the external one of the outside blocker since it's closer to the side-line of the court. In this case, more than 50% of times the attacker scores. In practice, these observations can be employed to improve the block technical/tactical and the attack strategies, knowing the best attack direction. REFERENCES Mesquita I, César B (2007). AEROBIC PHYSICAL ACTIVITY ASSESSED WITH FOUR DIFFERENT METHODS IN FINNISH POPULATION SAMPLE

HUKKANEN, H., HUSU, P., SIEVÄNEN, H., TOKOLA, K., SUNI, J., VÄHÄ-YPYÄ, H., VASANKARI, T.

The UKK Institute for Health Promotion Research

Introduction Studies use a variety of self-assessment methods and objective devices to measure physical activity (PA), but agreement between these methods is poorly understood. In recent decades, technical development has offered objective tools, such as accelerometers to assess PA. Yet there is a need to better understanding, what we are actually measuring. The aim of this study was to determine the agreement between accelerometry, diary, questionnaire and interview in assessing weekly time spent in moderate to vigorous physical activity (MVPA) minutes. Methods Participants of the PA and fitness subsample of the Health 2011 Study were given an accelerometer (Hooke AM 20, Traxmeet Ltd, Espoo, Finland) and a diary for seven day measurement. They also filled in questionnaire and were interviewed about their regular weekly PA. Participants were asked to report the average frequency and duration of moderate and vigorous aerobic activity. These intensities were combined as MVPA minutes. All the methods included PA lasting at least 10 minutes at a time. Paired samples t-test was used for statistical comparison. Results Adult participants (18-75 years old) who had sufficient accelerometer data (at least 10 h/day for 4 days) were included in to the study (n=1489). The mean age of the participants was 51 years (SD 14), 57.4% being women. The highest amount of MVPA minutes was obtained from interview and questionnaire (153min/wk), while the lowest amount was obtained from diary (106min/wk). There was statistically significant difference between accelerometry and PA diary (13min/wk, p<0.001), accelerometry and questionnaire (-43min/wk, p<0.001), accelerometry and interview (-42min/wk, p<0.001), diary and questionnaire (-54min/wk, p<0.001) and between diary and interview (-55min/wk, p<0.001) in total weekly MVPA minutes. There was no difference in total MVPA minutes between PA questionnaire and interview (2min/wk, p=0.693), but there was huge individual variance between the methods. Discussion Different PA assessment methods yielded highly varying results of weekly amount of aerobic MVPA. Especially at the individual level, inter-method differences were huge. Obviously the PA measurements reflect different issues; measured activity vs recalled behavior over different timeframes. In conclusion, results obtained from different PA assessment methods are not interchangeable and their interpretation must be done with caution. Contact Henna.Hukkanen@uta.fi

Adapted Physical Activity

COMPARISON OF PHYSICAL ACTIVITY ATTRIBUTABLE TO NEIGHBOURHOOD ENVIRONMENT BETWEEN CHILDREN IN AN EARTHQUAKE- AND TSUNAMI-AFFECTED AREA AND THOSE IN UNAFFECTED AREA

OKAZAKI, K.1, SUZUKI, K.2, SAKAMOTOA, Y.1, OHKAWARA, K.3, KOYAMA, Y.4, SASAKI, K.1

1: Tohoku Gakuin University (Japan), 2: Juntendo University (Japan), 3: University of Electro-Communications Visiting Scholar (Japan), 4: Seikei junior high school (Japan)

Introduction We compared objectively measured daily steps attributable to neighbourhood environment taken by children living in an area affected by the 2011 Great East Japan Earthquake and tsunami with those living in an unaffected area, and postulated that the physical activity (PA) of children living in affected areas had decreased. **Methods** Totally, 234 children aged 9–12 years from an affected coastal area (N=143, group AA) and a non-affected area (N=91, group OA) participated in this study conducted 4 years after the earthquake. Children reported their personal and demographic characteristics; the number of steps was measured objectively using accelerometry. Their parents reported on environmental factors pertaining to walking and bicycling in the neighbourhood using the PA Questionnaire Environmental Module (Inoue et al., 2009). **Results** The number of daily steps taken by boys in group AA was 9491, 10518 and 6840 compared with 8174, 12411 and 3856 taken by those in group OA on a weekly average, weekdays alone and weekends, respectively. The number of daily steps taken by girls in group AA was 7854, 8323 and 5330 compared with 6857, 10632 and 3545 taken by those in group OA, respectively. General linear model analysis indicated a significant association with interaction between study area and social environment for weekly steps ($F(2, 69)=3.27$, $\eta^2=0.09$) and access to destinations for steps on weekdays ($F(2, 80)=3.62$, $\eta^2=0.08$) taken by boys. **Discussion** For both genders in group AA, the number of daily steps on weekends was higher than that for both genders in group OA, whereas there was no association between subject area and environmental variables. This suggests that PA of children was more affected by other factors than the neighbourhood environment on weekends. Socioeconomic indicators and parental support were previously reported to be important in predicting children's participation in PA (Vella et al., 2014). Moreover, access to destinations should be considered for improving PA on weekdays for children living in affected areas. EPIDEMIOLOGICAL ASPECTS OF THE BRAZILIAN PARALYMPIC ATHLETES OF THE MODALITIES OF SWIMMING AND ATHLETICS

SILVA, A., SAMPAIO, R., SIMIM, M., FACUNDO, L.A., CAVALCANTI, B.A., ROCHA, E.A., PARSONS, A., MELLO, M.T.

Universidade Federal de Minas Gerais

Introduction In the last decades note to growth in the number of athletes in the Paralympic Games. In parallel to this fact, Brazil has become a world power in the sport paralímpico. Thus, the objective of this study was to map geographically the athletes of the modalities of swimming and athletics, and the type of deficiency of these athletes. **Methods** The epidemiological aspects of paralympic athletes were collected during the three stages of the Circuit Boxes Lottery, competition organized by the Brazilian Paralympic Committee (CPB) in the city of São Paulo, in the months of July, September and November 2015. In the initial database had a total of 2.354 athletes, distributed in three phases competitive. However, were excluded from the analysis the athletes (646 athletes) who were with duplicate names. **Results** The sample of 1.708 athletes (men: n = 1.076; 63% and women: n = 632; 37%), 913 (53.5%; men: n = 539; 59% and women: n = 374; 41%) are the modality of swimming and 795 (46.5%; men: n = 537; 67.5% and women: n = 258; 32.5%) of the modality of athletics. In relation to disability observed predominance of athletes with physical disability (n = 1.118; 65.5%), followed by visual deficiency (n = 429; 25.1%) and of intellectual deficiency (n = 161; 9.4%). In relation to the geographical distribution of these athletes, it was observed that the majority of the Southeast region (n = 1.122; 66%), followed by the southern regions (n = 189; 11%), Northeast (n = 188; 11%), Midwest (n = 159; 9%) and North (n = 50; 3%). **Discussion** The Brazilian region with higher percentage of paralympic athletes in the modalities athletics and swimming is the Southeast. This region is composed by cities that historical context are responsible for the implementation of the Paralympic sport in Brazil (Araújo, 2011). The predominance of physical disability can be attributed to the greater number of sports classes directed to this type of disability (IPC, 2016th a, 2016TH B). This information will contribute to the development of Paralympic sport in Brazil, mainly in the implementation of public policies. From the point of view competitive, this mapping serves as a guiding the actions of CPB in the improvement of infrastructure and in the routing of the training system. References Araújo, P. F. THE MOVEMENT SPEED OF DURING THE GAME IN AMPUTEE SOCCER

MAEHANA, H.1, IGUCHI, Y.1, MIYAMOTO, A.1, HORIIKE, T.1, KOSHIYAMA, K.2, YOSHIMURA, M.1

1.Juntendo University 2.Iwamizawa Campus Hokkaido University of Education

Introduction Amputee soccer activities are comprised of varying explosive movements like forward and backward shuffles, runs at different intensities and sustained forceful contractions to control the ball against defensive pressure). As with soccer player, which had less time with the ball, players should have spent a lot of time to move. However, there is no indication of the movement speed in amputee soccer. It is possible to evaluate the performance by creating an index of the movement speed. Appropriate training plan is devised by evaluating a performance. The present study was aimed to evaluate the measured performance of the movement speed during the game in amputee soccer players. Methods Twelve male amputee soccer players with unilateral lower limb amputees participated in this study voluntarily. In amputee soccer, matches are played between teams of seven players using bilateral crutches. Wearing a prosthetic device is not allowed during match play. The match is played in two equal periods of 25 minutes each. The half time interval must not exceed 15 minutes. The size of the coat is a 70m × 50m. To measure the movement speed during the game based on the above official rules. Match activity data were collected using the GPS (15Hz). Results The average of the total distance was significant longer in the first half compare with the second half (1721.8m vs. 1398.4m, p<0.05). The movement distance with Walking (0.4-5.0km/h) was longest in both the first half and the second half. The movement distance was significant higher in the first half compare with the second half in Moderate intensity Running (8.0-13.0km/h) (584.6m vs. 421.6m, p<0.05). During the game had a higher rate to move below 13km/h. No significant difference between the first half and the second half was observed in Maximum speed, frequency of High intensity Running and distance per one time of High intensity Running. Below-knee amputation had 0.9km/h faster maximum speed, and 30cm longer in distance per one time of High intensity Running compared with Above-knee amputation. Discussion The finding of the present study was suggested that high percentage to move in the following 13km/h during the game, and there was the influence of limb length difference of the remaining portion in the amputation level. RELATIONSHIP BETWEEN THE SUBJECTIVE EFFORT AND THE OBJECTIVE PERFORMANCE IN BADMINTON SERVICE AND THE GRIP:IN THE CASE OF THREE PARA-BADMINTON PLAYERS IN JAPAN

KANEKO, M., MORIKAWA, H.

TOYO University, TEIKYO-HEISEI University

Introduction It has been recognized that various adjustments with human movement are performed with the help of the subjective sense of the players. But in many cases, it has been felt that the subjective sense and the real performance do not correspond. If a coach has got a good understanding the error, which has been occurred between the subjective sense and the real performance beforehand, it would help a coach that provide their players coaching. Then we investigated those as to the university and junior high school badminton players(2006,2009,2012). And we showed that there were a linear relationship between the subjective effort and the relative performance. Furthermore when a coach without any disabled that provides their para-athletes coaching, it is important all the more. Therefore, the purpose of this study was to investigate the relationship between the subjective effort and the relative performance, in case of the physical disabled badminton players. **Method** The subjects of this study were three well-trained athletes with a physical disabled (upper limbs obstacle player, lower limbs obstacle player and wheelchair player). All the members were male. And they had been higher winning prizes in international badminton meetings. The two kinds of experimental attempts were the service in badminton and the grip with the dominant hand. The subjects performed both experimental attempts at five different subjective efforts range 60% to 100% in the sequence of ascending and descending. The shuttle speed were measured using a high-speed camera (250fps) and an analysis software, FRAMEDIAS(DKH, JAPAN). The relative performance were calculated the ratio of performance for subjective effort 100%. **Result** In case of service in badminton, the relative performance corresponded to 61.2, 71.1, 79.8, 89.6, 100.0, 77.9, 86.7, 77.0, 68.4% in each subjective effort. In case of grip, the relative performance corresponded to 50.5, 54.2, 71.2, 82.4, 100.0, 92.5, 85.4, 80, 2, 69.0% in each subjective effort. **Discussion** As a whole, we observed that the relative performance became increasing with increasing in the subjective effort, and the relative performance became decreasing with decreasing in the subjective effort. We recognized that the subjective effort and the relative performance did not correspond in both experimental attempts. However, in subjective effort 80 and 90% of ascending in the service, the relative performance almost corresponded to the subjective effort exceptionally. And in the service of ascending process, the error was smaller, and then, in descending process, the error were larger and more excessive performance. On the other hand, in the grip of ascending process, we observed that the error tended to a shortage of performance. In the descending process, the error was larger and more excessive performance. We recognized that the trend of error in the service of the descending process that was similar to the grip of the descending. This work was supported by JSPS KAKENHI Grant Number 15K01606.

EFFECTS OF A PROGRESSIVE RESISTANCE EXERCISE PROGRAM ON ISOKINETIC LEG STRENGTH OF INDIVIDUALS WITH INTELLECTUAL DISABILITIES

BARROS, J.F.1, RAULINO, A.G.D.2, LIMA, R.M.3

1.Universidade Federal do Rio Grande do Norte 2.Secretaria de Estado de Educação do Distrito Federal 3.Universidade de Brasília

Introduction: Muscle strength is an essential variable for maintaining independence and quality of life. Reduced muscle strength is the main cause of impaired functional capacity of the individual with intellectual disabilities (ID). **Objectives:** To examine the effects of a resistance training (RT) program on knee extensors and flexors isokinetic peak torque (PT) in individuals with ID. **Methods:** A total of 40 subjects with ID (age 14-36 years) took part in this quasi-experimental study, who were assigned into experimental group ($n = 20$, 22.8 ± 6.3 years) and control group ($n = 20$, 20.9 ± 3.1 years). Experimental group followed a 12-week RT program, twice a week. All volunteers underwent knee extensors and flexors PT measurements using an isokinetic dynamometer before and after the intervention period. Data were analyzed using ANOVA and significance level was set at $p < 0.05$. **Results:** For right knee extension, ANOVA revealed a significant time*group interaction ($p=0.03$). In addition, it was noted significant increase in isokinetic peak torque for the exercised group ($p=0.004$) while it was not observed in the control group ($p=0.958$). For isokinetic knee flexion, although it was not observed significant time*group interaction ($p=0.306$), significant pre to post increase in the exercised group was noted ($p=0.031$) that was not observed in the control group ($p=0.441$). **Conclusions:** Twelve weeks of RT induces significant increases in knee extensors and flexors isokinetic muscle strength in individuals with ID. These findings may be important for health professionals involved in rehabilitation, sports performance or quality of

life for individuals with ID. References Nolan L. A training programme to improve hip strength in persons with lower limb amputation. *J Rehabil Med* 44: 241-248, 2012. PALMAR'S PREHENSION STRENGTH, LUMBAR AND LOWER LIMBS IN BEARERS OF MENTAL DEFICIENCY WITH AND WITHOUT DOWN'S SYNDROME

MAGALHÃES, G.L.1,2, GODOY, J.R.P.1, SOUSA, H.A.1, SILVA, A.R.1, BARROS, J.F.2

1. Federal Institute of Brasília/Presidency of Republic, 2. University of Brasília, 3. Federal University of Rio Grande do Norte

Abstract Objective: Evaluate the palmar, lumbar and lower members prehension strength in bearers of mental deficiency with and without Down's Syndrome. **Material and Methods:** Descriptive and inferential field study expo-factus. The sample was constituted by 110 individuals of the masculine gender with ages between 20 and 40 years old distributed in three groups: 40 formed the controls group (GC), for not presenting mental deficiency, 30 formed the group bearing mental's deficiency with Down's Syndrome (GSD) and 40 the formed the group bearing mental's deficiency without the referred syndrome (GDM). The data were analyzed being used the program SPSS for Windows® version 12.0. Firstly, the data were clustered so that there was a general scenery of the variables contrasting the groups (GC, GSD and GDM). The descriptive analysis of the quantitative data surfaced as a location measure (central tendency) – the Average - and as data's dispersion – the Average Deviation. ANOVA was used, comparing the matched samples to establish if there was significance difference among the groups, where the level of significance established was 0,05. **Results:** There is palmar's prehension strength prevalence in function for the right hand in relation to the left one in each and every of the studied groups; the muscular hypotony characteristic of the Down's population generates significant and preoccupying deficit of the strength in this population; there is a low correlation between palmar's prehension and lumbar strength, and also between palmar's prehension strength and the lower limbs. **Conclusion:** It's important to stimulate the practice of physical activity in that population, seeking life quality improvement and the consequential daily life activities (AVD's) performance, also offering a chance for social independence by being economically rewarded for whatever they are capable to produce. It is then placed as challenge for the public health system to include and take care of a growing population. Measures should be taken to guarantee the inclusion as well as the permanence of this population in the job market and to make conscious the professionals that assist it regarding the importance in guaranteeing the functional integrity of the muscle-skeletal system. EVALUATION OF PHYSICAL PERFORMANCE AMONG CHILDREN PRACTISING ARTISTIC GYMNASTICS, RHYTHMIC GYMNASTICS AND ATHLETICS

ARGEITAKI, P.1, MOUSTOGIANNIS, A.2, KARANASTASIS, G.1, PAPADOPETRAKI, A.1, KOLLIAS, L.1, MARIDAKI, M.1

National & Kapodistrian University of Athens

Introduction. Artistic Gymnastics, Rhythmic Gymnastics and Athletics are popular physical activities among children and also have a significant impact in health, fitness and maturation during childhood. Poor physical fitness increases the risk for obesity, chronic diseases and premature mortality among adults (Malina&Katzmarzyk, 2006). Aspects of physical performance has been examined in terms of three components: muscular strength and endurance, cardiorespiratory endurance and motor ability. **Methods.** Twenty-three children (age:10 years, height:136,35±7,14cm, mass:32,4±5,9kg BMI:17,4±2,5 kg/m², training experience 3,8±1,4 years) were assessed in terms of physical fitness. Eight children originated from artistic gymnastics (AG), eight from rhythmic gymnastics (RG) and seven from Athletics (A). Different training background was taken into consideration. Physical performance tests included handgrip strength for both arms, countermovement jump (CMJ), agility T-Test and 20m multi-stage shuttle run test, in this order. One-way ANOVA with repeated measures was used for statistics. Results. Regarding handgrip strength with right hand AG scored 8,4±1,6kg, RG 11,8±2,7kg and A 13,9±6,5kg. Values for left hand were 8,8±1,7kg for AG, 10,4±2,4kg for RG and 12,6±6,3kg for A. Jump height for AG was 28,4±4,0cm, for RG 26,4±5,1cm and for A 26,0±3,5cm. AG reported 15,8±1,7sec on agility T-Test, RG 15,1±1,2cm and A 13,9±1,3cm. Performance in 20m multi-stage shuttle run test was 975±256m for AG, 1223±158m for RG and 1217±304m for A. **Discussion.** Statistically significant differences were found among the three groups in right hand strength and T-test performance. Children practising Athletics events had a better agility and strength performance. No other differences were found among groups. All values, except handgrip strength, reported better performance compared with children practising no physical activity. Handgrip strength remains on normal values levels (Hager-Ross&Rosblad, 2002, Gortsila et al., 2013). Overall performance seems to be better among preadolescents who perform physical activities. **References.** Malina, R. M., & Katzmarzyk, P. T. (2006). Biomechanics

RELATIONSHIP BETWEEN MECHANICAL STRESS AND INJURY AROUND THE HIP JOINT DUE TO KICKING ACTION IN FOOTBALL.

MURAKAMI, K.

Sendai University

Murakami, K.1, Oda,K.1, Miyakawa, S. 2, 1: Graduate School of Sports Science, Sendai Univ.(Sendai, Japan) 2: Faculty of Sports Science, Sendai Univ.(Sendai, Japan) 3: Graduate School of Comprehensive Human Science, Univ. of Tsukuba. (Tsukuba, Japan) Objectives: In this study, we therefore analyzed the association between kick-induced mechanical stress (stress distribution) and the clinical findings of injuries around the hip joint that are known to be related to kicking actions in football. Methods: We selected 5 healthy football players, They perform the inside kick, instep kick, and infront kick 3 times each for right-footed. A three-dimensional motion analysis device was used to record their motion and measure the duration between maximum hip extension (MHE) and ball impact (BI). The motion analysis software, nMotion (nac, Japan), was used to calculate stress between hip joints and the angle of the hip joint in each kicking motion. In addition, the bone strength analysis software Mechanical Finder (RCCM, Japan) was used to analyze the computed tomography and magnetic resonance imaging data of each subject to develop a finite-element model consisting of the right ilium, sacrum, and femur. Then, stress between hip joints calculated in dynamics analysis was input as a load value into the finite-element model for the stress analysis. Results: At the time of BI, kicking actions produced a high-stress area in the pubic ramus compared with other areas. This value was an equivalent stress value generated in the area of interest (30 mm³) in the pubic ramus. Stress generated in the superior and inferior rami of the pubic bone was 3.52 and 2.94 MPa for the inside kick, 7.15 and 5.40 MPa for the instep kick, and 4.47 and 3.33 MPa for the infront kick, respectively. Discussion: The high-stress area on BI was the same area where groin pain syndrome (pubic bone marrow edema) occurs in the clinical examination of football-related hip joint injury and where stress fractures occur in pubic bone rami. Furthermore, in the BI-related area of interest (pubic ramus), the values of equivalent stress generated by the inside kick, instep kick, and infront kick in the superior and inferior rami were approximately 3 times, 5 and 4 times, and 3 and 2 times the stress created in the same area by standing by one leg (1.53 and 1.47 MPa in the superior and inferior rami), respectively. The analysis system that integrates motion dynamics into the body structure revealed the relationship between the clinical symptoms of the hip joint and previously reported kick-related injuries around the hip joint. AN INVESTIGATION OF WITHIN AND BETWEEN DAY TEST- RETEST RELIABILITY OF A NEW REACTIVE AGILITY TEST 'VECTOR' COMPARED TO THE 'GOLD STANDARD' T DRILL TEST

ALHAMMAD, A., PHILLIPS, N., DAY, R.

University of Salford

Background: This study examines the role of reactive agility tests that are often used when making decisions about the ability of athletes to return to sport after injury, rehabilitation and prevention of injury, but other factors that are sport specific, such as decision-making of reactive agility and external stimulus, are not often correlated with agility tests sufficiently. Therefore, the aim of this study is to examine the reliability of the intra test-retest of a new reactive agility test, which used timing mats to measure decision-making and task times whilst running forward, with participants reacting to a voice stimulus, as well as comparing the score with the traditional T-drill. Methods: Twenty-one healthy active subjects were included in this study. The main equipment used was Vector to measure decision making time and task time, which consists of five mats designed and built by Cardiff University. Other equipment included four cones, which marked the dimensions for the T-Drill. To collect the T-traditional test time, a stopwatch was used. Other equipment consisted of a tape measure, laptop computer and duct tape to fix mats to the floor. Within day and between days relative reliability was determined by using ICC. Results: ICC's value of using Vector to measure the decision making time in the same day was calculated to be 0.814. However, ICC's value of using Vector to measure the task time in the same day was calculated to be 0.459. ICC's value of using Vector to measure the decision making time between day was calculated to be 0.389, which is moderate. However, ICC's value of using Vector to measure the task time between days was calculated to be -0.096. No correlation was found between the T-drill and task-time as r values were 0.308. Conclusion: The Vector is reliable measurement tool for agility to measure decision making time in the same day. However, Vector is not a reliable measurement tool for agility to measure task time in the same day. Vector is not being a reliable measurement tool for decision making time and task time in different days. Vector was not a reliable measurement tool to measure task time during a reactive agility test performed by the same subject when compared against the traditional T-Test.

JUMP PERFORMANCE OF MALE VOLLEYBALL PLAYERS: COMPARATIVE STUDY AMONG AGE CATEGORIES

BUSKO, K., MAZUR-ROZYCKA, J., GORSKI, M., STANIAK, Z., GAJEWSKI, J., LIPINSKA, P., PASTUSZAK, A.

Institute of Sport

Introduction Assessing jump performance as measurements of the maximal power output and the height of jump on a force plate are a typical methods used in laboratory tests. Our recent research (Busko et al., 2012) did not show significant differences in height of jump (both CMJ and SPJ) and in maximal power in CMJ among age groups of female volleyball players. Thus the aim of the present study was to identify age-related differences in the maximal power output and the height of jump measured in the counter-movement jump (CMJ) and the spike jump (SPJ) of youngsters, cadet, junior and senior male volleyball players. Methods Two hundred and forty elite male volleyball players took part in our study. The study group was comprised of youngsters (n=30), cadets (n=112), juniors (n=35) and seniors (n=63). Their body height were similar in all age groups, albeit significant differences in body weight were observed between youngsters vs juniors and seniors, and between cadets and seniors. Athletes performed two types of vertical jumps: counter-movement jump (CMJ) and spike jump (SPJ) on a force plate. Power output and height of jump were calculated from the registered ground reaction force. Differences among groups were assessed using analysis of variance (one way ANOVA) with post-hoc Scheffé test. Statistical significance was set at p<0.05. Results The relative maximal power output derived from CMJ was similar in all groups. The relative maximal power resulted from CMJ and jump height derived from CMJ and SPJ differed significantly between seniors and youngsters. An age-related difference was only observed in absolute power output in SPJ jump. Discussion Some authors observed significant differences between age groups in jump performance (Alegre et al., 2009), in turn our recent research (Busko et al., 2012) showed no substantial age-related differences

in height of jump (both CMJ and SPJ) and in maximal power output (CMJ). In our present study all groups of athletes demonstrated similar height of jump, as well as similar relative power output (both CMJ and SPJ), only the absolute maximal power (SPJ) differed among groups. However less relative power output (both CMJ and SPJ) was developed by youngster players in comparison to senior males. Finally, our research showed that age-related differences were only observed between all groups of male athletes in power output of SPJ. A CROSS-SECTIONAL INVESTIGATION OF THE AGE-RELATED DEVELOPMENT OF POWER EXERTION IN THE LOWER LIMB AMONG JAPANESE SPEED SKATERS

YUDA, J.1, YOKOZAWA, T.2, ONO, E.1

1: Japan Women's College of Physical Education, 2: Japan Institute of Sports Sciences

Introduction The skating velocity has been confirmed to be affected by the external power output of a skater, as well as air and ice resistances (van Ingen Schenau, 1982; van Ingen Schenau et al., 1987; de Koning et al., 1992). In addition, skaters can attain the skating speed by propulsive support leg extension under the crouched skating posture with a small knee and trunk angle. Therefore, the ability of power exertion in the lower limb is an important factor for speed skaters. This study identified the characteristics of the age-related development of power exertion in the lower limb among speed skaters. **Methods** In total, 118 skaters (67 men and 51 women) provided informed consent and served as the study subjects. The skaters participated in the 500-m race of domestic speed skating competition in Japan or a time trial. The skaters were divided into 6 groups based on their age for each sex. However, senior skaters (over 18 y old) were divided into 2 groups based on the average time of the 500-m race. The age and average time for each group (mean \pm SD) were as follows: MG1, 9.8 \pm 0.4 y, 58.48 \pm 12.36 s; MG2, 11.6 \pm 0.5 y, 49.34 \pm 6.54 s; MG3, 14.1 \pm 0.7 y, 43.26 \pm 4.11 s; MG4, 16.8 \pm 0.9 y, 39.04 \pm 1.24 s; MG5, 20.1 \pm 1.4 y, 38.03 \pm 0.96 s; MG6, 23.4 \pm 3.8 y, 36.18 \pm 0.56 s; WG1, 9.4 \pm 0.5 y, 66.68 \pm 20.96 s; WG2, 11.8 \pm 0.4 y, 49.87 \pm 4.47 s; WG3, 13.9 \pm 0.8 y, 45.89 \pm 3.10 s; WG4, 16.8 \pm 0.9 y, 42.90 \pm 1.30 s; WG5, 21.3 \pm 4.4 y, 41.60 \pm 1.26 s; and WG6, 24.0 \pm 3.9 y, 39.72 \pm 0.50 s. The skaters performed double- and single-leg skate jump tests on a floor that required maximal effort. The vertical ground reaction forces were determined with a force platform (500 Hz). **Results** In male skaters, the maximum vertical ground reaction force of double-leg gradually increased with growth; by contrast, that of a single-leg increased only slightly. On the other hand, in female skaters, the force of double-leg gradually increased with growth; however, no remarkable difference between groups was observed in that of a single-leg. **Discussion** The level of power exertion in the lower limbs of both male and female speed skaters increased gradually as a result of physical growth and development. However, the development of the power exertion ability under the single-leg condition was lower than that in the double-leg condition. EFFECT OF NEUROBIKE CYCLING ON EEG BRAIN ACTIVITY AND MATHEMATICAL PERFORMANCE: AN INTERVENTION STUDY

JOHN, A., HENZ, D., SCHÖLLHORN, W.I.

University of Mainz

Introduction The NeuroBike is an unstable system applied in sports therapy and sports training. The balance movement is similar to the cross-coat of the human due to the joint in the center of the bicycle frame. In the present study, we investigated effects of training on the NeuroBike on spontaneous EEG activity and on mathematical performance. **Methods** N = 36 young adults performed different trainings (NeuroBike, common bicycle, daily activity) for twenty minutes three times per week in a two-week intervention. Mathematical performance (algebra, geometry, arithmetics) was assessed before and after the intervention by a multiple-choice test on a PC. Spontaneous resting EEG was recorded by the international 10-20 system before, and after each training session at rest, and during the mathematical tests before and after the two-week intervention. Spectral power densities were calculated for the theta (4-7.5 Hz), alpha (8-13 Hz), alpha1 (8-10 Hz), alpha2 (10-13 Hz), beta1 (13-30 Hz), beta2 (13-15 Hz), beta3 (21-30 Hz) and gamma (30-70 Hz) band. **Results** Behavioural data show slightly reduced mathematical performance in geometry after the NeuroBike and common bicycle intervention in comparison to daily activity. Heart rate during training sessions revealed no significant difference, although in common cycling higher physical effort was reported. Mental effort in NeuroBike cycling was increased after the two week intervention while physical effort remained stable instead of changes in ordinary cycling. EEG data reveal increased temporal theta power, occipital theta, alpha and beta1 power and parietal beta power after the two week intervention without acute influence of NeuroBike cycling at rest. No changes in acute influence of NeuroBike training as a result of the two week intervention was observed. Repeated NeuroBike training lead to increased frontal power in all frequency bands and temporal theta and alpha power during algebra performance. **Discussion** Changes in EEG at unaffected rest after the two-week intervention indicate a positive effect of NeuroBike training on brain activity. In contrast, mathematical performance was associated a negative impact with cycling. Following the stability of acute influence on brain activity we suggest an independence of NeuroBike exercise repetition on the acute effect, which a subsequent long-term study may possibly verify. Our results demonstrate that training on the NeuroBike fosters a beneficial brain state for learning at resting state, but does not lead to an optimum brain state for active processing in mathematical problem solving. MUSCLE ACTIVITIES AND MECHANICAL PROPERTIES ON KNEE EXTENSOR MUSCLES UNDER ISOMETRIC CONDITION

TANAKA, S.1, IMAWAKA, T.2, YORIMITSU, I.2, DJORDJEVIC, S.3, TSUNODA, N.2

1: Kokushikan University (Tokyo, Japan), 2: Graduate of Sport System, Kokushikan University (Tokyo, Japan), 3: University of Primorska (Koper, Slovenia)

Introduction Recently, muscle contraction (MC) sensor is possible to evaluate the mechanical property during muscle contraction. It has been reported that muscle activity and MC signal was related to the elbow flexion force in isometric contraction. However, relationship between muscle activity and mechanical property of knee extensor muscle under isometric condition is not clear. Therefore, the purpose of this study was to investigate the relation of electrical activity and mechanical property under isometric contraction in knee extensor muscles. **Methods** Eighteen males (age: 24.7 \pm 5.0 yrs, Height: 174.3 \pm 7.5 cm, Weight: 69.4 \pm 11.7 kg) without disabilities to knee joint were participated in this study. The muscle torque (MT) of knee extension under isometric condition with knee angle of 80 degrees was meas-

ured using dynamometer (Biomedex co.). At the same time, the tension of muscle belly for vastus lateralis (VL), rectus femoris (RF) and vastus medialis (VM) as a mechanical properties (FMC) were measured by MC sensor (TMG-BMC co.). MC signal indicate the tension of muscle belly and tendon on contraction. The relative values to the each peak value of MT (%MT) and FMC (%FMC) were calculated in all the subjects. And also, the electrical activities of knee extensor muscle were measured by surface electromyography. In addition, it was integrated (iEMG). Results FMC of VL (2.75 ± 1.64 N) showed significantly highest values among the muscle groups (RF: 1.89 ± 0.81 N, VM: 1.59 ± 0.98 N). iEMG was closely related to the MT in all the muscles (RF: $r = 0.994$, VM: $r = 0.991$, VL: $r = 0.988$). And, significant correlation coefficients were obtained between iEMG and %FMC (RF: $r = 0.992$, VM: $r = 0.986$, VL: $r = 0.994$). Furthermore, high linearity and good dynamic properties were showed between %MF and %FMC of knee extensor muscle (RF: $r = 0.998$, VM: $r = 0.998$, VL: $r = 0.997$). Discussion In this study, MC signal of vastus lateralis, rectus femoris and vastus medialis muscles were strongly correlated to muscle torque and electrical activities under isometric condition. From these results, it was supported the previous studies for elbow flexor. Therefore, MC sensor may effective method to evaluate the mechanical function of the muscle. MUSCLE ACTIVITIES AND MECHANICAL PROPERTIES OF THIGH MUSCLE DURING ISOKINETIC KNEE EXTENSOR MUSCLE.

IMAWAKA, T.1, YORIMITSU, I.1, TANAKA, S.2, DJORDJEVICS, S.3, TSUNODA, N.1

•Institution: 1: Graduate school of Sport System, Kokushikan University (Tokyo, Japan) 2: Kokushikan University (Tokyo, Japan) 3: University of Primorska (Koper, Slovenia)

Introduction Different methods and techniques have been used to assess muscle contraction properties. Such as, recording for torque measurement, electromyography and MC sensor. In here, measurements with MC sensor on the biceps brachii during isometric contraction showed a linear correlation between the isometric force and MC signal amplitudes. However, muscle activities and mechanical properties using MC sensor in isokinetic contractions with knee extension exercise is not clear. Therefore, the purpose of this study was to investigate the relationship between muscle activities and mechanical properties of knee extensor muscle with isokinetic condition. Methods Eighteen males were participated in this study (Age : 24.7 ± 5.0 yrs, Height : 174.3 ± 7.5 cm, Weight : 69.4 ± 11.7 kg). The subjects were performed 30 times knee extension with isokinetic contractions. The muscle torque (MT) was measured using dynamometer (Biomedex co.). At the same time, activities of vastus lateralis (VL), vastus medialis (VM) and rectus femoris (RF) were measured by surface electromyography. Integrated electromyography was used as a muscles activities (iEMG). Tension of knee extensor muscles as a mechanical properties (FMC) were measured by MC sensor methods (TMG-BMC co.). Decrease rate of MT (%MT), iEMG (%iEMG) and FMC (%FMC) were normalized to the peak value during 30 times isokinetic contractions with knee extension. Results MF and FMC were decreased with number of isokinetic knee extension in all the muscles. On the other hands, iEMG of VL and VM were showed almost same values during knee extension exercise. Whereas, its value of RF was significant increase with number of contractions during knee extension. Correlation coefficient was obtained between %iEMG of VM and %MT during 30times isokinetic contractions with knee extension. In addition, %iEMG were related to %FMC of RF and VL. %FMC in the all muscles were closely related to %MF. Discussion In this study, a linear correlation between %MT and %FMC were observed in knee extensor muscles. From these results, it was considered that the muscle torque were reflected to tension of knee extensor muscles as a mechanical properties. EFFECT OF REPEATED SHORT-DISTANCE SPRINTS IN ADDITION TO A STANDARDIZED WARM-UP ROUTINE ON SWING VELOCITY

NAKAMURA, M.1, OKAMOTO, C.1, TSUCHIYA, T.1, TANAKA, M.1, TAKEUCHI, K.2, TSUKUDA, F.2, HOJO, T.1, NAKAMURA, Y.1

1: Doshisha University (Kyoto, Japan), 2: Biwako Seikei sports college (Shiga, Japan)

Introduction: In baseball and softball, an increase in bat swing velocity could be beneficial for improving batting performance. Therefore, baseball players have attempted to increase their bat swing velocity through different warm-up routines. For example, baseball players often perform repeated short-distance sprints in addition to a standardized warm-up routine. Although a few previous studies have examined the effect of using a weighted bat on bat swing velocity (Otsuji T. et al. 2002, Wilson JM. et al. 2012), the effect of repeated short-distance sprints on bat swing velocity remains unclear. Purpose: The purpose of the present study was to investigate the effect of repeated short-distance sprints in addition to a standardized warm-up routine on bat swing velocity in university baseball players. Methods: Three-dimensional batting biomechanics (Mac3D System, Motion Analysis) were measured before (PRE) and after (POST) repeated short-distance sprints in eight male university students. The repeated short-distance sprints comprised ten 30-m sprints with approximately 1 min of active rest between each sprint. In both the PRE and POST conditions, the batter performed 10 swings as fast as possible. The maximum bat velocity and five trials with the highest swing velocity for each PRE and POST period were identified, and the maximum bat velocity and average value of five trials were used for statistical analysis. Significant differences between PRE and POST measurements were determined using the paired t-test. Results and Discussion: There were no significant differences in the maximum and average bat swing velocity (maximum PRE: 123.6 ± 7.8 km/h, maximum POST: 123.2 ± 7.4 km/h, $P = 0.76$; average PRE: 122.6 ± 7.7 km/h, average POST: 122.0 ± 7.2 km/h, $P = 0.30$). An increase in bat swing velocity would provide the batter with more time to see a pitched ball (increased decision time), enabling the batter to make a successful decision concerning whether to swing at a pitched ball (Szymanski DJ et al. 2009). The results of the present study suggested that repeated short-distance sprints in addition to a standardized warm-up routine did not increase batting performance in university baseball players. MORPHOLOGICAL COMPARISON OF UPPER LIMBS OF RUSSIAN JUNIOR JUDOKAS IN VARIOUS WEIGHT CATEGORIES

ELIPKHANOV, S., NEMTSEV, O., NEMTSEVA, N., DOLUDENKO, E.

Adyghe State University

ASU (Maykop, Russia) Introduction Differences in morphological characteristics of judokas in various weight categories may serve as objective data to tailor their competitive activity and training. However, so far there have been very few studies of this kind. It was only

found that heavyweight competitors were taller and had more body fat (Krstulovic et al., 2006; Franchini et al., 2011 et al.). Therefore, the aim of this study was to compare the morphological characteristics of upper limbs of Russian junior judokas belonging to various weight classes. Methods Forty-four judokas (9 first rank athletes, 30 Candidate Masters of Sports and 5 Masters of Sports of Russia) took part in the study. The morphological characteristics of 27 judokas of lighter weight categories (under 60 and 66 kg) and 17 judokas of heavier weight categories (under 73 and 81 kg) were compared. The following measurements were taken: length of upper arm, forearm and hand, arm (relaxed) and forearm girth, hand breadth, triceps and forearm skinfold thickness. Weight-to-height ratio and upper arm, forearm and hand lengths relative to height were calculated. One-way analysis of variance was used to examine the statistical differences of data. Results It was found that heavier judokas have significantly larger lengths of forearms and hands, hand breadth, arm and forearm girths, and triceps skinfold thicknesses ($p<0.05-0.001$). Non-significant differences in upper arm lengths and forearm skinfold thicknesses were found between the two groups ($p>0.05$). Judokas of heavier weight categories had larger height and weight-to-height ratio ($p<0.01-0.001$). Non-significant differences in upper arm and hand lengths relative to height were found between the investigated groups ($p>0.05$). However, forearm-to-height length ratio was significantly larger for heavier judokas ($p<0.05$). Discussion Most of the differences in the lengths of body segments of judokas belonging to various weight classes may be explained by their difference in height. However, significantly larger forearm-to-height length ratio in heavier judokas has shown that there are big differences in proportions of upper limb segments between the compared groups. This may be the reason for the specific techniques of their judo grips and counterwork. Significantly larger weight-to-height ratio in judokas of heavier weight categories may determine their 'force' style, but also may be due to larger body fat percentage which is partly confirmed by significantly larger triceps skinfold thickness. DIFFERENCES IN MUSCULAR ACTIVATION PATTERNS DURING ELASTIC AND WEIGHT RESISTANCE TRAINING

RONCA, F., SPENDIFF, O., BROUNER, J., SWANN, N.

Kingston University

Introduction Elastic resistance training is becoming increasingly common among athletes of varying levels, however there is little understanding about muscle activation patterns elicited by elastic training and how they might differ to weight training. The aim of the current study was to analyse patterns of muscular activation elicited by training with elastic versus weight resistance. Methods Seventeen recreationally active males, performed four exercises: bicep curl, lateral raise, leg extension and standing leg curl. Electromyography (EMG) was recorded for the biceps brachii (BB), tricep brachii (TB), deltoid medialis (DM), trapezius descendens (TD), vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF), bicep femoris (BF) and gastrocnemius lateralis (GL) using wireless electrodes and was normalised to maximal voluntary contraction (MVC). Joint angle data was captured for each relevant joint through 3D motion analysis. EMG and 3D data were integrated and the average muscular activation was recorded for every 20° of range of motion (ROM) for three repetitions of each muscle, per condition, per exercise. Exercises were executed at 1rads⁻¹; each exercise was performed with one elastic tube at three different initial lengths: T0 (0% stretch), T10 and T20 (10% and 20% reduction in initial tube length respectively) and a weight of equivalent resistance to the tube (W) as determined by the tube manufacturer. Data for each variable was analysed by within subject repeated measures ANOVA. Results Elastic training elicited lower ($p<.05$) muscular activation than W at beginning stages of the movement of the bicep curl (BB), leg curl (BF, GL) and leg extension (BF); and higher ($p<.05$) activation at final stages of ROM of the bicep curl (BB, TB), lateral raise (DM, TD, BB) and leg extension (VL). T0 elicited lower ($p<.05$) activation than T20 at varying stages of the bicep curl (BB, TB), lateral raise (DM, TD, BB) and leg extension (RF, VM, VL, BF). Discussion Elastic resistance elicited lower activation than weight resistance at initial stages of movement, and higher activation at final stages of the movement where weight resistance generally showed a drop in muscular activation. Auxiliary muscles were generally more active under elastic resistance, suggesting that elastic resistance may be a more appropriate method for proprioceptive training. Antagonist muscle activation response varied between exercises. In conclusion, elastic training provoked opposing muscular activation patterns to weight training, where as one increased the other decreased, indicating that the two training methods may elicit muscular adaptations at differing muscle lengths, and may be effectively used as complementary training methods. A STUDY OF THE STRUCTURE OF THE COMPETITIVE ROUTINES ON HORIZONTAL BAR

ANGELOV, V., KJUCHUKOV, I., ANDREEV, P., YANEV, I.

National Sports Academy

INTRODUCTION The development of the exercises on horizontal bar is in constant dynamics. We consider that the study of the structure of the competitive routines will help the specialists to construct more effective and more virtuosic routines that will be executed safely and steadily. The aim of this study is to establish the current tendencies regarding the structure of the competitive routines on horizontal bar. In order to achieve this aim, some groups of tasks were determined. METHODS The research is conducted on the basis of video footage containing performances on a horizontal bar during the European games in Baku and The World Championship in Glasgow in 2015. We researched the best horizontal bar routines that were executed by 24 gymnasts that had competed in the all-round. RESULTS The survey includes data collection about compositional and technical structure of the routines. The compositional structure was analyzed on the basis of the data collection concerning the relation between the main and additional structural groups exercise, their motor characteristics and difficulty. The technical structure was analyzed on the basis of the collected data about the safety and stability of the routines' executions and biomechanical analysis of the exercises with technical errors. DISCUSSION The research of the compositional structure of the routines helped us to find the average number of exercises in one routine (31 and 26) and the number of the different kinds of exercises included in the routines from both competitions (55). The study proved that from all determined structural groups, the biggest part have the giant swings backward elements (36%), "in bar" elements (14-16%) and flight elements (10-12%). According to the difficulty, the most widely used exercises are from groups A and D. The analysis of the technical structure of the routines has proved that the safety and the stability of the researched routines from both competitions are about 88%. There are three interruptions from 24 executed routines. The exercises with technical errors that caused interruptions are from groups C, D and E. The biomechanical analysis of these exercises enables us to determine the causes for these errors. REFERENCES: Angelov V. (2015). BIOMECHANICAL CHARACTERISTICS OF THE RADIUS OF CURVATURE ON A NON-MOTORIZED CURVED TREADMILL WALKING AND RUNNING

KIM, S.Y., HYEONG, J.H., ROH, J.R., KWON, O.H.

Korea Institute of Industrial Technology

INTRODUCTION: Non-motorized treadmill with curved surface which enables indoor walking and running exercise without any electricity is a notable alternative for traditional motorized treadmill by its self-adjusting speed controls. Since running surface is concave on the curved treadmill, different physical benefits such as increased oxygen consumption at slow speed, decreased reaction force at initial contact are assumed to compare with flat treadmill. **Purpose:** This investigation was undertaken to examine the biomechanical responses during walking and running on a Non-Motorized Curved Treadmill (NMCT). **METHODS:** In this study, three different radius of curvature (2500mm, 3000mm, 3500mm) of the NMCT were used to treadmill walking and running according to the three different speeds(70, 110, 170 step/min), and the speeds were controlled by cadence. Subjects walked for two minutes with breaks between trials of speed and curvature to prevent fatigue. Twenty-seven retroreflective markers affixed to the full body were used to record three-dimensional kinematics (60Hz, Osprey, Motion Analysis Corp., USA) on the three different curvature of the NMCT with three different speeds. **RESULTS:** With the speed increasing, step length was increased and step width was decreased on the all three different radius of curvature. Initial contact position on the treadmill belt has moved backward at lesser curvature. But the step width and deviation of center of body mass in the Anterior-Posterior direction were increased at the decreased radius of curvature, which mean the stability of walking and running on the NMCT was decreased. **CONCLUSION:** Consequently, the curvature needs larger radius to make stable walking and running, on the other hand, it needs lesser radius to walk and run easily on the NMCT. **REFERENCES:** 1. RUNNING AT DIFFERENT SPEEDS, THE ROLE OF THE INTACT AND PROSTHETIC LIMBS FOR TRANS-TIBIAL AMPUTEES

STRIKE, S.

University of Roehampton

Introduction Running speed is determined by the step length and cadence, and up to speeds of 7m/s the dominant strategy to run faster by using the ankle muscles to push harder on the ground increasing step length (Dorn et al 2012). Trans-tibial prostheses have a passive ankle, which means that they cannot generate more power than they absorb. It is not known how this responds to increasing speed and how the peak vertical ground reaction force (vGRF), cadence and step length change. Thus the aim was to determine how the intact (I) and prosthetic (P) side of people with a trans-tibial amputation respond to change speeds. It was hypothesised that the P side would not increase peak force or step length when increasing speed while the I limb would increase both force and step length. Finally we hypothesised that with increasing speed the step length and peak vGRF would become asymmetrical. Methods Six male recreationally physically active trans-tibial amputees (mean age: 39.5years, height:1.81m and mass 80.93kg) participated in the research. All wore the Endolite Blade XT prosthesis and were free from injury and residual limb pain or skin issues. Amputees were asked to run at 3 self-selected speeds, comfortable jog (SS), 70% of that speed (Slow) and 130% of that speed (Fast) across a forceplate (1000Hz) while their motion was recorded using a synchronised VICON motion caption system (100Hz). Fast and Slow speeds were individually calculated from the SS and were controlled within 5% by speed gates. Five successful trials (clean foot contact on the forceplate, within the speed limit) per leg with were recorded. The effect of running speed on cadence and on each of the I and P step length, and peak vGRF was determined using repeated-measures ANOVA. Significance was set at $P<0.05$. Results Speed had an effect on all variables except the peak vGRF on the P side between SS and Fast. I step length (Slow: 0.83 ± 0.12 ; SS 1.12 ± 0.14 ; Fast 1.29 ± 0.11 m) and P Step length (Slow 0.83 ± 0.12 ; SS 1.09 ± 0.14 ; Fast 1.30 ± 0.13 m) also proved to be symmetrical at each speed. The peak vGRF tended to become more asymmetrical as the speed increased (I Slow 21.81 ± 4.19 ; SS 24.81 ± 3.86 ; Fast 26.63 ± 3.19 ; P Slow: 18.88 ± 2.17 ; SS 21.16 ± 1.9 ; Fast 22.90 ± 2.58 N/kg). Discussion Amputees were able to increase speed through altering the cadence and the step length on both sides. We had anticipated that the restrictions of the passive ankle would lead to a change only in cadence and I step length, as the ankle on the I side can create a larger force in order to propel the leg further as it swings but the P side step length is restricted by the inability to generate a large peak force to propel it. Although the P peak vGRF did not significantly increase from SS to Fast, the step length increased, suggesting that the length is modulated by other factors. This 'topping-out' of the peak vGRF for amputees is likely due to the passive nature of the prosthesis. References Dorn TW, Schache AG, Pandy MG (2012) J Exp Biol 215 (Pt 11):1944-56

BIOMECHANICAL COMPARISON OF VERTICAL JUMP PERFORMANCE DURING TAKE-OFF PHASE BETWEEN LAND AND WATER ENVIRONMENTS

CHEN, W.C.

Graduate Institution of sports equipment technology

Introduction Aquatic-based plyometric training has become an alternative to exercise training on land (Stemm, Jacobson, 2007) because of the same improvement and less impact force through buoyancy (Donoghue, Shimojo, and Takagi, 2011). However, there is no further observation the jump performance under water so far. Therefore, the purpose of this study was to compare the ground reaction forces (GRF) and knee and ankle angle velocities during takeoff of counter movement jump (CMJ) between on land or in pool of water. Methods 5 college men were recruited in this study (average height was 172.35 ± 3.75 cm, the average body weight (BW) on land was 65.14 ± 3.85 kg, and the aquatic BW was 46.30 ± 3.20 kg). Then participants were asked to perform counter movement jumps (CMJ) on land or in water randomly on an AMTI waterproof force measurement device. The standing immersion depth of the navel level (± 3 cm) was set in this study. We recorded three successful CMJ in land and aquatic based condition with sampling frequency of 1000 Hz and analyzed the peak GRF during takeoff of each jump. The force data were normalized by the body weight in the condition. Besides, the jump performances were captured by commercial camera with a waterproof case with 30 Hz sampling rate. Knee and ankle angle velocities during propulsive phase of jumping were calculated through Siliconcoach motion analysis software. A paired t test was used to exam all parameters of jumps between land and water conditions. Results The peak GRFs of CMJ are 1.78 ± 0.20 BW on land and 2.68 ± 0.16 BW in water as well as those of rate of force development are respectively 2.19 ± 0.09 BW/s and 3.62 ± 0.07 BW/s. Both force parameters in aquatic condition are significantly higher than those on land. While, knee angle velocities of 195.63 ± 27.93 , 248.89 ± 39.90 degree/s were produced on land and in water, respectively, ankle values of 138.62 ± 12.51 , 174.46 ± 80.58 degree/s. Discussion The BW in water is approximate 71% on land because of the buoyancy which can effectively decrease the landing force that may serve as a reduction in

potential muscle damage. However, the aquatic GRFs and rate of force development during takeoff are higher of CMJ by 1.51 and 1.62 times respectively. Participants need to generate more force production with quick lower-extremity angle velocities with more to overcome water drag resistance than the gravity on land. Consequently, this finding suggests that aquatic jump is an alternative to exercise training on land. References Donoghue OA., Shimojo H, Takagi H. (2011). Sports Health, 3(3), 303-309. ACCURACY OF THREE-DIMENSIONAL MEASUREMENT FOR HIP, KNEE, AND ANKLE JOINT ANGLES DURING WALKING AND RUNNING BY USING INERTIAL MEASUREMENT UNIT

KOSAKA, M.1, HASHIZUME, S.2, YANAGIYA, T.1

1:Juntendo University (Chiba, Japan), 2: AIST (Tokyo, Japan)

Introduction Inertial measurement unit (IMU) constructed by gyroscope, accelerometer and magnetometer was used to measure the joint angles of lower extremity in three-dimensions (3D) during walking (Favre et al., 2008). Cooper et al. (2009) reported that the accuracy of the IMU for the measurement of the joint angles were decrease with increase in walking speed. This suggests that the accuracy of IMU may be lower for running than for walking. To apply the IMU for running, the accuracy of IMU should be compared to walking and running. The purpose of this study was to examine the difference in the accuracy of IMU for measurement of the joint angles of lower extremity in 3D between walking and running. Methods Fourteen healthy young adult males participated in this study. IMUs (Myomotion, Noraxon) and retro-reflective markers were attached to the pelvis and the right lower extremity. Optical motion capture system (OMC) (Vicon MX, Oxford) as a reference system was used to measure the joint angles of lower extremity in 3D. IMU and OMC were electrically synchronized and recorded data at 100 Hz. The subjects performed to walk (1.67 m/s) and run (3.33 m/s) on treadmill. Root-Mean-Squared (RMS) differences between the joint angles determined by using IMU and OMC were calculated to evaluate the accuracy of IMU. Two-way ANOVA with repeated measures was conducted for testing the effects of types of locomotion and directions of joint angles on RMS difference. Post-hoc test with Bonferroni correction was conducted to test the difference in RMS difference between walking and running in the each joint angle. Results Mean RMS difference of the hip joint angles for walking (FE: flexion-extension, IER: in-external rotation and ABD: ab-adduction) were 3.7°, 3.8° and 2.8° for FE, IER and ABD, respectively. The corresponding values for running were 5.4°, 5.1° and 4.4°. Mean RMS of the knee joint angles (FE, ABD and IER) were 3.4°, 2.8°, 3.2° in walking and 7.1°, 4.4°, 4.6° in running. Mean RMS of ankle joint angles (plantar-dorsi flexion, in-eversion and IER) were 7.8°, 4.1°, 4.2° in walking and 11.8°, 6.6°, 5.7° in running. Mean RMS of hip, knee, ankle joint angles in running were significantly higher than mean RMS in walking and there were no interaction. Discussion Mean RMS differences of the each joint angles for running was larger by 1.3-4.0° than that for walking whereas the direction of joint angles did not influence the mean RMS differences. These results indicate that the accuracy of IMU for the measurement of the joint angles of lower extremity in 3D is lower for running than for walking. References Favre J. et al. HEAD IMPACT MECHANISMS DURING PRACTICE FOR SOCCER OF JUNIOR ATHLETES

OSULLIVAN, D.

PUSAN NATIONAL UNIVERSITY

Introduction Since the high number of deaths (suicides) and debilitating head injuries in American Football there has been a lot of attention both by the media and by researchers for head injuries in sport. However, soccer is reported to be responsible for the largest number of head impacts and highest concussion rates among females (Gessel et al., 2007). Only recently the technology to measure head impact mechanisms during practice and competition is available and so there is a dearth of data regarding the magnitudes and frequency of head impacts in soccer for all genders and levels. Therefore the purpose of this study was to measure the head impact characteristics of junior boys during soccer practice. Methods Using the xPatch (Biosystems Inc.) head impact data (peak linear acceleration (PLA), peak rotational acceleration (PRA), peak rotational velocity (PRV) and Head injury Criterion (HIC) 15ms) were collected over ten training sessions. Ten junior boys aged between 8 and 12 years of age participated after their parents/ guardians signed the University Hospital approved IRB consent form. Data from the sensor was then backed up on the Biosystems cloud and their proprietary software Impact Management System software was used to output the impact severity related variables. Non-parametric Krushall-Wallis tests were used to investigate the differences in the sessions and among the participants. Results During the ten sessions, there were a total of 501 impacts recorded, averaging out at 90 impacts per 100 minutes. The averages and standard deviations for PLA, PRA, PRV and HIC were $17.8 \pm 10.3\text{g}$, $3168 \pm 2442\text{deg/s}^2$, $16.1 \pm 10.6\text{deg/s}$, 11.4 ± 34.2 . The most impacts were located at the back of the head (45.5%), followed by the side (33.7%), front (19.9%) and top (0.9%). According to the PLA guidelines by King (2014) 96.2% were classified as low severity (10-39g), 3.3% medium severity (40-69g), and 0.4% as high severity (<70g). Discussion With the exception of a few impacts (2 impacts) the magnitudes recorded in this study were not classified as a high severity. However, because of the high frequency of head impacts in soccer, it is important for those participating and their medical support staff to be aware of the risks associated with repetitive impacts. Future research is needed to maintain a longitudinal design to assess the effects of repetitive low impacts. References Gessel LM, Fuelds SK, Collins C, Dick RW, Comstock, RD (2007). SHOE MIDSOLE HARDNESS EFFECTS ON PLANTAR FORCE DURING HEEL-TOE RUNNING

HORIGUCHI, Y., TSUJI, H., YANAGIYA, T.

Juntendo University

Introduction The shoe midsole hardness is one of factors, which determine the function of shoes. It was made clear that vertical ground reaction force during stance phase was not influenced by the shoe midsole hardness. However, vertical ground reaction force measured by force platform couldn't explain distribution of plantar force. Thus the effect of shoe midsole hardness on the plantar force in each foot regions during running, for example plantar force in heel region during heel contact has not clear. Therefore, the purpose of present study was to investigate the effect of shoe midsole hardness on the plantar force in each foot region during running. Methods Five males without any deficit in their lower limbs served as subjects. Their mean age, height and body weight were 21.8 ± 3.34 yrs, 1.69 ± 0.02 m and 58.0 ± 2.75 kg, respectively. They have three running trial on the treadmill for one minute wearing 3 different hardness condition shoes, respectively. The shoe condition divided only by difference in their midsole hardness: SOFT, MEDIUM and HARD (hardness equal to 48°, 65° and 71°, respectively). Plantar force was measured by in shoe pressure measurement system (Pedar-X, Novell), comprising 99 capaci-

tive sensors. After data collection, we re-construct 99 sensors into 6 regions. Peak pressure, Peak resultant force were evaluated over the six plantar regions. Lower limb motion was captured from right side with video camera. Time-spatial parameters and Kinematic parameters of lower limb during stance phase were measured from the movie. One-way ANOVA with repeated measures used to determine if there were any differences in various variables from the use of different midsole hardness for running. All significant effects ($p < 0.05$) were followed by Tukey post hoc tests. Results No significant difference was seen among any variables and areas both in peak pressure and peak resultant force. Contrary, significant differences were observed both in the ankle joint angles and ankle joint angular velocities at 60, 70, and 80 % of stance phase, where it apt to be a dorsiflex position and lower in plantar flex velocity in the SOFT condition. Discussion Main results of present study were that significant differences in ankle joint angle and ankle joint angular velocity at 60, 70, and 80%stance phase, although no significant differences was seen in plantar pressure force and kinematic parameters in hip and knee joint. These results lead to the speculation that softer midsole may delay plantar flexion at the latter part of stance phase. Then, coaches and shoe distributor should take these results into consideration, because too softer running shoe midsole may not only train lower limb muscles but also disturb running form of the athletes. THE DIFFERENCE IN THE IMPACT OF THE HEAD DURING USHIRO-UKEMI AND UKEMI OF OSOTOGARI IN JUDO

YOSHIDA, T., HIROSE, N., YANAGIYA, T.

Juntendo University

Introduction Budo had become a compulsory subject in a course of study of Japanese junior high school in 2014. Therefore, most of junior high school students have a possibility to learn judo in physical education class since then. It is very magnificent for us, Japanese people, to experience traditional Budo. On the other hand, we can say that the population of beginner has increased because of its changes in compulsorization. Specifically, external head injury during judo is focusing. Therefore, the purpose of this study was to identify the maximal angular velocity(AV) and angular acceleration(AA) acted on head during Ushiro-ukemi(UU), Yoko-ukemi(YU), and ukemi for Ukemi of Osotogari(OU). It might be very important knowledge for practicing safely in a coaching scene. Methods Six collegiate judo wrestlers, who experienced judo over ten years served as subjects. Subjects did UU and YU. Moreover, they did ukemi after there were thrown with OU. Four retro-reflective markers were put on the subject's head surrounding during the experiment. The coordinate values were measured using 3D motion capture system (Vicon MX,Oxford). A coordinate system of a head was defined from the marker loaded on a head. And the AV and an AA were calculated. The maximum of an AV and the AA was presumed as the impact, which acts on a head. Results Maximum resultant AV during UU, YU, and OU were 347 ± 80.3 deg/s, 318 ± 29.9 deg/s, and 394 ± 82.3 deg/s respectively. Significant difference was seen among maximum velocities during UU and YU. And No significant difference was seen between YO and OU. Then, maximum resultant AA were. 5011 ± 983.3 deg/s², 7028 ± 2324.6 deg/s², and 7990 ± 3349.8 deg/s². Significant difference was seen between UU and YU. And No significant difference was seen between YO and OU. Discussion AV during OU indicated higher value compared with UU, though angular velocities didn't differ among UU and OU. Hitosugi et al (2014) buried accelerometer in dummy doll's head and reported the higher acceleration values during ukemi compared with the acceleration of present study. Therefore, it can be said that the originality of present study was to measure acceleration of head during ukemi in vivo, though the reported values were different from the reported values in present studies. As a result of this study, the acceleration during OU was significantly higher value compared with UU. In the course of study of in physical education in Japanese junior high school, OU was acquired immediately after UU. However, the result of present study indicate that osotogari should be taught after students acquire YU because of avoiding heavy head injure caused by OU. References Hitosugi, M et al (2014). Biomedical Research, 35(5), 339-344. Contact taira6664@gmail.com

SHEAR WAVE ELASTOGRAPHY OF MUSCLE AND TENDON BEFORE AND AFTER DYNAMIC STRETCHING: A PILOT STUDY.

PAMBORIS, G., NOORKOIV, M., MOHAGHEGHI, A., BALTZOPoulos, V.

Liverpool John Moores University

Introduction Shear wave ultrasound elastography (SWE) allows shear wave speed, which is related to stiffness, to be measured in vivo in individual muscles and tendons. SWE measurements might provide reliable material property measurements by aligning the transducer imaging plane with the muscle fibre orientation (Miyamoto et al., 2015, Eby et al., 2015). Our aim was to evaluate the material properties, specifically stiffness, as quantified based on shear wave speed in the medial gastrocnemius muscle (MGM) and Achilles tendon before and after an acute bout of dynamic stretching (DS). Methods A convenient sample of 6 persons volunteered for this study. The shear wave speed of the MGM belly and Achilles tendon were measured using the Aixplorer® ultrasound shear wave elastography (SuperSonic Imagine, France) before (PRE) and immediately after (POST) a DS protocol. Elastograms were taken with the participant lying prone and the ankle fixed at 10 degrees of dorsiflexion on a Cybex NORM dynamometer (Cybex International Inc., UK). The ultrasound probe (5-cm width) was applied very lightly with generous amount of contact gel, held in parallel with the MGM fascicles or Achilles tendon line of action and kept still for 10 s for the optimal acquisition of elastography images. Shear wave speed was measured as the average velocity +/- SD of the selected region of interest. The probe position was marked on the skin so that it was identical during the PRE and POST measurements. A standardised published DS protocol was adopted (Holt et al., 2008). Participants were instructed to perform 3 sets of 20 repetitions of active dorsi- and plantar flexion of both ankle joints through the full range of motion to a rhythm of 80 beats per minute provided by a metronome. Results A trend for an increase in MGM shear wave speed from PRE (6.80 m/s) to POST (7.25 m/s) was found (6.62%). The effect of DS on tendon shear wave speed was minor (1.54%; 9.08 m/s vs 9.22 m/s, respectively). Discussion A trend for a larger increase in shear wave speed in the muscle as compared to the tendon suggests that the effect of DS on tissue stiffness might be greater in muscle than in tendon. This pilot study demonstrates the potential of SWE as a non-invasive tool for investigating mechanisms of altered muscle properties after an intervention. KINETIC ANALYSIS OF PELVIS HORIZONTAL ROTATION OF ANGLED INSTEP KICKING IN SOCCER

INOUE, K., NUNOME, H.

Yamagata University

Introduction Previous study illustrated that matured instep kick included appreciable pelvis counter-clockwise rotation and that motion was induced by torques mainly due to ground reaction force (Inoue et al., 2014). However, mechanical factors that induce the pelvis rotation have not been revealed when players kick the ball to varied angles. This study aimed, therefore, to clarify the kinetic aspects of the pelvis rotation when players kick the ball towards angled directions. **Methods** Nine male soccer players performed maximum instep kicks towards three angled directions (15, 45 and 75 deg.). Their motions and ground reaction forces were recorded by a motion capture system at 500 Hz. Angular velocity and torque vectors regarding the support leg and the pelvis were calculated, and then the components that induce the pelvis rotation on the horizontal plane were extracted. **Results** An increase of the angle of kicking direction led to a significant ($p<0.05$) increase of the range of the pelvis rotation. With increasing the kicking angle, the higher hip joint torques of the support leg were observed. The angular impulses due to the hip joint torques were systematically and significantly ($p<0.05$) increased with an increase of kicking direction angle. The ranges of foot segment rotation (ROM) of the support leg were also systematically emphasized with an increase of the kicking direction angle while the torques for the foot rotation were small to be negligible in all the kicking directions. **Discussion** Scurr & Hall (2009) reported that soccer players displayed a greater pelvic rotation when using a wider approach angle. Levanon & Dapena (1998) argued that the pelvic rotation has a role to face the anterior half of the thigh (kicking leg side) onto the target direction. In this study, we succeeded in illustrating how the kinetic background changes when players kick the ball to angled directions. Inoue et al. (2014) already demonstrated that the interaction torque due to ground reaction force is the main drive in producing the pelvis rotation in normal straight instep kicking. We accumulated additional knowledge about the emphasized pelvis rotation when the ball was kicked to angled directions. The pelvis rotation was emphasized in response to the increased kicking angles. The hip joint torque (angular impulse) of the support leg was the kinetic factor systematically corresponded to the change of kicking directions. Thus, it can be assumed that the hip joint torque of the support leg is responsible for the increased pelvic rotations. Likewise, we observed the foot rotation was increased with an increase of the kicking angles. However, this motion was not accompanied by the action of the torque. Hence, it is most likely that the foot rotation is passively induced by some other factors such as partial friction of the floor acting on the foot segment. **References** Inoue K et al. (2014). RELATIONSHIP MAXIMAL AND EXPLOSIVE POWER TO PERFORMANCE OF MOTOR ACTIONS IN WEIGHTLIFTING

SIVOKHIN, I., FYODOROV, A., TAPSIR, M.

Kostanay State Pedagogical Institute

Introduction Identification of the most informative indicators of special physical fitness of athletes, as well as the assessment of their impact on the realizable efficiency of motor actions allows to obtain objective data for the development of more effective models of training and improvement of quality control by correcting the direction, structure and content of the training sessions. The purpose of research – to investigate the relationship of maximal and explosive power and performance of motor actions in weightlifting. **Methods** The study took part lifters of high qualification, aged 20-23 years (n=10). To determine the explosive power, which was estimated by the duration of the flight phase in the jumping tests, we use tensometric platform. Jumping carried out with a stop and with fast switching in the legs by bending at the extension. Jumps were performed with a barbell on your shoulders and weighing 50 and 100 kg and without complications. To determine the maximum strength applied squats on his shoulders with a maximum weight. Using test determined the maximum result in the snatch. **Results** The result in the snatch is a high degree of relationship with maximum strength ($r=0.85$). In addition to the high significance of the maximum strength to result in the snatch, an essential feature is the explosive power. Analysis of the relationship results in the snatch and jumping tests indicate that the greatest values coefficients of correlation are the results of such tests, like jumping up without burdening with fast switching in the muscles of the lower extremities with inferior mode to overcoming ($r=0.80$). Through the use of regression analysis of the parameters studied found that with an increase in the squat result (the maximum strength) of 10 kg in the snatch result increases by an average of 5.2 kg, and the increase of the flight phase jump time 10 ms increases to result in the snatch 18.3 kg. **Discussion / Conclusion** It is found that the tightness of relationship of results in the snatch, squats and squat jumps, at their joint effect is increased ($r=0.87$), and determines the result to sports 76.0%, and 50.0% is necessary to share the maximum power while the share of explosive power of 26.0%. Results in jumping to the stop and fast switching leg from bending at the extension at their joint effect, a high degree of correlation with the result in snatch ($r=0.85$) and its variation is determined at 72.0%. The share of jumps with a stop there are only 7.0%, while the share of jumps with fast switching in the muscles necessary to 65.0%. This confirms the importance of the use of stored elastic energy of the working muscles during rapid switching cycle «tension – reducing». **References** 1. Turkileri, E. HIP ROTATION AS A PREDISPOSING FACTOR OF THE SCREENING TESTS FOR ANTERIOR CRUCIATE LIGAMENT INJURY IN FEMALE ATHLETES

YASUDA, T.1,2, YOKOI, Y.2, OYANAGI, K.2, HAMAMOTO, K.2

Kobe City Medical Center General Hospital

Background Anterior cruciate ligament (ACL) injury occurs with a higher incidence in female athletes compared with males. No specific hip joint anatomy has been identified as a risk factor for ACL injury in females. Video analyses of non-contact ACL injuries indicate that the hip with an adducted and internally rotated femur and in little hip flexion creates knee valgus, tibial external rotation and forefoot pronation. Therefore, the knee injury could be the result of more proximal hip position. Understanding of proximal anatomical factors may be necessary to identify female athletes at high risk of ACL injury. However, no previous study has demonstrated the relationship of specific hip anatomy with ACL injuries or the risky landing pattern of ACL injuries in females. **Purpose** This study was conducted to clarify the association of hip rotations with knee valgus motion during ACL injury screening tasks that is the strong predictor of ACL injury. **Methods** The 6 measures of hip joint motion (flexion, extension, abduction, adduction, external rotation, and internal rotation) and the 2 measures of knee joint motion (flexion and extension) were collected with the standard procedure using a goniometer. Medial knee displacement in the frontal plane induced during the screening tests for ACL injury (drop vertical jump and single-leg squat tests) was evaluated as the representative of the knee valgus motion by the two dimensional video analysis method that has been shown to provide reliable evalua-

tions of frontal plane knee valgus motion. Results Knee valgus was induced in 24 and 22 of the 31 healthy female volunteers by drop vertical jump and single-leg squat tests, respectively. The knee valgus-positive females showed smaller range of hip external rotation than the negative ones, which was significantly associated with knee valgus during the screening tests. Hip internal rotation dominance (internal rotation range is greater than external one) was significantly related to knee valgus induced by each screening test. In contrast to the females, the male subjects showed lower rates of knee valgus induction by the screening tests, whereas there was no clear association between hip internal rotation dominance and the knee valgus induction. Discussion Female athletes with smaller external rotation of the hip by greater femoral anteversion may maintain the femoral head within the acetabular cavity through internal rotation of the hip. Such compensatory changes in the femoral internal rotation could lead to the knee valgus during the ACL injury screening tests. The present findings may indicate a predisposing role of hip rotation measurement in identification of females at risk for ACL injury.

LOWER LEG QUASI-STATIC STIFFNESS RELATED TO INJURY IN ELITE NETBALLERS

PICKERING RODRIGUEZ, E.C., WATSFORD, M.L., BOWER, R.G.

University of Technology Sydney

Introduction Relatively high lower-body stiffness has previously been related to an increased incidence of bony (Williams et al., 2004) and soft-tissue injuries (Watsford et al., 2010). The aim of this research was to determine if similar relationships exist between quasi-static stiffness of individual muscles and lower-body injury incidence in female netballers. Methods Four lower leg sites of an entire elite female netball team ($n=10$) were assessed for bilateral quasi-static stiffness using myometry (soleus, Achilles tendon, medial & lateral gastrocnemius). Any injury that occurred throughout the playing season was reported. Participants were first divided into injured and non-injured groups to compare the stiffness characteristics of each group in an injury segmentation analysis, and secondly divided into relatively stiff and relatively compliant groups to perform a stiffness segmentation analysis. Results The injured group exhibited significantly higher stiffness of the soleus ($p=0.037$) and Achilles tendon ($p=0.004$) compared to the non-injured group. The stiffness segmentation analysis revealed that odds of elite netballers sustaining a lower-body injury were 16 times higher with a relatively stiff medial gastrocnemius or soleus and 121 times higher with a relatively stiff Achilles tendon. Discussion The stiffness segmentation analysis suggested that athletes with relatively stiff medial gastrocnemii are at higher risk of injury however, the injury segmentation analysis did not reveal any significant results for this site. There were no significant differences in either analysis when considering the lateral gastrocnemius. These results suggest that the stiffness of the gastrocnemius complex does not contribute to lower-body injuries in netballers. A comparison of the injury incidence between the relatively stiff and relatively compliant groups revealed a higher injury incidence in participants exhibiting relatively stiff soleus and Achilles tendon complexes. Further, when comparing injured and non-injured groups, injured participants presented significantly higher stiffness of the soleus (22%) and Achilles tendon (35%). These results suggest that the stiffness of the ankle joint musculature is important when considering lower-body injury risk in elite netballers. This relationship is plausibly due to the high ankle joint loading during repetitive cutting and jumping movements performed in netball and has implications for strength and conditioning specialists when considering optimal preparation for netballers. CORRELATION BETWEEN THE CONFORT OF RUNNING SHOES AND ANTHROPOMETRIC CHARACTERISTICS OF FEET OF THE RUNNER'S

RIBEIRO, A.P.1,2, MAFFEI, M.1, COSTA, A.M.W.A.A.1, DINATO, R.C.2, YI, L.C.3

1 University of Santo Amaro, São Paulo, Brazil; 2 University of São Paulo, São Paulo, Brazil; 3 Federal University of São Pau

INTRODUCTION Running-related injuries are common and previous research has suggested that the magnitude of rearfoot pronation, plantar arch and shoes comfort are potential risk factors that can contribute to the development of these injuries [1,2]. However, the results on associations of the anthropometric feet with the comfort are still inconclusive regarding the running shoes. OBJECTIVE The objective of this study was to verify the correlation between the arch plantar and rearfoot angle with the comfort of the running shoe in runners. METHODS Twenty eight recreational runners were evaluated (age: 35.6 ± 9.0 years old; body weight: 72.1 ± 12.0 kg; height: 1.72 ± 0.09 cm). The runners underwent a running on the asphalt (40 m long track) and the shoes general comfort was acquired. After a running, the runner rated nine aspects of the shoe related to its perceived general comfort. Comfort Scale evaluated the perception of comfort for shoe evaluated (cushioning technology: EVA midsole)[1]. The static clinical measures were determined by footprint image on the podoscope to analyze plantar arch and the photogrammetry to measure the rearfoot angle [2]. Pearson correlation coefficient was applied ($p<0.05$). RESULTS AND DISCUSSION The shoes general comfort was not found to have a significant correlation with the plantar arch right (0.19 ± 0.07 cm: $r=0.10$, $p=0.640$) and left (0.20 ± 0.08 cm: $r=0.07$, $p=0.749$), but rearfoot angle had a moderate correlation with the general comfort aspects of shoe (6.5 ± 3.9 degrees right: $r=0.27$, $p=0.021$ and 4.2 ± 3.1 degrees left: $r=0.41$, $p=0.067$). DISCUSSION Studies demonstrated relationships between comfort perception of shoes (EVA and Adiprene cushioning) and dynamics biomechanical variables [1,3]. Interesting finding study was the association of shoes general comfort with the static rearfoot angle, but not with plantar arch, which can better target the purchase of the running shoes. This association was observed only for the EVA technology of the shoe. However, it was not possible to infer that the results found could be reproduced in other market technologies. CONCLUSIONS The results demonstrate significant relationships between the perception of comfort and rearfoot angle, but did not show with the plantar arch index for the running shoes investigated. Coaching

THE ACUTE EFFECTS OF POST-ACTIVATION POTENTIATION ON SHOT PUT PERFORMANCE IN FEMALE THROWERS

KONTOU, E., BERBERIDOU, F., MANTZOURANIS, N., PILIANIDIS, TH.

Democritus University of Thrace, Komotini, Greece

Introduction Limited research is available on the subsequent effects of the upper-body post-activation potentiation (PAP) on the competitive throwing activity in trained experts (Terzis et al., 2009). Therefore, the aim of this study was to evaluate the precise responses of two

upper-body PAP protocols on the shot put performance in experienced female throwers. Methods Ten (n=10) female collegiate throwers aged 18.9±1.2yrs participated in this study. In the initial screening, the throwers' personal best in Shot Put event was recorded and the 1RM in bench press lift was tested. The throwers performed in competitive conditions, in counterbalanced order in 2 testing trials with a 48-hour interval: 1st = 3 throws with a 10min rest (noPAP1) & 4 plyometric push-ups prior to the 3 throws (PAP1) and 2nd = 3 throws with a 10min rest (noPAP2) & 6s isometric push-ups prior to the 3 throws (PAP2). Their performance was carried out from the final release position with regulation weight implement. The Wilcoxon test and the Spearman's rho correlation were applied for the continuous data analysis. Results The statistical procedures revealed that the female throwers improved their performance by applying both PAP protocols: noPAP1=8.03m vs PAP1=8.15m, ($p=0.31$) & noPAP2=7.99m vs PAP2=8.13m, ($p=0.50$). In addition, the Spearman's analysis showed that the performance which was recorded by using the PAP1 was highly correlated with the throwers' personal best in shot put (0.76, $p<0.05$) but not with their bench press lift, (0.37, $p=0.30$). Similarly, the PAP2 protocol indicated high correlation with the female throwers' personal best in shot put (0.75, $p<0.05$) while no correlation was observed between the 6s isometric push-ups and their bench press lift, (0.49, $p=0.16$). Discussion The major finding of this study was that the plyometric push-ups seem to be more beneficial than the isometric push-ups or the no-treatment in the female shot put throwers. Thus, in conjunction with relevant bibliography (Bellar & Judge, 2011), this study confirms that the plyometric exercise highly influences the ballistic throwing performance. Furthermore, the direct correlation between both PAP protocols and the female throwers' personal best in shot put proves that, the higher the training level, the greater the effect of their upper-body PAP treatment. Conclusively, the present study confirms that the post-activation potentiation by applying the plyometric push-ups affects positively the competitive performance of expert female throwers. THE CHARACTERISTICS OF TURN RHYTHM PATTERNS IN THE MEN'S HAMMER THROW

HIROSE, K.1, OHYAMA, B.K.2, OGATA, M.2

University of Tsukuba

INTRODUCTION: The hammer throwers use turn movement to accelerate the hammer head. The duration time of turn is showed in previous researches (Gutiérrez et al., 2002; Isele and Nixdorf, 2010). Bartonietz (2000) noted that the turn rhythm is one of the important components for the hammer throw technique. However, turn rhythm patterns were seldom studied in previous researches. The aim of this study is to identify the specific rhythm pattern for each thrower. METHODS: We analyzed the duration time of turn for the 116 men's hammer throwers in the competitions. Their range of record was 49.11-85.20m and all throwers use 4 turns. These competitions included the Olympic Games, the World Championships, the Asian/European Championships and the Local Championships. We determined the duration time of turn from recorded movies and downloaded publicly available Internet broadcasts. Frame rates of analyzed movies were 30 to 100 fps. The duration time of turn is measured from instant of right foot takeoff from the ground in the first turn to instant of release in the last turn. Ward's method of the cluster analysis was used to classify turn rhythm patterns. RESULTS: Turn rhythm patterns were divided into 3 types: fast start (F-type, n=29), slow start (S-type, n=38), and middle (M-type, n=50). There were significant correlations between the total time of turn and the throwing record in all types. There were no significant differences in the throwing record between three types. The duration time at 1st turn of F-type was significantly shorter than M-type and S-type. The duration time at 4th turn of F-type was significantly longer than M-type and S-type. Total time of F-type was significantly shorter than M-type and S-type. DISCUSSION: Turn rhythm patterns are not the determinant for throwing record. In addition, decreasing the total time of turn leads to a longer throwing distance for all types. These results suggest that each turn rhythm pattern corresponds to different strategy to accelerate the hammer head and we can not suggest athletes/coaches should select what type of turn rhythm pattern. The duration time at 1st turn of F-type is shorter, but 4th turn is longer. In addition, F-type requires shorter total time to throw the same record compared to other types. In contrast, the duration time at 1st turn of S-type is longer, but 4th turn is shorter. Therefore, S-type requires faster speed than that of F-type at 4th turn. REFERENCES: Bartonietz K. (2000). A STUDY OF THE "IDEAL COACH" FOR THE ELITE LEVEL RUGBY FOOTBALL PLAYERS IN JAPAN

WASHIYA, K., OGAKI, R., KIUCHI, M., CHIBA, G., SHIMASAKI, T., IWAI, Y., HIGO, Y., KOYANAGI, R.

Chiba University of Commerce

Introduction Studies of the ideal coach have typically been asked to coaches what an ideal coach is (Yamamoto and Jogo, 2009). Therefore in previous researches, what players think about an ideal coach was not focused on. This study aims to examine what Japanese elite rugby football players think about an ideal coach. Methods Players from nine teams grouped into three different categories, are studied: high school teams, university teams, and company teams. All the teams studied, played in the semifinals of the national tournament in each category in 2011. A free answer method was adapted to correct the data. The data were classified by the KJ method, and analyzed by statistical methods using Fisher's exact test and Ryan's method. Results As a result, the four factors; 1) guiding skills, 2) coaching skills, 3) perceived knowledge of rugby, and 4) personality are found in all the team categories which define the recognition of an "ideal coach" for players. The factor "team management skills" is found for company team players only. While high school team players emphasize "guiding skills", university players also evaluate "coaching skills". Players in company teams regard "perceived knowledge of rugby" more than players from the other categories. Discussion Players in high school teams tend to demand guiding skills of coaches. That is resulted from that they are on the stages in which they build their identities (Takenouchi, et al., 2006). Players in university teams tend to demand coaching skills of coaches. That is resulted from that their identities are more stable than high school players and they have high motivation about improvement of their rugby football skills (Saijo, et al., 1993). Players in company teams tend to demand perceived knowledge of rugby football coaches. That is resulted from that they have already been matured as persons and as rugby football players. THE POST ACTIVATION POTENTIATION EFFECTS OF PLYOMETRIC EXERCISES ON JUMPER PERFORMANCE IN WELL TRAINED GYMNASTS

DALLAS, G., PARADISIS, G., PAPPAS, P., TSOLAKIS, C.

KAPODISTRIAN UNIVERSITY OF ATHENS

Introduction Plyometric training has been used as a warm-up method in order to improve subsequent power and strength especially in the sports of gymnastics. Drop jump (DJ) is a task that includes the so-called stretch-shortening cycle (SSC), where an eccentric contraction precedes a concentric contraction. The purpose of this study was to examine the acute post activation potentiation effects of different plyometric exercises on drop jump performance in well trained gymnasts. Methods Thirty-five male and female well trained gymnasts (age 20.37 ± 4.20 years, body mass 58.41 ± 10.14 Kg, height 1.66 ± 0.09 m) volunteered to participate in this study. The condition stimuli were two different plyometric exercises (Rondat & Tuck jumps) performed under two separate visits to assess drop jump performance. A Pre test performed before the start of the intervention program which consisted of 1 set of 10 Rondats and 2 set of 5 tuck jumps (TJ). A post test was performed immediately after and 3 mins (Post 3), 6 mins (Post 6) and 9 mins (Post 9) after the end of the intervention program. Results Significant DJ height main effects for time and gender were found indicating that men performed better than women and that DJ height was increased over time. Further, a time x gender DJ height main effect for time was found and the Post hoc analyses for DJ height comparing the baseline values showed large differences immediately after and after 6 and 9 min for males and immediately after, remaining unchanged thereafter for females respectively. Discussion Both plyometric exercises had a positive effect on drop jump performance (Hilfiker et al, 2007), throughout the rest interval range of 1-9 minutes in the male gymnasts, with no change in performance in the female gymnasts. Plyometric exercises were effective warm-up methods and produce PAP effect thus performance was improved. References Hilfiker, R, Hubner, K, Lorenz, T, Marti, B. (2007). THE ALTERNATION OF BRAIN ACTIVITY IN FRONTAL CORTEX WITH PROFICIENCY LEVELS IN TRAMPOLINE ATHLETES

YAMAZAKI, K.1, YAMAZAKI, H.2, ITOH, N.2

1) Toyo University, 2) Nippon Sports Science University

Introduction It is generally concerned to be difficult to discover the future skills development in beginner athletes, especially in the sports events that have a few athletes like the trampoline. Coaches have to predict, depending on their subjective evaluation, whether a beginner athlete will be a competent athlete having good potential and skills or not, in the athletes' early practical stage. If the coaches are able to know athletes' future skills in the early stage of the training process or athletes' skills development, it will provide them a lot more time to train athletes and improve their skills. In previous studies of motor learning which demonstrated the relationship between brain activity and motor learning, a brain activity will change according to process of motor learning. In this study, we hypothesized that there are some alternation of brain activities during the acquisition process of the trampoline jumping skills. To observe these alternations, we examined brain activities in frontal robe with motor imagery of trampoline jumping action. Methods 3 trampoline athletes were voluntarily recruited for this study. To observe spatio-temporal brain activity in frontal lobe, we used optical topography ETG-7100 (Hitachi medical, co. ltd., Japan). Optical probe (22ch) were put on the forehead, and subjects kept rest for few minutes before the measurement. The measurement protocol consisted by 15blocks. Each block includes 30seconds resting state period and 30seconds stimulation period. During stimulation period, subjects imaged the scene that the subjects are jumping. Jumping variation includes following 3 jumps: straight jump, double back and double twist. Each jump was included 5times in 15blocks sequence. Results and Discussion We analyzed the difference in brain activity according to subjects' completion of jumping skills. Brain activity in frontal cortex few changed in the jump variation which the subject has already completed. However, in the jump variation which the subject hasn't complete yet, the frontal cortex brain activity significantly changed in many measurement channels. In previous study, in the process of motor learning alter the brain activity especially in supplementary motor area. Once the person acquired the movement, the brain activity observed in motor area changes to supplementary motor area that controls the movement based on memories. Thought we didn't investigate about the brain activity by real body movement, we suggest that movement acquisition might change the brain activity. EFFECTIVENESS OF TACTICAL ACTIONS IN ELITE MEN'S ÉPÉE

IGLESIAS, X., TARRAGÓ, R.

INEFC-Barcelona, Universitat de Barcelona

Introduction Few scientific publications are devoted to the analysis of the temporal dynamics, technical and tactical determinants in fencing. To apply various actions (offensive, defensive and counter-offensive) successfully fencers should use preparatory actions. (Czajkowski, Z., 2009). The aim of this study is to analyse the different tactical actions and their impact on the score in elite men's épée. Methods This was done using an observational methodology based on an open and systematic process of non-participant observation with a nomothetic, punctual, multidimensional design (Anguera et al., 2011). 29 men's épée assaults were recorded in two World Championships (2013-14). The observation instrument used was an adaptation of the ESGRIMOBIS (Tarragó et al. 2015), and the LINCE v.1.1 (Gabin et al., 2012) software was the recording tool. Results A total of 1,466 phrases (379 different configurations) were recorded. 40% ended up in touch, with 17% in favour of the fencer who initiates the offensive action (fencer "A"), 15% opponent (fencer "B") and 8% touched twice. Only 2% of the phrases were performed by a single action between fencers, 72.4% in two actions and the remaining 15% appeared a third action; the remaining 11% is held by 4-9 exchanges of actions. Table 1 shows the distribution and effectiveness of the various tactical interactions in response to the pressure and prior preparation in relation to the fencer who initiates action (fencer "A"), and even a third level of interaction between rival ('A' vs. 'B'). Discussion As the main contribution of this study we emphasize that for the first time has been made a structuring of distribution and effectiveness of tactical actions in fencing. The offensive actions were the most commonly used (44.9%) followed by the defensive (33.0%) and counter-offensive (22.1%). The systematizing tactical actions performed proposes an excellent tool of tactical analysis in fencing, through which we can see how the effectiveness of the same phrase is different depending on the situation before -pressing and preparation- by two fencers. We emphasize that the counteroffensive actions are performed less but more effective for both fencers. References Anguera, M.T., Blanco-Villaseñor, A., Hernández-Mendo, A., & Losada, J.L. (2011). WORK TO REST RATIO IN FENCING: A ELITE MEN'S ÉPÉE STUDY

TARRAGO, R., IGLESIAS, X.

INEFC-BARCELONA (*Universitat de Barcelona*)

Introduction The first chronometric analyses published on fencing were made from the world championships épée 1981 (Lavoie et al., 1984). The measurement of work-to-rest ratios is important when investigating the physiological demands of intermittent sports such as fencing. The aim of this study is to determine the work-to-rest ratio in fencing competition and the temporal structure of the assaults in elite men's épée. **Methods** This was done using an observational methodology based on an open and systematic process. 29 men's épée assaults were recorded in two World Championships (2013 & 2014). The LINCE v.1.1 (Gabin et al., 2012) software was the recording tool. The Shapiro-Wilks test determined the non-normal distribution of temporal parameters. The differences between periods were analyzed through non-parametric Kruskal-Wallis test with pairwise comparison by Mann-Whitney. Results In the 29 assaults completed, all reached the 2nd period and of these, only five did not reach the 3rd period. The work time is 163,5 s (\pm 39,3) in the 1st period, 160,2 s (\pm 36,4) in the 2nd, and 118,8 s (\pm 59,7) in the 3rd period (3rd period $<$ 1st & 2nd; p <0.05). The rest time in the periods was 131,9 s (\pm 63,5), 146,1 s (\pm 81,7), and 169,1 s (\pm 121,5) respectively. The pause time between periods was, in the three periods of assault, 71,9 s (\pm 27,5), 80,2 s (\pm 23,8) and 29,6 s (\pm 8,8) (3rd period $<$ 1st & 2nd; p <0.001). The average "allez" time in each period was respectively 26,3 s (\pm 15,1), 21,5 s (\pm 10,3), and 16,4 s (\pm 11,6) (3rd period $<$ 1st & 2nd; p <0.001); and the average "halte" time was 16,7s (\pm 5,2), 18,0 s (\pm 7,2), and 19,3 s (\pm 8,1). The total assault time in direct elimination men's épée was 353,7 s (\pm 121,2), 367,6 s (\pm 114,7), and 281,1 s (\pm 177,9). **Discussion** The results of our study determine a work-to-rest ratio of 1:0.9 for men's épée assaults, similar to the 1:0.6 described by Lavoie et al. (1984) or the 1:1 cited by Roi & Bianchedi (2008). The ratio is similar to the women's foil (1:1.1) recently described by Wylde et al. (2013), and very different from the values observed in men's sabre assaults (1:6.5) and female (1:5.1). The work-to-rest ratio analysis data can help the coach identify specific physiological demands for each fencing modality: épée, foil and sabre. **References** Aquili, A. et al. (2013). KINEMATIC ANALYSIS OF JAVELIN THROWING IN JAPANESE ELITE THROWER.

KOYAMA, Y., NISHIMURA, T., MIYAUCHI, I.

Nihon University

Introduction The aim of this study was to investigate the kinematic factors of javelin throwing due to improvement of athletic performance in Japanese elite javelin thrower. **Methods** Subject of this study was Japanese male elite javelin thrower (Height: 186cm, Weight: 104kg, personal record: 85.96m (2013)) who participated in the 2008 and 2012 Olympic games. He performed Japanese 2nd ranking of 85.96m at the 47th Mikio Oda Memorial international amateur athletic game (Domestically competition) in 2013. Three dimensional analyses of javelin throwing were measured two competitions in Japan (91th Japan championship in athletics (2007) and 47th Mikio Oda Memorial international amateur athletic game (2013)). Throwing motion was recorded by two digital video cameras (120Hz) in each competitions. One of the video cameras was placed at the right side of the approach runway, the other one was placed behind the approach runway. Throwing motion was analyzed by using Frame-DIAS V for Windows application (DKH, Japan). In this study, horizontal velocity of wrist, elbow and shoulder in throwing arm were kinematic analyzed in each trials. And also, we calculated in joint angle of elbow in throwing arm and relative horizontal distance of grip position to shoulder joint during javelin throwing. **Results** In this study, subject was improved competition result from 2007 to 2013 season. He was competed in the two-time Olympic game and many of the world championship. And also, He had gold medal at the Asian games in 2011 (83.15m). In kinematic factors of javelin throwing in 2013 season, horizontal velocity of each joint was slightly increase after the left foot grounded compared to 2007 season. Elbow joint angle in 2007 season was more flexion from left foot grounded to release than the 2013 season. And also, relative horizontal distance of grip position to shoulder joint in 2013 season was located in backward from right foot to left foot grounded compare to the 2007 season. **Discussion** In generally, if flexed elbow from right foot to left foot grounded during javelin throwing, it is not possible to increase the javelin acceleration distance. In 2013 season, elbow joint angle was extended and increased javelin acceleration distance as compared to the 2007 season. From these result, it was considered that javelin throwing performance may affect by movement of the body including elbow joint angle in elite thrower. **References** R.J. Best, R.M. Bartlett C.J. Morriss. J Sports Sci. 11(4):315-328. 1993. Liu, H., Leigh, S., Yu, B. J Sports Sci. 28(13):1459-1467, 2010

OPTIMAL TRAINING LOAD FOR DEVELOPING MUSCULAR POWER

LYONS, M., KENNY, I., GRIFFIN, A., MAHON, S., LYNCH, G., WITHEROW, P., CARTY, P.

University of Limerick

Training with a load that optimises the development of muscular power is fundamental in field-based athletes. Previous research however, exploring optimal load in field-based sports is conflicting. The purpose of this study was to identify the optimal training load for development of muscular power in the back squat (BS) and bench press (BP) exercises and to determine if baseline strength levels affect optimal load. 50 field-based athletes (mean (\pm SD) age 21.6 \pm 3.22yrs; body mass 82.39 \pm 8.09kg; height 1.81 \pm 0.572m) volunteered to participate in this investigation. Each participant's 1 repetition maximum (1RM) for the BS and BP was initially determined using standardised procedures. Participants subsequently performed the BS and BP exercises at loads of 20-90% of their predetermined 1RM in a randomised order. Repeated measures ANOVA revealed that the optimal load for development of muscular power in the BP exercise was 50% and 60% of 1RM. Mean and peak power output, determined using a Fitrodyne, was significantly higher at 50% and 60% of 1RM compared to all other loads. The optimal load for development of muscular power in the BS was 70% and 90% of 1RM. The results of this study suggest show that relative load has a significant effect on average and peak power output in both the BS and BP exercises. Considerable inter-individual differences were also found in this study indicating that the load that maximises power output varies across individual athletes. Furthermore, stronger athletes generate optimal power outputs at a lower relative load compared to weaker athletes. The nature of the exercise as well as baseline strength levels need careful consideration when prescribing training load for the development of muscular power in field-based athletes.

EFFECTS OF ALTITUDE CONCURRENT STRENGTH AND ENDURANCE TRAINING ON NEUROMUSCULAR FUNCTION

STROJNIK, V.1, TOMAŽIN, K.1, ŠTIRN, I.1, ŠTRUMBELJ, B.1, GARCÍA-RAMOS, A.2, PADIAL, P.3, ARGÜELLES-CIENFUEGOS, J.3, DE LA FUENTE, B.3, FERICHE, B.2

University of Ljubljana

Introduction Most elite sportsmen, especially from endurance disciplines, use altitude training. At the normal altitudes, the concurrent strength and endurance training compromises the development of muscle mass, strength, and power compared with undertaking resistance exercise alone (Fyfe et al., 2014). No study has examined what happened with neuromuscular function after the concurrent training at high altitude. Therefore, the aim of this study was to analyze effects of altitude concurrent strength and endurance training on neuromuscular function. **Methods** Sixteen swimmers belonging to the National Slovenian swimming team (age = 33.5 ± 6.7 years, height = 173 ± 9 cm, mass = 73.5 ± 13.9 kg) volunteered in the study. They performed three weeks of concurrent strength and endurance training at normal (295 m asl) and increased altitude (2320 m asl). The training content was in both cases kept similar as much as possible. Both training periods were performed at the same calendar time, but with a year difference. Before and after each training period the subjects performed isometric steady and explosive knee extension. Additionally, femoral nerve was stimulated to obtain maximal twitch of the knee extensors. **Results** After the increased altitude training MVC knee torque significantly increased ($P < 0.05$) but not after the normal altitude training, however, the differences in training effect were not different. Rate of torque development was not significantly changed after any of training regimes as well as twitch peak torque. **Discussion** After the altitude training MVC knee torque increased but not after the sea level training. Since the differences between training effects were not significantly different, this cannot be considered as a strong evidence that altitude training attenuate muscle strength. Furthermore, the increased maximal knee torque may be related to acute improvement in strength due to increased altitude (Feriche et al., 2014). As there were no significant changes in twitch parameters, it can be expected that increased MVC resulted from improved muscle activation. It was concluded that concurrent training at increased altitude was not more effective in changing neuromuscular function than training at normal altitude. **References** Feriche B, García-Ramos A, Calderón-Soto C, Drobnič F, Bonitch-Góngora JG, Galilea PA, Riera J, Padial P. QUANTITATIVELY MEASURED VARIATION OF PLAY BY SUBSTITUTED TEAM MEMBERS IN BALL GAMES

TAZUKE, S.1, AIHARA, S.2, TANAKA, T.2, BAN, H.2, GOUDA, N.3

Doshisha University*, *²3Hitachi,Ltd*,

Introduction Substitution of a player is a tactics in the ball game. Yet no quantitatively study on play effected by substituted team members exists. The purpose of this study is to achieve the quantitative variation of the play caused by substituted players. **Methods** Samples were 24 students (17 men and 7 women, aged 21.79 ± 0.83 years/ Faculty of Health & Sports Science). The experiment was conducted based on the rules of "Anbielen & Orientieren Test Heidelberg Ballschule". That is, a ball game conducted by 2 teams of 3 players each on 9 meters square court. Players can neither walk nor run in possession of a ball. Total of successful pass of the ball was competed in the game. All subjects played 24 games in total with different teams. The game was a set of 2 minutes play 2 minutes break. 4 factors (running frequency, average running time, average exercise intensity METs and running rate) were calculated with the measured data by Three-Axis Acceleration Bracelet. The variation of the play caused by substituted players was evaluated by the standard deviate (SD) of the 4 factors. **Results** The running frequency were 7.38 ± 0.83 times, the average running time were 22.99 ± 13.54 sec., METs were 6.88 ± 0.73 METs and the running rate were 90.0 ± 4 %. The SD of the running frequency of 1 subject was more than double SD, the SD of the average running times of 4 subjects were more than double SD, the SD of the running rate of 4 subjects were more than double SD. There is no subject who had 2 or more factors more than double SD. **Discussion** It was suggested as follows. There are players who change their play adjusted to other players. 3 factors: average running time, running frequency and running rate in a game are the characteristic of the players. **Conclusion** This study is the first quantitative study investigated the variation of plays of player in the ball games. It shows that there are players who changes and adjusts their play by other team players. **Acknowledgement** This research is partially supported by the Center of Innovation Program from Japan Science and Technology Agency, JST. SKILL TESTS FOCUSING ON BALL MANIPULATION AND AGILITY IN BASKETBALL CLASSES FOR PHYSICAL EDUCATION MAJORS

KAWAZURA, T., YAITA, A., AOYAGI, O.

1) KYUSYUKYORITSU UNIV, 2) FUKUOKA UNIV

Introduction Evaluations using skill tests are effective in university basketball classes. However, in faculties related to physical education, many students regularly practice ball sports other than basketball. For such players, the results of basketball skill tests do not always depend on the effect of basketball classes, but rather on the training effects of the student's sport of choice. Thus, this study aimed to investigate which skill tests can discriminate between students who regularly play basketball and those who do not, which is useful when grading students in basketball classes at sport-related universities or faculties. **Methods** Subjects were 144 physical education majors enrolled in a basketball class at a sport-related university (31 basketball players and 113 novices who did not play basketball regularly). Fifteen skill tests were originally developed by the authors based on the fundamental skill tests recommended by JBA (2002). The Student's t-test was applied to test the differences in skill test results between basketball players and novices. **Results** The t-test showed significant differences between the two groups in the following seven tests: 1) Kick (basketball players' mean [BP's] = 4.736 sec [standard deviation (SD)=0.807 sec], novices' mean [N's] = 4.424 sec [SD=0.777 sec], $t_0=1.95$, $df=142$, $p<0.05$); 2) Front turn (BP's = 6.255 sec [0.569], N's = 6.597 sec [0.510], $t_0=2.88$, $df=142$, $p<0.01$); 3) Back turn (BP's = 6.973 sec [0.533], N's = 7.214 sec [0.535], $t_0=2.20$, $df=142$, $p<0.05$); 4) Figure eight (BP's = 16.532 times [4.682], N's = 14.819 times [3.072], $t_0=1.89$, $df=37$, $p<0.05$); 5) Body circle (BP's = 17.677 times [9.748], N's = 11.677 times [2.622], $t_0=3.34$, $df=31$, $p<0.01$); 6) Body circle B (BP's = 12.952 times [3.666], N's = 12.952 times [2.929], $t_0=3.63$, $df=142$, $p<0.01$); and 7) Catching the ball at the back and front of the body while throwing it between legs (BP's = 15.968 [6.222], N's = 13.885 times [3.855], $t_0=1.75$, $df=36$, $p<0.05$). Since significant differences between basketball players and novices were detected in Front turn, Back turn and Kick, which are tests related to footwork, it can be assumed that the footwork and turns specific to basketball differ from those of baseball and volleyball. Significant differences were also detected in the ball manipulation tests Figure eight, Body circle, Body circle B and Catching the ball at the back and front of the body while throwing it between legs. One possible explanation is that volleyball or

rugby players who do not play basketball do not frequently roll the ball and are not familiar with maneuvering with a large ball like a basketball.

SELECTION OF THE OLDEST: RELATIVE AGE EFFECTS IN THE UEFA YOUTH LEAGUE

ROMANN, M., JAVET, M., TAKACS, S.

Swiss Federal Institute of Sport Magglingen

Introduction Differences in age within annual cohorts (relative age) result in performance discrepancies between children and youth which are referred to as relative age effects (RAEs) (Cobley, Baker, Wattie, & McKenna, 2009). Being relatively older compared to being relatively younger, is predictive of better physical capacities such as aerobic power, muscular strength, endurance and speed. This generates consistent participation inequalities, selection biases and may lead to a drop out of potential talents. Methods In this study, 1208 male youth soccer players (age: 16.9 ± 0.9) who participated in the new UEFA Youth League, which has the aim to promote talent for elite soccer, were evaluated. The prevalence of RAEs according to playing positions and countries was analysed. All data were obtained from the FIFA website. The year was divided into four quarters (Q1: Jan. to Mar.; Q2: Apr. to Jun.; Q3: Jul. to Sept.; Q4: Oct. to Dec.). From the original data, chi-square tests, effect sizes and odds ratios (ORs) were calculated. Results Our comparisons showed significant RAEs with medium effects. Youth players born in Q1 were 3.35 times more likely to be selected than players born in Q4. Significant RAEs were found for every age group (1996, 1997, 1998 and 1999). The effect size in the different age groups varied between medium (1996 and 1997) and large (1998 and 1999). The younger age groups showed significantly higher RAEs than the older age groups. The analysis did not reveal any influence of playing position on the size of the RAEs. However, the results showed significant differences in relation to country, as well as the absence of RAEs in teams from Belgium, Bulgaria, Cyprus and Slovenia. Discussion Overall, the UEFA Youth League is highly biased by RAEs. Thus, it seems RAEs reflect a type of developmental barrier that may be preventable by implementing appropriate solutions in the future (Cobley, et al., 2009; Romann & Cobley, 2015). Therefore, international and national federations should adopt detailed regulations that force clubs to improve their talent identification processes. Especially for a small country like Switzerland, which has a rather small talent pool, any future reduction of RAEs may provide a substantial performance enhancement at elite senior level. EFFECTS OF THE LONG TIME CYCLING ON THE OUTPUT OF THE LOWER EXTREMITY MUSCLES IN THE BIKE COMPETITION

TAGO, T., KANEKO, K., TSUCHIOKA, D., ISHII, N., WADA, T.

Tokushima Bunri University

Introduction In long-distance bicycle racing, cyclists must maintain or increase their speed depending on the circumstances. This requires both improving the endurance of the circulatory organs and efficient muscle output. Although cycling movements have been well studied, few previous investigations have investigated the output of the leg muscles from the association between actual cycling for long periods and the simulators frequently used in training. In this study, we compared muscle output during actual cycling and simulated cycling, with the aim of obtaining basic knowledge useful for providing guidance on cycling movements over long periods. Methods The subjects were a total of six of the male college student three skilled persons, and three unskilled persons belonging to the cycling team of the University. In actual cycling, the subjects cycled along an undulating route often used in training by competitive cyclists, while in simulated cycling they used a simulator. Both sessions 60 minutes for trial time. In both sessions the subjects adopted the posture they normally used when cycling, and pedaled at whatever rate they chose. As they cycled, they used a heart rate monitor to maintain their heart rate at 75%-80% of their previously measured maximum heart rate. Tibialis anterior muscle, gastrocnemius, vastus medialis, vastus lateralis, rectus femoris, biceps femoris, gluteus maximus, gluteus medius muscle was measured during cycling. Results Skilled person from the second half of the trial had increased activity of hip extension muscles, such as gluteus medius and gluteus maximus muscles, On the other hand, Unskilled person had increased the activity of the knee joint extension muscle group, such as vastus medialis and vastus lateralis muscle. In addition, in the simulation trial, activity time of lower limb muscles was decreased. Discussion We found that compared with inexperienced cyclists, experienced cyclists did not increase muscle activity during the first half of the session, while during the second half they increased the activity of the gluteus medius, gluteus maximus, and other hip extensor muscles. THE ANALYSIS OF TACTICAL SKILLS IN BALL GAMES IN LOWER GRADE ELEMENTARY SCHOOL CHILDREN

OKUDA, T.I, MORITA, N.I, AMBE, H.I, NAKASE, Y.2, BONO, S.3, SHIDE, N.I, SATO, T.1

1.Hokkaido Univ. Education Iwamizawa; 2.Tokyo Seitoku Univ. ; 3.Hiroshima Bunka Gakuen Univ.

Introduction In the ball game, it is important to win that players improve physical fitness as well as tactical skills. Previous studies investigated effects of cognitive training on tactical skills for ball games and/or game performance (e.g., game performance assessment instruments) in laboratory or field settings (Griffin, 1999). Participants in these studies were higher grade elementary school children, but not lower grade elementary school children. It is important to understand that how children acquire naturally tactical skills for ball games. The purpose of this study was to investigate the tactical skills for ball games in lower grade elementary school children. Methods First, 2nd and 5th grade elementary school children participated (1st graders, 6-7 years, n = 57; 2nd graders, 7-8 years, n = 54; 5th graders, 10-11 years, n = 54). The children played a 5-min 7-versus-7 generic ball game with 2 goals at each end. In the ball game, children pass a ball to playmate to goal, but are not able to dribble a ball. A digital video camera was placed to record positional information of students and a ball during games. Positional data of a ball and children were calculated by the direct linear transformation method. Tactical skills of "off the ball movement" were assessed by the 3 categories for decision-making of the play by Stiehler et al. (1988). Three categories were Level 1, "children moved to appropriate position", Level 2, "children moved to inappropriate position", and Level 3, "children just watched, and did not move". Data of lower graders were compared with those of 5th graders. X² test was used for comparison. Statistical significance was set at 5%. Results First graders showed 3.84 ± 3.27 sec of ball possession from catching a ball to passing the ball to a playmate, 3.45 ± 2.28 m of passing distance, and 3.38 ± 1.83 m/sec of passing ball velocity. Second graders showed shorter duration of ball possession (3.00 ± 2.42 sec), longer passing distance (5.70 ± 4.46 m), and higher passing ball velocity (5.14 ± 8.18 m/sec), compared to 1st

graders. In off the ball movement of 1st graders, 39.2% of behaviors were categorized into Level 1 in a 5-min goal game. Second graders showed 48.1% of Level 1 behaviors in a game. X² test for off the ball movement between 1st and 5th graders demonstrated significant difference ($\chi^2 = 7.61$, df=2, p=0.011). Difference between 1st and 2nd graders by X² test was significant ($\chi^2 = 5.67$, df=2, p=0.029). Discussion Our results from the present study suggested that compared to 1st graders, 2nd graders improved ball game performances and decision-making ability in off the ball movement. RELATIONSHIP BETWEEN SPRINTING ABILITY WITH CHANGE OF DIRECTION IN THE REACTIVE CONDITION AND REACTION TIME IN FEMALE SOCCER PLAYERS

IGUCHI, Y., ISHIHARA, Y., YAMANAKA, K., MAEHANA, H., YOSHIMURA, M.

Juntendo University

Background: Soccer players are required to accelerate, decelerate, and change directions throughout the game. These movements are often in response to game cues, such as the movements of the ball and actions of other players (Bangsbo, 2015). The purpose of this study was to investigate the relationship between sprinting ability with change of direction (COD) in the reactive condition and reaction time (RT). Methods: Seventeen female university soccer players participated in this study. From a 20-meter (m) sprint test, we measured the sprint time for COD in the reactive and planned conditions. For COD in the reactive condition, the subjects had to make a 90-degree cutting movement at the 10 m point, where they had to decide whether to turn right or left according to a light stimulant at 7.5 m from infrared Smartspeed timing gates. Similarly, for COD in the planned condition, the subjects made a 90-degree cutting movement at the 10 m point. The time to perform each test was registered, and the difference between the two conditions was calculated to determine the reactive time. We also measured the RT using a visual stimulus system. Results: The mean values and standard deviations from the 20 m sprint test were 3.641 ± 0.113 seconds (sec) : the sprint time for COD in the planned condition was 4.466 ± 0.139 sec, and for COD in the reactive condition, 4.769 ± 0.182 sec ; the reactive time was 0.303 ± 0.179 sec ; and the RT was 0.348 ± 0.030 sec. The sprint time for COD was longer in the reactive than the planned condition. Furthermore, the sprint time for COD in the reactive condition was associated with the reactive time, but not with RT. Conclusion: This study suggested that the sprint time for COD in the reactive condition was not correlated to the RT.

Health and Fitness

COMPARISON OF UPPER BODY STRENGTH GAINS BETWEEN MEN AND WOMEN AFTER 10 WEEKS OF RESISTANCE TRAINING

GENTIL, P.1, PEREIRA, M.C.2, CASTANHEIRA, R.P.M.2, STEELE, J.3, PAOLI, A.4, BOTTARO, M.2

1 University of Goias, Brazil; 2 University of Brasilia, Brazil; 3 Southampton Solent University, United Kingdom; 4 University of Padova, Italy

Introduction Resistance training (RT) offers benefits to both men and women. However, the studies about sex's difference in response to a RT program are not conclusive and few data are available about upper body strength response. The aim of this study was to compare elbow flexor strength gains in men and women after 10 weeks of RT. Methods Forty four college-aged men (22.63 ± 2.34 years) and forty seven college-aged women (21.62 ± 2.96 years) participated in the study. RT was performed two days a week for 10 weeks. Peak torque (PT) of the elbow flexors was measured with an isokinetic dynamometer before and after the training period. Results PT was greater in men than women pre- (49.35 ± 10.18 vs. 25.09 ± 4.89) and post-training (55.08 ± 9.95 vs. 28.04 ± 5.52). Both males and females significantly increased elbow flexor strength ($p < 0.05$), however, strength changes did not differ between sexes (11.61 and 11.76% for men and women, respectively). Effect sizes were 0.57 and 0.56 for men and women respectively. Discussion Previous studies showed that female's strength, when normalized to muscle mass, is comparable to male's values (Hannah et al., 2012) and that the higher male absolute strength is mainly due to higher muscle mass (Ivey et al., 2000). Therefore, one can suggest that the relatively short period of training of the present study could be insufficient to produce a significant muscle growth, which resulted in similar strength increases between sexes. However, this does not seem to be the case as Abe et al. (2000) also reported similar degrees of hypertrophy for males and females after ~6 weeks into an RT intervention with a similar time course of changes for both strength and hypertrophy between sexes. Although the anabolic and ergogenic effects of testosterone are well known, evidence suggests that progesterone may also have an important anabolic effect (Sakamaki et al., 2012; Smith et al., 2014), which could explain the similar adaptations between sexes. In summary, there seems to be no limitations in upper body strength development in women. References Abe T, DeHoyos DV, Pollock ML & Garzarella L. (2000). Eur J Appl Physiol 81, 174-180. THE ASSOCIATION OF PHYSICAL ACTIVITY WITH BODY COMPOSITION AND GLYCEMIC MARKERS IN MIDDLE-AGED AND OLDER JAPANESE

TABATA, S., SERA, Y., AZUMA, K., NAGANO, M., TAKAYAMA, M., SHIOMI, E., SUGINO, Y., IWAO, Y., ISHIDA, H., MATSUMOTO, H.

Keio university hospital

Introduction: Sedentary behavior and reduced physical activity are associated with not only increased body fat but also loss of muscle mass and strength (sarcopenia) especially in elderly individuals. In recent years, it has been revealed that muscle fatty infiltration as well as visceral fat accumulation and sarcopenia, due to physical inactivity contributes to decreased insulin sensitivity and abnormal glucose tolerance. Therefore, it is necessary to evaluate the association of physical activity with body fat, muscle, and glycemic markers to prevent metabolic syndrome and type 2 diabetes. Methods: Subjects were 79 males (age; 64.1 ± 12.5 , BMI; 24.0 ± 3.2) and 90 females (age; 65.4 ± 10.5 , BMI; 22.2 ± 4.3) participated in the medical checkup in Keio University Hospital (Tokyo, Japan). In addition to exercise habit and subjective walking speed (slow, normal or fast) by the questionnaire used in specific medical examination, sedentary time (ST) was evalu-

ated using an original questionnaire. The subjects were divided to active group ($ST \geq$ median values) and sedentary group ($ST <$ median values). Visceral fat area (VFA) and cross-sectional areas (CSA) of anterior abdominal walls (AAW), psoas major muscles (PM), and erector spinal muscles (ES) were measured by CT images at the umbilical level. CT values of them were also measured as the index of intramuscular fat. Unpaired T test and one-way analysis of variance (ANOVA) were used to assess the association of physical activity with VFA, CSA and CT value of AAW, PM, and ES, and glycemic markers (fasting plasma glucose, HbA1c, and HOMA-R) in each sex. Multivariate logistic regression analysis was used to adjust for age and BMI. Results: 63.3% of males and 52.2% of females had exercise habit. The percentage of slow, normal, and fast subjective walking speed were 24.1, 45.6, and 30.4% in males, 20.0, 53.3, and 26.7% in females. The median values of ST were 6.0 and 5.6 h/day in males and females. After adjustment for age and BMI, exercise habit was positively associated with CSA of AAW and ES ($p=0.004$ and 0.021) in male, CSA of AAW, PM, and ES ($p=0.026$, 0.028 , and 0.037) in females. Slow walking speed was negatively associated with CSA of AAW and ES in males ($p=0.006$ and 0.003). In active group, CSA of PM was significantly higher than sedentary group ($p=0.009$) in males. Physical activity was not associated with VFA, CT values, and glycemic markers in both males and females. Conclusion: Physical activity was associated with CSA of abdominal muscles. Different associations of walking speed and sedentary behavior with body composition by sex were also implied. This study also suggested the possibility that exercise and sedentary behavior have influence on the different muscles in males.

RE-VERIFICATION WITH REGARD TO SCAMMON'S GROWTH CURVE —ANALYSIS BASED ON WAVELET INTERPOLATION MODEL AND CROSS CORRELATION FUNCTION—

FUJII, K.

Aichi Institute of Technology

Introduction The Scammon's growth curve, even during the 80 years since, has been applied to a number of fields. However, one has to wonder if all human characteristics are included in this 4 pattern growth curve classification. Till now, the Scammon's growth curve has yet to be subjected to scientific verification. In this study, this assessment was verified by applying a cross-correlation function in analyzing changes from collapsing one of the curves to examine their similarity. Because of that, cross correlation function can then be applied to the quantified curve by Wavelet Interpolation Method. Methods : The data utilized for analysis, cross-sectional growth data from age one to 20 was used for the four attributes classified by the Scammon growth curve. This data was comprised of brain weight (neural type), thymus (lymphoid type), testicle (genital type), and liver (general type). A cross correlation function is used to show the similarity between two waveforms, and the cross correlation function may be evaluated by convolving one function. In this study, a cross correlation function was assumed from the velocity curve values found from differentiation using the WIM for Scammon's growth types. < Analytical procedure>: WIM (Wavelet Interpolation Method) was applied to longitudinal growth data consisting of attributes and organs. A cross correlation function was applied to the measured developmental indicators found by WIM and the velocity curve values. Results Visual assessment of the behavior of the velocity curves suggests similarity with the four patterns proposed by Scammon. Thus the dissimilarity between the growth curves was first examined by applying a cross correlation function. Dissimilarity between the four physical attributes was derived by cross correlation function with the supposition that the dissimilarity might vary between each of the patterns. $R = 0.75$ between brain weight (neural type) and thymus (lymphoid type), with an inverse correlation between brain weight and testicle (reproductive type) of $r = -0.45$. There was also an inverse correlation between brain weight and liver (general type) with $r = -0.63$. High correlation was indicated between thymus and testicle ($r = -0.7$), thymus and liver ($r = -0.8$), and testes and liver ($r = 0.9$). Discussion There are unanticipated possibilities of similarity between brain weight and thymus, and testicle and liver. What can be newly proposed, therefore, is that growth curve types can be classified as neural, lymphoid, and general body types, with the genital type included in the general body type. The genital type, visceral type, and morphological type are included within the general body type. References Fujii K, and Matsuura Y. (1999) Analysis of the growth velocity curve for height by the Wavelet Interpolation Method in children classified by maturity rate. Am J Hum Biol, 11, 13-30. Contact : fujii@aitech.ac.jp

SECULAR TRENDS IN PHYSICAL GROWTH INDICATORS IN INFANTS AND YOUNG CHILDREN

SAITO, N., FUJII, K., KASUYA, K., KANI, Y.

Aichi Institute of Technology

Introduction There have been no analyses in Japan that used mathematical functions to investigate changes over time in physical growth records of infants and young children. In this study, we investigated secular changes in growth velocity in the physical growth of infants and young children using the wavelet interpolation method, and examined the composition of secular changes in physical growth indicators. Methods The subject data were physical growth survey records for young boys and girls published by the Ministry of Health, Labor and Welfare in 1960 and 2000. The physical growth items used in the study were height, weight, chest circumference, and head circumference. The wavelet interpolation method was applied to these items for the period from age 0 to 6 years, and the derived growth distance curves and growth velocity curves were analyzed. Results It was shown that the values at birth were higher in 1960 than in 2000 for both boys and girls, but that after 6 months of age the values for 2000 exceeded those for 1960. From the largest peak velocity (LPV) soon after birth, obtained from the analysis of the growth velocity curve, there were no findings that showed clear secular changes in either boys or girls. However, a clear increasing trend was seen in the LPV for all items in both boys and girls in 2000, compared with 1960. The age at first local peak velocity (LPV) remained unchanged in boys compared with the past, but in girls slightly earlier trends were seen in all items. Discussion Thus, in the secular changes in the composition of physical growth indicators in infants and young children, it was found that in 2000 children were slightly smaller at birth, but then matured quickly, and grew larger compared with children in 1960. CHANGES OF BODY WEIGHT AND SELF-IMAGE IN STUDENTS IN SCHOOL FULL-TIME

BRITO, L.M.S., PEIXOTO, M.B., LEITE, N., CAT, M.L.N., BOGUSZEWSKI, M.C.S.

Federal University of Parana and CAPES

Introduction The increase in overweight rate among adolescents has been of concern today. In addition to being overweight are associated with many diseases in adulthood and also the social pressure of an ideal body and may cause great anxiety. Therefore important to evaluate the image that adolescents enrolled in schools Full time has on your body weight and check how much this is true. Methods Observational, cross-sectional, conducted in three schools full-time. The questionnaire Youth Risk Behavior Surveillance (YRBS) was ap-

plied followed by collection of anthropometric data (weight and height) and calculated BMI z score by Anthro plus the World Health Organization(WHO) program, obtained the same day the questionnaires. Results 270 adolescents were evaluated and 150 girls with an average age boys 12.67+ 1.05 and 12.68 + 1.15. 184 (68.14%) individuals self-reported being with adequate weight and 86 (31.85%) reported being with the weight higher than expected. When compared with the results obtained through the BMI z score 60 (22.44%) were overweight and the other weighing adequate or below normal for age and height ($p = 0.20$, $x^2 = 1.13$). And, for sex, 99 girls (66%) reported being of normal weight and 51 (34%) above the weight. The calculus BMI showed 117 girls (78%) were evaluated eutrophic and 33 (22%) with excess weight ($p = 0.34$, $x^2 = 0.87$). In boys, 85 (70.83%) reported being with adequate weight and 35 (29.16%) overweight. The BMI calculation showed 93 (77.5%) children with normal BMI and 27 (22.5%) overweight ($p = 0.76$, $x^2 = 0.09$). Discussion The body appearance has received great emphasis and value in today's society. The search for a body image often idealized by the media, social groups and the adolescents own sometimes triggers behaviors that can compromise the healthy. The results of this study show that adolescents do not have a distorted image of their body weight when we analyze the differences between proportions. Girls tend to be more dissatisfied with their body image compared to boys. Conclusion Students Full-Time seem to have satisfactory image and true body weight.

ONE-YEAR CHANGES IN ACTIVE TRAVEL TO SCHOOL AND PHYSICAL ACTIVITY IN CHINESE CHILDREN

WONG, S.1, HUANG, W.2, HE, G.1

1The Chinese University of Hong Kong; 2Hong Kong Baptist University

Introduction Cross-sectional studies have shown a positive association between active travel to school and overall physical activity (PA) in school-aged children. However, the longitudinal relationship between active travel to school and PA is far from clear. This study aimed to investigate the association between a change in travel mode to school and one-year changes in PA among children in Hong Kong. Methods Data from 677 children aged 7–10 years (56% boys) who participated in the Understanding Children's Activity and Nutrition (UCAN) study were analyzed. During the 2010/11 and 2011/12 school years, the children wore an accelerometer for a week and their parents completed a questionnaire about the children's modes of travel to school and non-school destinations. Associations between a change in the mode of travel to school and changes in moderate-to-vigorous PA (MVPA) on weekdays and over a week were determined using linear mixed models, adjusting for age, sex, child's body weight status, parental educational attainment, baseline values, and frequency of walking to non-school destinations. Results Compared to children who consistently used passive travel modes, a change from passive to active travel to school was positively associated with changes in the percentage of time spent in MVPA ($b = 1.32$, 95% CI = 0.63, 2.02) and MVPA min/day ($b = 10.97$, 95% CI = 5.26, 16.68) on weekdays. Similar results were found for weekly MVPA. Discussion Age-related decline in MVPA was obvious in all of the children except those who changed from a passive to an active mode of travel to school. Compared to consistent passive commuting, a change from a passive to an active mode of travel to school was positively associated with changes in MVPA. The findings suggest that promoting active travel to school may be helpful in combating age-related decline in PA for some children. Maintaining active travel to school may not on its own be sufficient to hinder the decreasing trend in MVPA with age. Contact hsswong@cuhk.edu.hk

WHOLE BODY VIBRATION TRAINING AS A PREVENTIVE WORKPLACE-BASED SPORTS ACTIVITY: A RCT

KAEDING, T.S.1,2, BIENECK, M.2, KÜCK, M.2, STEIN, L.2

1: Carl von Ossietzky University of Oldenburg, 2: Hannover Medical School (MHH)

Introduction The workplace is a suitable place for the introduction of health-orientated physical activity interventions and physical activity in workplace health promotion can improve physical capacity (Shephard, 1996). Whole body vibration training (WBVT) is considered to be an effective and well-suited preventive intervention for unfit people (Marin & Rhea, 2010a; Marin & Rhea 2010b). The goal of this study was to determine whether WBVT can improve basic physical abilities. Additionally, the study addresses its safety, suitability and the compliance with it. Methods 119 subjects (78% female, mean age 41.6 ± 9.8 yrs, mean BMI 25.4 ± 4.1 kg/m 2) were randomly allocated to an intervention group (INT, n=60) and a control group (CON, n=59). The INT participated in an unsupervised WBVT 2.5 times per week for 6 months with a progressive increase of intensity. At the beginning and after the intervention period, data were collected using jumping mechanography, progressive isoinertial lifting evaluation and a static posturography. Results There were no significant differences between the groups regarding mean change from baseline in maximum power (INT: 0.02 ± 0.17 kW, CON: -0.03 ± 0.19 kW, $p=0.41$), maximum velocity (INT: 0.01 ± 0.07 m/s, CON: 0.01 ± 0.09 m/s, $p=0.53$) or any other outcome parameter. However, we found a trend ($p=0.062$) regarding a positive effect of the intervention on the maximum jumping height in the exercise group. Whereas it improved in the exercise group (BT 0.3 ± 0.1 m, AT 0.4 ± 0.1 m), it was unchanged in the control group (BT 0.3 ± 0.1 m, AT 0.3 ± 0.1 m). The overall attendance rate was 71.6% and no unwanted side effects were detected. Conclusion The intervention showed no significant effects on the measured parameters of physical capability in the study population. However, we found a trend regarding a positive effect on the muscular capacity of the lower extremities in terms of the maximum jumping height. The lack of effectiveness of WBVT might be due to suboptimal individually configured training parameters (Cochrane, 2011). The compliance with the unsupervised WBVT was good, and we showed that this intervention is safe and feasible as workplace health promotion within the study population. Certainly, WBVT appears to be ineffective as a stand-alone intervention for primary prevention. The optimal training parameters for the use of it as a preventive workplace-based intervention should be studied further. References Shephard RJ. STRENGTH TRAINING USAGE WITH SKOLIOSIS OF S II DEGREE IN VIEW OF BODY DEFECTS FOR GIRLS 17-19 YEARS OLD

SHKLYARENKO, A., KOVALENKO, T., BUSHTETS, L.

Kuban State University branch in /Slavyansk-on-Kuba, Russia/; Volgograd State University / Volgograd, Russia/

Introduction When scoliosis due to anatomical changes to chest and the gibbus formation observed on girls 17-19 years old cosmetic side analysis of the disease are deeper [2]. The relevance of the present study caused to necessity to study the effectiveness strength training usage over the cosmetic correction of body deformities on girls 17-19 years old who have scoliosis I-II degree. Methods For cosmetic defects of the body attributed: the asymmetry of shoulder blades and waist triangles, the deviation of body from longitudinal axis. Data

which are presented from work obtained in the survey basis of 86 girls of 17-19 years old with scoliosis I-II degree, diagnosed by radiograph. Results Independent of strain localization in 87% of the surveyed girls with I scoliosis degree recorded an asymmetry blades and waist triangles and the deviation of body from longitudinal axis. In general, the scoliosis of I degree, regardless of age, location, and shape deformation, cosmetic changes of the body are small and are not subject to a visual self-esteem. When II degree scoliosis severity of symptoms was associated with visual abnormalities in body structure. In 46% of surveyed women occurred horizontal asymmetry of the breasts. In general, in II degree scoliosis cosmetic value of 17-19 years old girls was exacerbated by structural changes in the body shape that is not amenable to self-correction. For training major muscle groups, taking into account the structural changes in the body shape in girls with I-II degree scoliosis was used fitness equipment of various modifications. The basis of the designed strength training is a cyclic repetition weight training, selected in accordance with a particular scheme and carried out in a consistent manner simulators change. Received data give reason to believe that in the course of regular use of weight training in the gym, girls are significantly increases the efficiency of motor stereotypes built on muscular effort and volitional factors. Discussion Considering cosmetic body defects - scoliosis can be attributed to the conditions that lead to the exit of the patient beyond the standard framework of existence, the usual for most healthy people. Experimentally proved that the leading role of force exposure as a correction actions, leveling body cosmetic defects and ensure the stability of the spine, especially in females. HYPERGLYCEMIA IS REDUCED AT POSTPRANDIAL MOMENTS OF 24 HOURS AFTER LOW INTENSITY RESISTANCE EXERCISE IN WOMEN WITH TYPE 2 DIABETES.

ANDRADE, K.T.P.1, CRUZ, L.C.2, TEIXEIRA-ARAÚJO, A.A.2, SANTOS, B.M.R.2, ROCHA, T.C.O.G.2, SILVA, M.A.F.2, CARVALHO, F.O.2, MOREIRA, S.R.2

1. Pernambuco University (UPE) 2. Federal University of Vale do São Francisco (UNIVASF)

Introduction Type 2 diabetes (T2DM) is characterized by postprandial hyperglycemia, which is a major predictor of chronic vascular complications and aerobic exercise has been suggested in reducing the hyperglycemic state (Manders et al., 2010). However, few evidence of resistance exercise (RE) has been demonstrated by comparing the effect of different intensities in the postprandial moments. Objective To compare the postprandial hyperglycemia prevalence between different intensities of RE sessions in women with T2DM. Methods Twelve women with T2DM (55.2 ± 4.0 years; 70.1 ± 11.4 kg; 155.7 ± 3.3 cm; Diabetes: 5.7 ± 3.7 years) participated in a randomized order of experimental interventions, as follows: a) Control sessions without RE on day one (CONT40%1RM or CONT80%1RM) followed by; b) RE sessions (40%1RM or 80%1RM) on day two. The RE sessions were performed from 3 circuits with 7 exercises lasting 40min (08:20–09:00 a.m.) each (40%1RM - 16 reps or 80%1RM - 08 reps). Continuous glucose monitoring occurred every 5min for 24h post-intervention. The prevalence of hyperglycemia (glucose concentration >160 mg.dL $^{-1}$) was analyzed in the postprandial time of breakfast (08:00–12:00h), lunch (13:00–18:00h) and dinner (19:00–23:00h). Results The glucose concentration was reduced in 24h ($p < 0.05$) after 40%1RM session (142.6 ± 26.1 mg.dL $^{-1}$) vs. CONT40%1RM (194.3 ± 17.9 mg.dL $^{-1}$), CONT80%1RM (186.5 ± 26.4 mg.dL $^{-1}$) and 80%1RM (190.2 ± 43.3 mg.dL $^{-1}$). Lower prevalence of hyperglycemia ($p < 0.05$) in postprandial moments was found in the 40%1RM session vs. CONT40%1RM, CONT80%1RM and 80%1RM after breakfast (35.4 ± 22.5 % vs. 100.0 ± 0.0 %, 91.7 ± 22.2 % and 85.4 ± 29.1 %, respectively), lunch (28.3 ± 41.3 % vs. 98.3 ± 5.8 %, 88.3 ± 28.9 % and 73.3 ± 42.1 %, respectively) and dinner (6.3 ± 11.3 % vs. 81.3 ± 18.8 %, 85.4 ± 19.8 % and 70.8 ± 38.2 %, respectively). Discussion The reduction mechanism of postprandial hyperglycemia is possibly associated with the muscular contraction of AMP kinase signaling, which can promote GLUT4 translocation and glucose uptake (Richter & Hargreaves, 2013). It is speculated that the lack of response of high intensity RE at the postprandial moments may be due to an exponential increase of counter regulatory hormones (Kjaer et al., 1990). Conclusion A single low intensity RE session reduced the prevalence of postprandial hyperglycemia at moments of 24 hours of women with T2DM. References Manders RJF, Van Dijk JWM, Van Loon LJC. DISSIMILARITY IN PERIODIC FLUCTUATION AND SEASONAL VARIATION IN PHYSICAL GROWTH

TANAKA, H., FUJII, K., SAITO, Y., SAKAI, T.

Ryutsu Keizai University, AIT (Graduate School of Business administration and Computer Science, Aichi Institute of Technology, Toyota, Japan), Nagoya Zokei University of Art & Design, Chubu University

Introduction Fujii et al. (2007) advocated periodic fluctuation in height growth during preschool. In other words, the variation is not from the environmental factor of season; rather, height growth is achieved with periodic variations due to genetic factors. Based on this logic, wavelet interpolation was applied to observed data values measured three times a year in this study to investigate the periodic fluctuations in height and weight growth in elementary school children, and an attempt was made to verify the periodic fluctuations from the behavior of the derived velocity curve. Methods : The longitudinal time series information on subjects' height and weight were measured three times a year from the first to sixth grades. The data used in the analysis were for 17 boys and 11 girls. < Analytical procedure>: WIM (Wavelet Interpolation Method) was applied to longitudinal growth data consisting of attributes and organs. A cross correlation function was applied to the measured developmental indicators found by WIM and the velocity curve values. Results The results showed that the height growth pattern is essentially achieved with periodic fluctuations, and that there are seasonal stimulating phenomena within that periodicity. If this growth mechanism also applies to body weight, growth in body weight would occur together with increases in height, but with additional seasonal stimulating effects weight would be affected not only by genetic factors as height is, but also by seasonal environmental factors. Discussion It may be that the height growth pattern is essentially achieved by periodic fluctuations, with a seasonal acceleration phenomenon acting in this periodicity. If this growth mechanism functions for weight, growth in weight would accompany increases in height. However, since there is an additional seasonal stimulatory effect there are not only genetic factors as in height growth but also effects from seasonal environmental factors. From this study, however, we cannot comment any further on weight growth. References Fujii K, and Matsuura Y. RELATIONSHIP BETWEEN LOWER EXTREMITY RANGE OF MOTION, MUSCLE STRENGTH, AND PHYSICAL PERFORMANCE IN ELDERLY INDIVIDUALS

JUNG, H.1, TAKEUCHI, R.2, YAMASAKI, M.1

1:hiroshima university, 2:Osaka University of Health and Sport Sciences

Introduction Reduced lower extremity range of motion (ROM) and muscle strength were significantly correlated with functional disability in older individuals who are dependent for one or more activity daily living (Beissner et al., 2000). Therefore, the purpose of this study was to determine the extent to which the lower extremity ROM and muscle strength are associated with physical performance tests in older people. **Methods** One hundred thirteen community-dwelling elderly individuals (mean age \pm SD, 71.0 \pm 4.8 years; age range, 65–87 years) were recruited for this study. Active ROM for 7 lower extremity (hip flexion, hip extension, knee flexion, internal and external hip rotation, ankle dorsiflexion, and ankle plantar flexion) and 2 Muscle strengths (knee extension and flexion) were measured. Physical performance tests (Functional Reach Test, 5-m Gait Test, Four Square Step Test, Timed Up and Go Test, and Five Times Sit-to-Stand Test) were assessed. We conducted the principal component analysis to extract the physical performance scores from the five physical performance tests. To establish the influence of lower extremity range of motion and muscle strength on the physical performance, stepwise multiple regression analyses were constructed using physical performance measures and physical performance scores as the dependent variables. **Results** Most of the lower extremity ROM and muscle strength measures were consistently associated with physical performance tests ($r = 0.22$ to 0.56). The physical performance scores were obtained by principal component analysis using the five physical performance tests and accounted for 65.2% of the variance. Stepwise regression models for the physical performance scores revealed that hip extension and ankle plantar flexion ROM and knee extension strength were significant predictors of physical performance. This regression model explained 41% of the variance. **Discussion** The findings of this study demonstrated that lower extremity ROM and muscle strength were significantly associated with most physical performance tests using the lower limbs in adults aged ≥ 65 years. Thus, lower extremity ROM and muscle strength improvement can provide protection against the onset of restricted physical performance capacity, leading to functional disability. **References** Beissner KL, Collins JE, Holmes H. Muscle force and range of motion as predictors of function in older adults. *Phys Ther* 80:556–63, 2000.

ASSOCIATIONS AMONG NEIGHBOURHOOD ENVIRONMENT, PHYSICAL ACTIVITY, AND QUALITY OF LIFE: AN ECOLOGICAL STRUCTURAL MODEL IN ADULTS

KARTEROLIOTIS, K., THEODOROPOULOU, E.

National and Kapodistrian University of Athens

Introduction Over the last years, there has been an increased interest in investigating mediators of the Physical Activity (PA) and Quality of Life (QoL) association. In particular, PA has been found to promote QoL through the intermediary effects of exercise self-efficacy, and physical (PCS) and psychological (MCS) health. In addition, neighbourhood environment has been positively associated with PA, which in turn has improved PCS, MCS, and QoL. However, the aforementioned concepts haven't been examined within the context of the same theoretical model so far. The current study assessed an ecological model of neighbourhood environment, and QoL through the mediating effects of family and friend support for PA, exercise self-efficacy, PA, PCS, and MCS. The proposed model was separately examined for each one of the following PA indexes: walking PA, moderate PA, vigorous PA, and total PA. **Methods** 684 physically active adults ($M=39.16$, $SD=13.52$ years), living in Athens, Greece, completed a series of valid and reliable questionnaires measuring PA, QoL, exercise self-efficacy, PCS, MCS, neighbourhood environment, and family and friend support for PA. Structural equation modeling utilizing maximum likelihood estimation was conducted to assess the fit of the structural models. Results The ecological models proved to be of appropriate fit (PAwalking: CFI=0.960, GFI=0.926, RMSEA=0.036 / PAmoderate: CFI=0.961, GFI=0.926, RMSEA=0.035 / PAvigorous: CFI=0.957, GFI=0.923, RMSEA=0.037 / PATotal: CFI=0.958, GFI=0.924, RMSEA=0.037). The models accounted for 14%-16% of the variance in QoL. Within the models, neighbourhood environment positively influenced QoL through the intermediary effects of family and friend support for PA, exercise self-efficacy, PA, PCS, and MCS. Further, the association between exercise self-efficacy and PA was reciprocal, whereas MCS had the highest positive effect on QoL. These findings were verified for the four PA indexes. **Discussion** The findings demonstrated the role of neighbourhood environment in enhancing PA, and QoL. Further, the most important mediators in the examined models were exercise self-efficacy, MCS, and PA. A key feature of the study was the investigation of the ecological model for each one of the four examined PA indexes. No such study has been carried out until now in the literature. Future studies should be carried out applying longitudinal data for a better understanding of these associations over time. **References** Craig CL et al. (2003). *Med Sci Sports Exerc* 35:1381-95. DIFFERENCES IN THE REASON FOR DIETING BETWEEN GENDERS AND JAPANESE AND ASIAN OVERSEAS STUDENTS

SAKAGUCHI, H.1, CHOI, T.2, HAN, H.2, HONG, T.2, KOO, K.3, NAM, Y.4, IKEDA, T.5, AOYAGI, O.6

1: JUE (Japan), 2: JNU (Korea), 3: CNU (Korea), 4: DWU (Korea), 5: FPU (Japan), 6: FU (Japan)

Introduction Recently, more young people are devoting themselves to unnecessary dieting because of their strong desire to be slim, and this is becoming a public health concern. Why do young people diet? The reasons can be different between men and women and between countries with different cultural norms and ways of thinking regarding the body and health. This study aimed to investigate the differences in the reason for dieting between Japanese students (J-students) and Asian overseas students (O-students) by gender. **Methods** A questionnaire survey based on Nishioka et al. (1993) consisting of 27 items on the reason for dieting, such as "in order to dress up," "for good health" and "because my friends are dieting," was conducted in January 2015. Participants were 1003 J- and O-students at N-university in Japan. The 463 students (301 O-students and 162 J-students; 293 males and 170 females) who indicated that they had previous dieting experience were included in the analyses. Responses were given on a five-point scale ranging from "completely agree" to "completely disagree." Factor analysis with principle factor solution and normal varimax criterion was applied and then factor scores were computed using the regression method based on the derived factor loadings. T-tests were conducted in order to statistically test the difference between the two sets of means of J- and O-students by gender. **Results** Five factors with eigenvalues of 1.0 or greater were extracted and interpreted as follows: "factor 1 (F1), influence from friends and mass media," "F2, self-awareness," "F3, for good health," "F4, economic and convenient reasons" and "F5, to improve one's looks." In the analysis of gender differences combining J- and O-students, a significant difference at the 5% level was found in F4, showing that more female students chose this as a reason for dieting than male students. Significantly more male students agreed to items related to F1, F2 and F5 as reasons for dieting. As a consequence of

examining the difference between J- and O-students by gender, among male students, significantly more J-students agreed with items related to F1 as the reason for dieting, but O-students tended to agree with items related to F3. Among females, J-students dieted because of F4 whereas O-students dieted because of F5. That is, among males, more O-students dieted due to internal and substantial reasoning, but J-students dieted due to external factors such as suggestions from others or the mass media. On the other hand, among females, J-students dieted for economic reasons but O-students want to look cute or good.

EFFECTS OF INTERACTIVE VIDEO GAMES ON BRAIN AND CARDIOVASCULAR RESPONSES IN ELDERLY

WIDJAJA, W.

College of Sports Science and Technology

Introduction Although physical activity is important for improving cardiovascular and muscle strengths, there is growing interest in study of effect of physical activity on the brain function, especially in elderly. In recent years, an interactive video game is very popular in adults and adolescents. It is a virtual-reality based game in which body movement is used to control the game which is displayed on a television. Since it requires body movements, interactive video games can be developed to promote health, fitness and happiness. The aim of this study was to investigate the effect of interactive video game on the brain and cardiovascular functions in the elderly. Methods Ten males and ten females, aged 55-70 years old participated in this study. They were divided into two groups: sedentary (SW) and active (AW) groups. On the experimental day, their brain wave activities were measured by EEG with closed eye condition for 5 minutes at pre and post exercises. The cardiovascular variables such as HR, SV and EF were measured by non-invasive cardiovascular technique (PhysioFlow) throughout experiment. The participants played Wii games (Nintendo) at 50-70% of the maximum heart rate during warming up for 10 minutes and exercise for 20 minutes. The experimental data between the groups and within groups were compared by using unpaired t-test and paired t-test, respectively. Results The results showed that the amplitudes of theta and alpha waves in AW and SW groups did not change significantly when they were compared within the groups. Whereas the percent change of beta wave in AW and SW groups increased by 5.47% and 6.63%, respectively. However, theta/beta ratio in both groups were not significantly different. HR during exercise by Wii game in SW increased significantly and was higher than that of AW. SV and EF in AW were higher significantly than that in SW group at rest, during exercise and recovery periods. Discussion The effects of exercise on cortical activity in cerebral cortex which correlates with the arousal and increase in blood flows to the brain may caused the increase of the beta wave in SW more than that in AW after exercise. It is clear that active person will have higher performance especially in cardiovascular responses during exercise than the sedentary person. ANNUAL TRENDS DUE TO THE EFFECTS OF THE GREAT EAST JAPAN EARTHQUAKE TO THE PHYSICAL FITNESS OF UNIVERSITY STUDENTS

WATANABE, T.1, FUJII, K.2, SAKAI, T.3

1:*The University of Aizu (Japan)*, 2:*AIT (Graduate School of Business administration and Computer Science, Aichi Institute of Technology, Toyota, Japan)*, 3:*Hamamatsu Gakuin University (Japan)*

Introduction In Fukushima Prefecture, long outdoor activities are restricted because of the effects of the nuclear disaster at Tokyo Electric Power Company's Fukushima Daiichi Plant that occurred with the Great East Japan Earthquake. In this study we investigated the effects of earthquake on university students in Fukushima Prefecture from changes over time in the physical fitness, as well as the level of accumulated body fat based on differences in morphological properties. Methods The subjects were about 1,000 male students who started university from the years of 2004 to 2015. Considering this background, we calculated the statistics over time for physique, body composition, and motor performance. Results We adopted analysis of variance (ANOVA) from the years of 2004 to 2015. In first semester, grip strength, side step, standing long jump, significant difference were observed($p<0.05$). In second semester, weight, BMI, grip strength, 20m shuttle run, side step, standing long jump, significant difference were observed($p<0.05$). In grip strength, certain trends were observed. In annual trends of grip strength, we have applied cubic least squares approximation polynomial. As shown cubic polynomial, gradually began to decrease from around 2006, in 2012 and 2013 to become the most recessed point, the upward trend has been shown again. Regarding annual trend of fat accumulation rate by difference of morphological quality based on evaluation of regression polynomial of %fat for BMI, it was basically no difference in compared with first semester and second semester from 2004 to 2015. Discussion In this study, effects on physique were not observed. In motor performance, although significant difference was observed, a clear trend was not observed. The results of an analysis of variance showed a significant difference in grip strength. Assessing annual trends in grip strength from a least squares approximation polynomial, it was shown that grip strength decreased until 2012 and that currently there is a slightly rising trend. In present study, the results did not show the clear effects of earthquake on university students in Fukushima Prefecture. In the future, it is considered that there is a need for further analysis study were classified subject in detail. References Fujii K, et al (2009) Comparison between Japanese and Korean School Students in Physical Fitness Based on Difference of Morphological Quality, The journal of Education and Health Science, 55, 145-154. twatanab@jc.u-aizu.ac.jp

RELATIONSHIPS BETWEEN DIETING METHOD AND THE FACTORS OF GENDER DIFFERENCE AND NUTRITIONAL KNOWLEDGE AMONG ATHLETES AND DIETITIANS

MIYATA, M.1, YAITA, A.1, AOYAGI, O.2, CHOI, T.3, HAN, N.3, HONG, T.3, NAM, Y.4, KOO, K.5

1:*KKU (Japan)*, 2:*FU (Japan)*, 3:*JNU (Korea)*, 4:*DWU (Korea)*, 5:*CNU (Korea)*

Introduction Athletes are required to maintain their optimal weight to perform well in their sport. However, it is thought that gender differences exist in the methods used to maintain body weight. Furthermore, when an individual has insufficient nutrition knowledge, it is possible that they will use inadequate dieting methods and be overly conscious of the effects of dieting. This study aimed to examine gender differences and the appropriateness of dieting methods among athletes by comparing them with students in the Department of Food Science and Nutrition, who were the same age as the athletes and thought to have sufficient nutritional knowledge. Methods Referring to Matsumoto et al. (1997), a questionnaire survey comprised of 22 items was conducted with 518 sports-related faculty students at K-university (365 males and 153 females) and 137 nutrition-related faculty students at F-university (only female) in Japan in April 2015. Subjects were asked to choose one of the following responses: "I am doing it now (now)", "I did it in the past (past)", and "I have never done it and I have no interest in it (never)." The answers were tallied into a cross table by male students enrolled in a sports-related

faculty (male athletes), female students enrolled in a sports-related faculty (female athletes), and female students enrolled in a food science and nutrition-related faculty (female dietitian). The relational tendency was investigated based on cells showing a significantly greater adjusted residual. Results Twelve items indicated the pattern of female athletes having a significant adjusted residual in "now" and male athletes in "never." Another two items showed the pattern of combinations of female athletes and "past" and male athletes and "never." In short, participating in sports forced female athletes to diet, but this was not the case for male athletes. The fact that female dietitians answered "past" in four items such as "I care a lot about what I eat." led us to believe that their dieting methods require strong self-awareness and willpower. Furthermore, in "I take laxatives in order to lose weight.", female dietitians showed a distinct negative attitude by choosing "never"; in contrast, female athletes demonstrated a positive attitude by choosing "past." Although people who are well informed about nutrition avoid inappropriate dieting methods, female athletes, who possibly did not have the necessary understanding of nutrition, used improper methods, because of pressure to reduce their body weight.

SHORT TERM SECULAR CHANGE IN BODY SIZE AND PHYSICAL FITNESS OF YOUTH 7-15 YEARS IN SOUTHWESTERN POLAND: 2001-2002 AND 2010-2011

IGNASIAK, Z., ŚLAWIŃSKA, T., MALINA, R.M., POKRYWKA, J.

University School of Physical Education

Short term secular change in body size and physical fitness of Polish youth 7-15 years of age resident in an industrial region of Lower Silesia in southwestern Poland were considered across two surveys, 2001-2002 and 2010-2011. Subjects were students in the same schools in both surveys 1892 boys and 1992 girls in the first and 1237 boys and 1236 girls in the second. In addition to height and weight, performances on six Eurofit fitness tests were measured. Height, weight and BMI increased significantly across surveys. Statistically controlling for secular gains in height and weight, only grip strength and agility/speed shuttle run improved significantly between surveys across three age groups (7-9, 10-12, 13-15 years), while sit-ups, the sit and reach and speed of upper limb movement declined between surveys, except for sit-ups in boys 13-15 years. The standing long jump improved among girls 7-9 and 10-12 years and boys in the three ages groups, though not all differences were significant; however, the jumping performance of adolescent girls 13-15 years declined significantly. In conclusion, comparisons across one decade showed a secular increase in body size, but variable changes in several physical fitness items.

EXAMINING WEIGHT CONTROL AND DIET BEHAVIOR AMONG UNIVERSITY STUDENTS IN JAPAN AND SOUTH KOREA

IKEDA, T.O.1, IKEDA, T.A.2, YAITA, A.3, SAKAGUCHI, H.4, ITOH, H.5, ANNOURA, T.6, AOYAGI, O.5, HONG, T.7, HAN, N.8, CHOI, T.8, NAM, Y.9, KOO, K.10

1: Nishi-Kyushu University, 2: Fukuoka Prefectural University, 3: Kyushu-kyoritsu University, 4: Japan University of Economics, 5: Fukuoka University, 6: Fukuoka University Graduate School, 7: Kyung S

Introduction Among Japanese youths, the rate of those controlling their own weight is higher among females than it is among males (Ikeda & Ikeda, 2004). Health problems derived from controlling one's weight despite being of an appropriate weight are common among Japanese youths generally (Hand & Oguro, 2006). Similarly in South Korea, weight control has been linked with health-damaging eating disorders (Woo, 2014). The purpose of this study was to investigate the nature of weight control and diet behavior among university students in Japan and South Korea. Methods The research participants were 1,810 students in Japan and South Korea. All the participants were surveyed on whether they were practicing or not practicing weight control. Those controlling their weight completed the Scale of Diet Behavior (SDB) (Matsumoto et al., 1997). A chi-square test was applied to investigate the relationship between practicing/not practicing weight control, gender, and country. A two-way layout ANOVA with general linear model was applied to the factor scores on the SDB in order to find differences pertaining to gender and nationality. Results The ratios of female students practicing weight control to male students in both countries were as follows: JPN, M: 18.4%, F: 58.7%, chi-square =151.892; KOR, M: 42.3%, F: 61.1%, chi-square =32.601. Among male students, weight control was more prevalent among Koreans while, among female students, there was no significant difference between the two countries (chi-square =59.682). Factor analysis extracted two factors pertaining to diet behavior; one, known as the 'structural diet: SD' being healthy, and the other being unhealthy ('unstructured diet: UD'). The ANOVA for SD showed that there was a significant difference relating to gender ($F [1, 803] = 39.4, M < F$) but not relating to nationality. In UD, there was interaction between gender and nationality. In a multiple comparison test, female UD was greater than male UD in Korea ($t [475] = -3.3$) and, among females, Korean UD was greater than Japanese UD ($t [544] = -6.1$). Discussion Far more females control their own weight than males in both Japan and South Korea. In terms of their diet behavior, more female students are SD than males. In this respect there is little difference between Japan and South Korea. Nevertheless, more Korean females are UD than Japanese females and/or Korean males. The results of this study revealed the characteristics of weight control and diet behavior and show the importance of health education for Japanese and Korean youths. EFFECTS OF 4 WEEKS OF HORSEBACK RIDING ON ANXIETY, DEPRESSION, SELF-ESTEEM IN CHILDREN WITH ADHD

SEO, D.I., LEE, S.Y., SO, W.Y.

Dongguk University, Korea National University of Transportation

Introduction: Attention-deficit hyperactivity disorder (ADHD) is a common neurodevelopmental disorder that characterized by developmentally inappropriate levels of inattention, overactivity, distractibility, and impulsiveness, which manifest during childhood. Horseback riding is a physical therapy intervention that aims to improve postural stability, increase of sensory inputs, decrease muscle tone, and improve postural muscle activities. Until now no research has been published on horseback riding effective in improving the ADHD symptoms. PURPOSE: To determine the effects of 4 weeks of horseback riding on anxiety, depression, self-esteem in children with ADHD. METHODS: The subjects comprised a convenience sample of 10 children aged 10-12 years with ADHD and 10 children without ADHD. Horseback riding sessions were performed 2 times (40 minutes/day) per week for 4 weeks. Before and after the horseback riding program, we measured the children's anxiety, depression, self-esteem. The pre- and post-tests scores were analyzed with repeated-measures ANOVA. RESULTS: After the participation of the 4 weeks of horseback riding program, anxiety ($p < .05$), and depression ($p < .01$) were significantly improved in ADHD group. CONCLUSION: These results indicate that the 4 weeks of horseback riding program used in this study was very effective for producing significant improvements to anxiety and depression in children with ADHD.

PHYSICAL PERFORMANCE AND THE DIURNAL CYCLE OF CORTISOL IN OLDER ADULTS WITH AND WITHOUT COGNITIVE IMPAIRMENT

TORTOSA-MARTÍNEZ, J., CAUS, N., CORTELL-TORMO, J.M., MANCHADO-LOPEZ, C., MARTÍNEZ-PELEGRIN, B., ROMERO-NARANJO, J.

University of Alicante

Introduction: Chronic stress and aging can lead to dysfunction of the hypothalamic–pituitary–adrenal (HPA) axis, leading to aberrant circadian patterns of cortisol secretion and a cascade of negative downstream events, including increased risk of developing Alzheimer's disease. There is evidence showing that physical activity can have restorative effects on the stress neuroendocrine system, although results are not always conclusive. The circadian pattern of cortisol secretion is complex and it has not been contemplated in many studies, which may explain some of the inconsistencies in the literature. **Methods:** The present study examined the diurnal cycle of salivary cortisol (Waking, 30 minutes post waking, 12:00, 17:00, 21:00) and physical performance (Six minute walk test; Walking speed; Timed get up and go test; Chair stand test) in a sample of older adults without cognitive impairment ($n=45$) and with Amnestic Mild Cognitive Impairment ($n=40$). The Cortisol Awakening Response (CAR), the drop between the peak of the CAR and 12:00 levels, and the mean level of cortisol after the CAR (mean of samples at 12:00, 17:00 and 21:00) were calculated. **Results:** Correlation analysis showed that lower mean day cortisol levels were associated with better physical performance as measured in the speed of walking ($r=0.405$; $p<0.001$), the Six-minute walk test ($r=-0.267$; $p<0.05$), and the Timed get up and go test ($r=0.286$; $p<0.05$). When a regression model was applied controlling for age and gender, the three test remained as predictive variables for the mean day cortisol ($p<0.01$), with speed of walking being the stronger predictor of all three tests. **Discussion:** Two explaining mechanisms can be suggested based on these findings. First, the HPA axis and the diurnal cycle of cortisol might have a role in physical decline (Arsenault-Lapierre, Chertkow & Lupien, 2010). Second, physical activity and changes in physical performance may induce alterations in the HPA axis and the diurnal cycle of cortisol (Kumari et al. 2010). **References:** Arsenault-Lapierre G, Chertkow H, Lupien S. CHANGES IN OXIDATIVE STRESS MARKERS OF MUSCLE INJURY IN RESPONSE TO CROSSFIT TRAINING

SADOWSKA-KRĘPA, E., DOMASZEWSKI, P., POKORA, I., KŁAPCIŃSKA, B.

the Jerzy Kukuczka Academy of Physical Education in Katowice

Introduction CrossFit training is associated with substantially enhanced production of free radicals and other reactive oxygen and nitrogen species (ROS/RNS), widely regarded as factors that may contribute to exercise-induced muscle damage (Kliszczewicz et al., 2015). The purpose of this study was to assess the oxidative stress responses to a graded maximal cycling test following a 6-week CrossFit training. **Methods** Nine apparently healthy male volunteers (aged 24.1 ± 2.7 years, $V02\text{max } 47.5\pm5.0 \text{ ml/min/kg}$) involved in CrossFit training performed a graded cycle exercise test to volitional fatigue twice, i.e. before starting training (1st trial) and then once more after 6 weeks of CrossFit training (2nd trial). Activities of creatine kinase (CK), lactate dehydrogenase (LDH), aspartate aminotransferase (AST), as well as malondialdehyde (MDA) and ferric reducing ability of plasma (FRAP) were estimated in blood plasma samples at rest, immediately post-test and after 1 hour of recovery. **Results** A graded maximal cycling test induced a significant increase ($P<0.05$) in post-test activities in LDH and AST in the 1st trial, as well as a significant rise in post – test activities of CK, LDH, AST and MDA level in the 2nd trial. Six weeks of CrossFit training led to significant increase ($P<0.05$) in pre- test activities of CK, LDH and MDA content compared to values recorded during the 1st trial, whereas both pre – and post - test FRAP levels were only not significantly higher from baseline levels. **Discussion** Exercise-induced oxidative stress is considered the main cause of tissue damage consequent to peroxidation of membrane lipids, leading to increase in the permeability of cell membranes, which results in the leakage of tissue enzymes into the blood stream. On the other hand, ROS generated during muscle contraction play an important signaling role in muscle adaptation to exercise (Powers et al., 2011). Our findings indicating that in spite of some enhancement of antioxidant defense capacities evidenced by FRAP, a 6-week CrossFit training led to marked increase in muscle damage markers kept, however, within the reference limits for highly active athletes (Mougios, 2007), reflect the effects of inadequate recovery time between individual training workouts. **References** Kliszczewicz B, Quindry CJ, Blessing LD et al. IMPROVEMENT IN SLEEP, TASK EXECUTION, AND FUNCTIONING OF THE AUTONOMIC NERVOUS SYSTEM OF CHILDREN DURING LONG-DURATION CAMPING <30 NIGHTS AND 31 DAYS>

NOI, S., SHIKANO, A.

Nippon Sport Science University

Introduction Currently, life in Japan is too competitive, suppressive, convenient, and comfortable; this lifestyle can affect the sleep and progress of mind of children and lead to poor physical fitness. Activities such as camping are expected to solve these problems. Therefore, the aim of this study was to examine the changes in sleep, task execution, and functioning of the autonomic nervous system of children during long-duration camping. **Methods** This study, conducted from 2007–2015, included 180 children (age, 10.6 ± 1.2 years; 148 boys and 32 girls) who participated in a long-duration summer camp (30 nights and 31 days). In this study, a salivary melatonin concentration measurement survey in 2011, go/no-go task surveys in 2007–2015, and a cold pressor test (CPT) surveys in 2007–2012 were performed. Saliva for melatonin concentration measurement survey was collected at 5 instances at night (9:30 pm) and in the morning (6:30 am) on the 9th and 10th day before camping; 2nd and 3rd day, 16th and 17th day, and the 29th and 30th day during camping; 30th and 31st day after camping. The go/no-go task and the CPT, in which the fingertip of the right hand was stimulated with cold water at 4°C , were carried out in the early, middle, and final stage of each camping period. **Results** The salivary melatonin concentration during camping was increased at night and decreased in the morning. However, after camping, the salivary melatonin concentration returned to the initial level. Conversely, the false reaction numbers to go/no-go task and the vasoconstrictor response to cold water had decreased in the middle stage compared to in the early stage, and in the final stage compared to in the middle stage during camping. **Discussion** As well known, exposure to light at night suppresses melatonin secretion in humans (Lewy et al., 1980), while exposure to light during the day

increases nocturnal melatonin secretion (Mishima et al., 2001). Additionally, other studies have also suggested that doing physical exercise during daytime (Miyazaki et al., 2001) and maintaining regular mealtimes (Hara et al., 2001) may affect the biological rhythm. Such a lifestyle can be maintained during camping. Thus, we suggest that the lifestyle in a camp improves one's biological rhythm and has a good influence on task execution and autonomic nervous system functioning. In conclusion, we suggest that incorporating activities such as camping into daily living of children should be a future practice to improve the spirit of a child. References Hara R et al. CANCER SURVIVORS' PHYSICAL ACTIVITY AND CHRONIC COMORBIDITY CONDITIONS: KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2008-2011

LEE, H., KIM, B., KANG, S., SEO, J.

Sangmyung University

Introduction Research shows that chronic comorbidity affects poor cancer survival (Sogaard et al., 2013). Nevertheless, cancer survivors are also at risk for developing these conditions (Edgington & Morgan, 2011). Therefore, this study was purposed to investigate the associations between physical activity and comorbidity conditions among cancer survivors in Korea. Methods Subsamples of cancer survivors (N=611) from 2008-2011 Korea National Health and Nutrition Examination Survey data were analyzed. Using IPAQ, weekly hours spent in vigorous (VPA) and moderate physical activity (MPA), and walking, and muscular strengthening activity adherence (2+ days/week) were measured. Chronic comorbidity conditions as dependent variables were dyslipidemia, hypertension, obesity (BMI>25), diabetes, osteopenia/osteoporosis, depression and quality of life (EQ-5D). Age-group-specific (middle-aged: 30-64 years; older adults: 65+ years old) regression analyses were performed for each dependent variables, controlling for age, sex, caloric intake, and years since cancer diagnosis as covariates. Results In middle-age cancer survivors, VPA and was inversely associated with the incidence of dyslipidemia (OR=.92, p=.012). Muscular strengthening activity was positively associated with quality of life ($r=3.55$, $p=.038$). On the contrary, middle-aged adult cancer survivors who spent more hours in MPA were more likely to be obese (OR=1.05, $p=.009$). Among older adults, time spent in walking was associated with better quality of life ($r=.40$, $p=.029$). In contrast, muscular strengthening activity was positively associated with incidence of dyslipidemia (OR=2.98, $p=.035$) and diabetes (OR=4.02, $p=.009$). Discussion Studies consistently supports importance of physical activity in preventing chronic diseases (PAGAC, 2008). The current study largely supports that physical activity can play positive roles in preventing chronic conditions among cancer survivors, too. Because MPA among middle-aged survivors and muscle strengthening activities among older survivors were associated with higher incidence rated of obesity, dyslipidemia, and diabetes, nevertheless, future studies should investigate potential confounding factors and cause-and-effect associations. EFFECT INSPECTION OF "WALK" AMONG CHILDREN

SHIKANO, A., MASUDA, S., NOI, S.

Nippon Sport Science University

Introduction The increasing incidences of children with sleep and concentration problems are of concern in Japan. In this study, we confirmed that melatonin rhythm was improved during attendance of a long-duration camping (30 nights and 31 days) (Noi et al., 2009; Noi et al., 2013). However, it is not easy to implement the long-duration camping in a real-world setting. Therefore, the challenge has been to determine which principles of the long-duration camping are most effective in real-world settings. In this context, the routine walk practiced in the nursery has recently attracted attention. This study assessed the effects of routine walking on sleep and execution function in infants. Methods This study included 53 infants who routinely walked for around an hour. The survey was performed from October to November 2014. Saliva samples were collected at night (21:00 p.m.) and the next morning (6:30 a.m.) on both "walk days" and "no-walk days." Additionally, the numbers of false reactions to a go/no-go task were collected at same time on "walk days" and "no-walk days." We compared the melatonin concentration and the false reaction numbers by go/no-go task of "walk days" and "no-walk days." Results Comparison of saliva melatonin concentrations by two-way repeated analysis of variation revealed an interaction between walking and time. On the other hand, comparison of the numbers of false reactions to the go/no-go task by repeated t-tests showed significantly lower numbers for "walk days" than for "no-walk days." Discussion Exposure to light (Mishima et al., 2001) and physical exercise (Miyazaki et al., 2001) during the daytime is well known to increase nocturnal melatonin concentrations. In addition, the results of our study confirm that physical activity improves execution functions (Best, 2010.) Thus, the result of this study supports the results of these precedence studies. Based on these findings, we conclude that routine walking in the nursery may be an effective solution to sleep and execution function problems among Japanese children. (2009) Jpn J Hum Growth and Dev Res, 41, 36-43 (in Japanese with English abstract) Noi S et al. (2013) Jpn J Hum Growth and Dev Res, 58, 25-33 (in Japanese with English abstract)

THE ACTUAL CONDITIONS OF SLEEP, SUBJECTIVE FATIGUE, MOOD DYSREGULATION TENDENCY, AND INTERNET ADDICTION TENDENCY AMONG JUNIOR HIGH SCHOOL STUDENTS IN A CERTAIN AREA OF JAPAN

TANAKA, R., HISAKAWA, H., SHIKANO, A., NOI, S.

Nippon Sport Science University

Introduction In Japan, the health of children has long been a concern. In later years, anxiety about nightlife, fatigue, depression, and Internet addiction, in particular, increase. There are many reports about these situations. However, there are extremely few large-scale investigations carried out on the same target person and examining the actual situations and relations among those problems. Under such circumstances, the Setagaya Ward Board of Education and the Nippon Sport Science University constituted a consortium and are working to improve health promotion and children's physical fitness. As part of its activities, the present study was carried out to clarify the actual conditions of sleep, fatigue, mood dysregulation tendency, and Internet addiction tendency and their relations in all public junior high school students in Setagaya Ward, Tokyo. Methods Subjects were 9,628 1st to 3rd grade students (5,255 boys and 4,373 girls) from

all public junior high schools in Setagaya Ward. This study was carried in March, 2015. In this study, data about bedtime, wake-up time, sleep problems, subjective symptom of fatigue, mood dysregulation tendency, and Internet addiction tendency were collected using a self-completed questionnaire survey. Results Bedtime and wake-up time were slowed with the start of the school year. Sleep problems increased with advancing grades. Fatigue rose as grade increased in boys, but there was no change in girls. Mood dysregulation tendency increased in boys but decreased in girls as grade increased. The proportion of those with a tendency toward Internet addiction determined to be pathological use and maladaptive use increased with increasing grade. In addition, people with strong Internet dependence were found to have a tendency toward sleep problems of slow bedtime, frequent fatigue, and mood dysregulation. Discussion The results of this study showed a similar tendency of late sleeping as in another report (Japanese Society of School Health, 2014) in Japan in 2013. On the other hand, the Internet-dependent trend of the present study in people with strong sleep problems was supported by the results of previous study (Oka et al., 2008) that sleep routines worsen in bedrooms with electronic media. In Japan, the spread of electronic media can be expected to proceed in the future, and there is concern that sleep problems in children will continue to worsen. References Japanese Society of School Health (2014) Enterprise report on the health status surveillance among the child (in Japanese) Oka et al. (2008) Behav Sleep Med, 6, 220-233

ASSOCIATION BETWEEN SKELETAL MUSCLE MASS AND DEPRESSIVE SYMPTOMS IN JAPANESE COMMUNITY-DWELLING ELDERLY WOMEN : A CROSS-SECTIONAL STUDY.

IMAI, A.1,2, KURIHARA, T.2, SANADA, K.2

1: Seijo University (Aichi, Japan), 2: Ritsumeikan University (Shiga, Japan)

INTRODUCTION: Previous studies indicated that the depressive scores were associated with skeletal muscle mass (SMM) and/or sarcopenia in elderly men (Jenny et al., 2007; Ying et al., 2014). However it still remains unclear whether SMM associates with depressive symptoms as covariate of comprehensive analysis with objective physical activity. Therefore, we test the hypothesis that SMM associates with depressive symptoms as covariate of comprehensive analysis with objective physical activity. **PURPOSE:** The aim of the present study was to investigate whether SMM associates with depressive symptoms as covariate of comprehensive analysis with objective physical activity in elderly women. **METHODS:** This cross-sectional study involved a total of 153 healthy elderly woman aged 65 and over (mean age 74 ± 6 years) in Aichi prefecture, Japan. All measurements were performed at the community centers from August to September of 2015. This study was approved by the Seijo University ethics committee. All participants provided written informed consent. The SMM was measured by bioelectrical impedance analysis (BIA). Depressive symptoms was evaluated by 15-item Geriatric Depression Scale (GDS-15). All participants were divided into two groups (GDS-15 score of 6 or more; depressive symptoms group (D group), <6; non-depression symptoms (non-D group). We examined the relationship between height-adjusted appendicular SMM (ASM) and depressive symptoms using one-way ANCOVA, adjusted for age, economic conditions, lifestyle habit, social situation, and physical activity measured by accelerometer. All tests were two-sided and a P value of <0.05 was taken as statistically significant. **RESULTS:** In this study, 13.1% ($n=20$) of participants were categorized as the D group. After adjustment for all factors, height-adjusted ASM were significantly lower in the D group (5.73 ± 0.33 kg/m²) than in the non-D group (6.38 ± 0.83 kg/m²). **CONCLUSION:** Low height-adjusted ASM was associated with depressive symptoms independently various factors. These results suggest that increase in SMM may prevent depressive symptoms in elderly women. Future studies will need to assess the effect of exercise intervention on depressive symptoms in elderly women.

TRAINING EFFECT DURING THE POLARNIGHT IN DIFFERENT CHRONOTYPES

VITALE, J.A.1, WEYDAHL, A.2, BJOERKESET, E.2, CAMPARA, A.1,2, PANIZZA, G.1,2

1: University of Milan (Italy); 2: UiT The Arctic University of Norway (Alta, Norway)

Introduction In a previous study we have found that adults with different chronotypes have responded differently to exercise performed in day-light or darkness (Vitale, Calogiuri, & Weydahl, 2013). Above 70 dgr North, the sun is not above the horizon for about 8 weeks, giving the people living there very little daylight. The aim of this paper is to study the effect of training during the polar nights in relation to the individual's chronotype. To the best of our knowledge, no past studies investigated this topic. **Method** We used Horne and Östberg questionnaire to determine chronotype in 265 inhabitants wanting to participate. 10 M-, 10N- and 10 E-types were chosen to participate. The last week before the polar night, we found the participants' anaerobic lactic acid profile (AT) and their maximal oxygen consumption (VO₂ max) (test 1). During the polar night period the participants trained in a group one hour out-of-doors and one hour indoors each week in addition to every-day homework, like going outside at least 10 minutes and some flexibility, balance and strength exercise. The week after the polar night, the subjects were retested (test 2). Subjects that did not participate in training or test 2 were excluded in the further analyses. We run multiple regression analyses to check for a possible relationship between chronotype and the % of changes from test 1 to test 2. **Results** Fifteen subjects completed the study: 8 females and 7 males with mean age 37 years, BMI: 28. They were 3 E-types, 5 N-types and 7 M-types. Mean values at test 1: VO₂max: 36.9 ml/min x kg and HR at AT: 82% of HRmax. No significant relations were observed from multiple regression analyses looking at the % of changes in VO₂ max (R²: 0.07, p=0.369) and AT (R²: 0.02 p=0.61) and the MEQ scores of each subjects. The data for VO₂max and AT were normally distributed therefore we performed a paired t-test from test 1 to test 2 conditions for the whole group. We observed that the subjects increased significantly their VO₂ max (from 36.9 to 39.6 with a p=0.02). **Discussion** The increased VO₂max is expected since the subjects trained for several weeks nevertheless, this increase was significant only for E-types and N-types but not for M-types. We can hypothesized that M-types did not increase their VO₂ max because they were disadvantaged during the training period with darkness. We did not observe a real overall chronotype effect on test results performed after the period of polar nights. The group size is a limiting factor, it is advisable to continue the study to include more subjects. **References:** Vitale, J. A., Calogiuri, G., & Weydahl, A. (2013). Influence of chronotype on responses to a standardized, self-paced walking task in the morning vs afternoon: A pilot study 1. Perceptual & Motor Skills, 116(3), 1020-1028.

PHYSICAL ACTIVITY LEVEL AND ITS CORRELATES IN THE CROATIAN ADULT POPULATION

RAKOVAC, M.1, PEDIŠIĆ, Ž.2, HEIMER, S.1

1: Faculty of Kinesiology, University of Zagreb (Zagreb, Croatia), 2: Institute of Sport, Exercise and Active Living, Victoria University (Melbourne, Australia)

Introduction Understanding physical activity (PA) levels and its correlates can aid in planning PA promotion interventions. This is the first study to examine the PA level in the Croatian adult population by means of the EPIC-Norfolk Physical Activity Questionnaire (EPAQ2) – assessing past year's PA in different contexts. The aims of the study were: a) to determine the PA level (total and domain-specific) of the

adult Croatian population and b) to determine the relationship between total PA and selected socio-demographic, lifestyle, and health characteristics. Methods The sample consisted of 551 participants (58.6% females; age (mean \pm SD) 41 \pm 15 yrs (females) and 44 \pm 16 yrs (males)). Public health institutes across Croatian counties were requested to randomly select 10 primary care physicians, which were then instructed to recruit 10 of their adult patients to participate in this study. The participants filled out the EPAQ2 questionnaire and responded to a set of questions on potential correlates of PA (age, body mass index, household income, education, type of settlement, smoking habits, and self-perceived health). Total PA level and PA levels in four domains (work, commuting, home, recreation) were calculated and expressed in MET-hour/week. Results Total PA was significantly higher in females than in males (medians: 133.7 vs 114.8 MET-hour/week, Mann-Whitney U test p=0.002). Significant differences between sexes were observed for PA levels in home (females: 56.9, males: 22.6, p<0.001), recreation (females: 21.1, males: 6.82, p=0.001) and work domains (females: 32.8, males: 60.2, p<0.001). No difference between sexes was found for active transport, where most females and males reported no participation (p=0.076). Additionally, a multiple regression analysis showed that household income (p<0.001) and self-perceived health (p=0.028) are positively, while living in an urban area (p=0.001) is negatively related to total PA. Discussion Total PA level in both sexes was significantly higher than in previous Croatian studies, possibly due to methodological differences. According to the results on domain-specific PA levels and PA correlates, future public health initiatives should be directed toward promotion of PA in transport and leisure time contexts, and focused on low-income persons, suburban and urban areas, and people with poor health. THE DECREASE IN BLOOD CHOLESTEROL INDUCED BY NORDIC WALKING TRAINING IS MODULATED BY VITAMIN D SUPPLEMENTATION IN ELDERLY WOMEN

KORTAS, J.1, PRUSIK, K.1, SKROBOT, W.2, MIESZKOWSKI, J.3, KOCHANOWICZ, A.4, ANTOSIEWICZ, J.5, ZIEMANN, E.6

1, 2, 4, 5, 6Gdansk University of Physical Education and Sport, Gdansk, 3Kazimierz Wielki University, Bydgoszcz, Poland

Introduction Vitamin D3 deficiency and high blood cholesterol concentration is commonly observed conditions in modern society. Limited outdoor physical activity is considered to be a contributing factor, as vitamin D is synthesized in the skin from cholesterol. Some study showed that physical activity lowers blood cholesterol (Paoli et al., 2013) and plasma 25-hydroxyvitamin D (25-OH-D) is inversely associated with triglycerides and total cholesterol (Garcia-Bailo et al., 2013). The combined effect of exercise and vitamin D supplementation on blood lipid profile, however, has not been studied. Methods Here we investigated the effects of vitamin D3 supplementation (800 IU and 4000 IU) and 12 weeks of Nordic walking training on serum lipids in elderly women aged 67 \pm 7.8 yrs. The subjects were divided into two groups following the same training schedule, but different supplementation scheme: one received 800 IU/day (II), while the other received 4000 IU/day (III). Plasma, total triacylglycerol (TG), total cholesterol (TC), high-density lipoprotein (HDL-C) and low-density lipoprotein (LDL-C) cholesterol were determined pre- and post-intervention. The ratios of TC/HDL-C and LDL-C/HDL-C were also calculated. Results The applied training program and supplementation 4000 IU/day were found to have caused a significant decrease in TC 224 \pm 39 vs 199 \pm 35mg·dL $^{-1}$ (p<0.05) and HDL-C (73.8 \pm 16.3 vs 4.9 \pm 14.9mg·dL $^{-1}$). LDL-C values also dropped, yet the changes were not statistically significant. In comparison in group I a minor decrease in both TC and LDL did not account for a statistically significant change. Discussion The present study demonstrates, that regular Nordic walking training, when accompanied by vitamin D supplementation, induced a significant decrease in blood total cholesterol in elderly women. It is important to note that changes in HDL cholesterol were more pronounced compared to LDL. Previously published studies are partially in agreement with our data, as it has been shown that plasma 25-OH-D was inversely associated with triglycerides, total cholesterol, low-density lipoprotein cholesterol, and the ratio of total to high-density lipoprotein cholesterol. In conclusion, our data suggest that the effects of regular exercise on blood lipid profile depends on vitamin D3 concentration. AGE-ASSOCIATED CHANGES OF GROUND REACTION FORCE PARAMETERS DURING SIT-TO-STAND MOVEMENT IN 801 WOMEN AGED 18–89 YEARS

NAKATANI, T.1, TERADA, K.1, SHIRAISHI, A.1, NADAMOTO, M.2, MIURA, S.3, MURAKAMI, K.4, KAWATA, Y.4

1: Tenri University (Nara, Japan), 2: Poole Gakuin University (Osaka, Japan), 3: Kyoto Gakuen University (Kyoto, Japan), 4: Kokugakuin University (Kanagawa, Japan)

Introduction Physical functioning during daily activities, such as climbing stairs or rising from a chair, requires muscular strength and power. This ability declines with advancing age, with the loss of muscle mass and impaired neuromotor control (Martin et al., 2000). This study aimed to examine age-associated changes in vertical ground reaction force (GRF) during sit-to-stand (STS) movements in healthy Japanese women aged 18–89 years. Methods Eight hundred and one healthy women participated in this study and were divided into seven age groups as follows: 18–29 years (20s), 30–39 years (30s), 40–49 years (40s), 50–59 years (50s), 60–69 years (60s), 70–79 years (70s), and 80–89 years (80s). All participants could stand up from sitting on a chair without holding onto anything for support. Participants sat in an adjustable chair with their feet on a force plate, and stood as quickly as possible. The body weight overshoot (SUI), rate of rise in GRF (RFD), and reaction time (RT) parameters were measured during STS movement (Freming et al., 1991). Results The vertical GRF parameters during STS movement were inversely related with aging in healthy women. Correlation coefficients in the age-related GRF parameters were SUI ($r = -0.64$, $P < 0.05$), RFD ($r = -0.54$, $P < 0.05$), RFD/kg ($r = -0.62$, $P < 0.05$) and RT ($r = 0.30$, $P < 0.05$). SUI, RFD, and RFD/kg decreased rapidly already in the 30s and RT decreased slowly in the 70s. The oldest age group (80s) had lower SUI (18.4%), RFD (45.7%), RFD/kg (32.6%), and RT (32.4%) values when compared with the youngest group (20s). Percent changes for SUI, RFD, RFD/kg, and RT were 3.2%, 8.3%, 6.3%, and 6.6% per decade, respectively. Discussion The main finding of this study is that the age-associated decline in GRF parameters during STS movement seems to accelerate with advancing age in healthy women. The percent changes for explosive force production or anaerobic power were 10%–12% per decade in healthy adults (Izuquierdo et al., 1999; Kostka et al., 2009). In this study, the age-associated changes of SUI, RFD, and RFD/kg per decade during STS movement were smaller than those in previous studies. PHYSICAL FITNESS OF LITHUANIAN PRIMARY SCHOOL CHILDREN. PILOT STUDY

CESNAITIENE, V.1, EMELJANOVAS, A.1, MIEZIENE, B.1, TUMYNAITE, L.1, FJØRTOFT, I., KJØNNIKSEN, L.

Lithuanian Sports University

Introduction At present, studies have shown that despite the physical activity recommendations and greater investment in the promotion of children's physical activity, there is still not enough attention paid to testing children's physical fitness. In particular, there is a lack of analysis of younger school-age children's physical fitness and its influencing factors. It is well known that underdeveloped physical abilities of children have a negative impact on their health and well-being in childhood and adulthood (Corbin et al., 2014). Therefore, such studies are very important aiming at improving children's health indicators. Methods Data from 242 primary school students aged 7 – 11 years were gathered, 52.7% of them were boys. The 9 items test battery, developed by Fjørtoft et al. (2011), included the following tests: standing broad jump, jumping a distance of 7 m on 2 feet, jumping a distance of 7 m on one foot, throwing a tennis ball with one hand, pushing a medicine ball with 2 hands, climbing wall bars, performing a 10 x 5 m shuttle run, running 20 m as fast as possible, and performing a reduced Cooper test (6 minutes). Results Boys performed better than girls ($p < .05$) on total fitness and most separate tests, except for performing a 10 x 5 m shuttle run, jumping a distance of 7 m on 2 and 1 feet. Comparison of physical abilities of differently aged boys has shown that strength and strength endurance indicators improve with age. Agility, coordination, aerobic endurance did not statistically significantly differ comparing the indicators for 7-, 8-, 9-, and 10- year-old boys. Comparing physical fitness indicators for differently aged girls we did not find statistically significant differences. Height, weight, BMI and body fat mass were not related to the total physical fitness. Pushing a medicine ball with 2 hands was associated with a higher score on height, weight and BMI ($r = .332, .343, .260$, respectively). Discussion Results obtained from the girls do not reflect the distribution of the overall children's physical fitness indicators in the aspect of age groups. While the improvement of these indicators is observed with age, it is not statistically significant ($p > .05$). These findings may be influenced by the small sample size which is characteristic of the pilot study. We did not observe significant differences comparing physical fitness indicators for children in Lithuania and other countries. Boys' physical fitness indicators improved with age and were statistically significantly ($p < .05$) different from those of girls. References Corbin, C. B., Welk, G. EFFECTS OF RESISTANCE TRAINING WITH ELASTIC BANDS AT DIFFERENT LEVELS OF INTENSITY ON THE IMMUNE SYSTEM OF OLDER ADULTS

MUNOZ CUTILLAS, V.1, GARGALLO, P.1, JUESAS, A.1, SAEZ, G.1,2, ESTAN, N.2, COLADO, J.C.1

University of Valencia

1: University of Valencia (Valencia, Spain), 2: Clinical Analysis Service, University Hospital Dr. Peset, (Valencia, Spain). Introduction Resistance training has proven to be an efficient method for the improvement of the immune system (IS) in older adults (OA) but there are no evidences that the use of elastic bands is efficient for these purposes. The main objective of this study was to analyse the chronic effects of a strength training program with elastic bands at different intensities, on the IS parameters and the inflammatory profile of OA. Methods 86 OA (69.47 ± 5.16), were randomized in 3 groups: Control group (CG) ($n=37$), Moderate Intensity Training Group (MITG) ($n=26$) and High Intensity Training Group (HITG) ($n=23$). 16 weeks (WK) of elastic bands (TheraBand) resistance training program was conducted, twice a WK, with 6 exercises. The training groups exercised at moderate and high intensity, performing 15 and 6 repetitions respectively, with a perceived exertion of 6-7 OMNI-RES for the first 4 WK and 8-9 the next 12 WK. Leukocytes (LK), neutrophils (NT), lymphocytes (LP), monocytes (MN), eosinophils (EN), basophils (BS), C-reactive protein (CRP) and interleukin 6 (IL) were measured. Non parametric tests were performed. Results Main results showed significant differences between HITG and MITG in LP and MN ($p < 0.05$) and a tendency in LK post measurement ($p < 0.09$) was detected. Differences in between the HITG and CG were found in LK and MN ($p < 0.05$). Significant differences occurred in the intragroup results of HITG in the LK (-7.27%) and monocyte variable (-20%). In the intragroup analysis, in MITG and HITG CRP diminished (-22.1% and -18.58% respectively), whereas CG increased IL-6 (+15.78%). Discussion Training protocol performed improved the immune response of both groups, even though high intensity is linked to a worsening of it. So, although it is claimed that there are no chronic changes in the IS in studies of less than 6 months of duration (Walsh et al., 2011), it has been proven that, after 4 months, signs of improvement of this system can be detected. THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, INACTIVITY AND PHYSICAL FITNESS AMONG LITHUANIAN PRIMARY SCHOOL CHILDREN

EMELJANOVAS, A., MIEZIENE, B., CESNAITIENE, V., PETERYTE, I., DAUGININKAS, D.

Lithuanian sports university

Introduction Recently it is emphasized that physical education should focus on physical fitness rather than physical activity (Corbin et al., 2014). Health related physical fitness acts as a preventive factor to various chronic diseases. The aim of this study is to examine the relationship of physical fitness and physical activity as well as inactivity in Lithuanian primary school students. Methods Data from 242 primary school students from grade 1 to grade 4 were gathered, 52.7% were boys. The 9-item test battery was applied to measure physical fitness. The test battery was developed by Fjørtoft et al. (2011) and included tests: standing broad jump, jumping a distance of 7 m on 2 feet, jumping a distance of 7 m on one foot, throwing a tennis ball with one hand, pushing a medicine ball with 2 hands, climbing wall bars, performing a 10 x 5 m shuttle run, running 20 m as fast as possible, and performing a reduced Cooper test (6 minutes). Data about leisure time physical activity and sitting time were also gathered. Results Regression analysis revealed that physical activity was related to total physical fitness ($\beta = .228, t = -2.590, p = .011$) and added 5% to total physical fitness variance until the inactivity was added to the equation. Then it became insignificant ($p > .05$). The results were obtained controlling for gender and age. Meanwhile, physical inactivity predicted lower total physical fitness ($\beta = -.278, t = -3.057, p = .003$) and added 6% to the explanation of physical fitness variance. Physical activity had positive predictive value on reduced Cooper test ($\beta = .200, t = -1.955, p = .05$). Physical inactivity predicted lower scores on throwing a tennis ball, running 20 m, performing a 10 x 5 m shuttle run ($\beta = -.225, t = -2.593, p = .01; \beta = .205, t = 2.003, p = .048; \beta = -.275, t = -2.623, p = .010$, respectively). Discussion Results of this study support the premise that poor physical fitness related to low physical activity,

extra sitting hours in leisure time and vice versa. Physical activity predicts higher endurance, which is closely related to cardiovascular health. Although the strength of physical activity and inactivity relationships varies for different components of fitness among primary school students, it is important to teach about these relationships in fitness education programs, and to measure all health-related fitness components (Corbin et al., 2014). CHANGE IN THE RELATIONSHIP AMONG SALIVARY BIOMARKERS OF CHILDREN AND ADOLESCENTS IN THE EARTH-QUAKE AND TSUNAMI DISASTER AREA.

SAKAMOTO, Y.1, OKAZAKI, K.1, SASAKI, K.1, UEKI, S.2, SUZUKI, K.3

1, Tohoku Gakuin University, 2, Osaka University of Health and Sport Sciences, 3, Juntendo University (Japan)

Introduction We have periodically investigated about the psychosomatic health of the elementary and junior high school students in the disaster area from September 2011 after half year of the Great East Japan Earthquake and tsunami. As a result, our study group reported that the subjects who survive the earthquake and tsunami experience a decrease in physical activity levels (Okazaki 2015). In addition, a significant fluctuation was observed by both of stress and immune index in the subjects (Sakamoto 2014), but the details are still unclear about these relations. The purpose of this study was to examine the relation between salivary stress and immune biomarkers in children and adolescents living in a town affected by the Great East Japan Earthquake and tsunami 2011. Methods Participants were 403 elementary and junior high school students (as of the first investigation in September, 2011) aged 9-14 lived in the town of Onagawa (the place where housing damage affected 60% of participants). The survey was performed 4 times in September 2011 (the disaster after six months; 6m), March 2012 (after 1 year; 1y), March 2013 (after 2 years; 2y) and March 2014 (after 3 years; 3y). Whole stimulated whole saliva samples were collected using Sal-i-kids Salivette tube, and saliva flow (SF; ml/min), secretory IgA (SIgA) concentration (SIgA-C; µg/ml), SIgA secretion rate (SIgA-SR; µg/min), and cortisol concentration (COR; µg/dL) were determined. Results COR was significantly decreased after 1y, 2y and 3y comparison with disaster after 6m, but SIgA-C was significantly increased after 1y, 2y and 3y. In addition, a significantly change was observed about SF and SIgA-SR through the survey period. Interestingly, COR was significantly increased after 3y comparison with disaster after 2y. So, when COR of 6m and 3y were respectively divided into two groups based on the median and compared each groups of salivary immune marker, there were significant difference observed with SIgA-SR of 6m, but there was not significant difference in each immune markers of 3y. Conclusion A long-term fluctuation was observed by the stress and immune marker of children and adolescents in the disaster area. In addition, these results suggest the possibility that different association was found between stress and immune markers with 6m and 3y. This study was supported by the Japan Society for the Promotion of Science (24680065 and 26750323). References Okazaki K, et al. VALIDATION OF PHYSICAL FITNESS TEST BATTERY IN LITHUANIAN PRIMARY SCHOOL CHILDREN: PILOT STUDY

MIEZIENE, B., EMELJANOVAS, A., CESNAITIENE, V., PAGIRSKAS, J., LIUDZIUS, D., FJØRTOFT, I.2, KJØNNIKSEN, L.2

1. Lithuanian Sports University 2. University College of Southeast Norway

Introduction Physical fitness (PF) is one of the main factors for health status. Studies show that poor PF in childhood and adolescence is a risk factor for future cardiovascular health. PF in high school children decrease over decades. There is a lack of instruments to measure PF in primary school. Methods Data from 129 first grade students were gathered. The 9-item test battery, developed by Fjørtoft et al. (2011), included tests: standing broad jump, jumping a distance of 7 m on 2 feet, jumping a distance of 7 m on one foot, throwing a tennis ball with one hand, pushing a medicine ball with 2 hands, climbing wall bars, performing a 10 x 5 m shuttle run, running 20 m as fast as possible, and performing a reduced Cooper test (6 minutes). Data about organized physical activity (PA), leisure sitting time and motor abilities (Herrmann et al., 2015) were also gathered. Results EFA confirmed one factor model. Means on each PF test were close to those of the Norwegian sample (Fjørtoft et al., 2011). Internal consistency of PF scale was good – Cronbach alpha .80. Test-retest reliability varied in the range from .561 to .768. Tests correlated with each other in the range from .174 to .575. Tests correlated with the total PF in the range from .579 to .795. Boys performed better than girls ($p<.05$) on total PF and most separate tests, except on jumping a distance of 7 m on 1 and 2 feet. PA had no relationship with total PF or separate tests in neither boys nor girls. Leisure sitting time was negatively related to 10 x 5 m shuttle run, running 20 m and total PF performance. PF was significantly associated with various motor abilities (e.g. bouncing, catching, dribbling) in the range from .242 to .514. Discussion PF tests battery for primary school children was developed as it should consist of compound activities that recruit various combinations of underlying components, such as strength, endurance, motor coordination, balance, and agility. Results show that the individual tests correlated reasonably well with each other. All of the individual tests' scores contributed to the total test score, without either very high or very low correlations. These results support the internal consistency of test battery. Test-retest reliability can be considered satisfactory. Construct validity is partly supported as girls performed worse than boys and those who are more inactive worse than less inactive. The relationship with motor abilities provided support for PF tests battery concurrent validity. References Fjørtoft, I., Pedersen, A. V., Sigmundsson, H., & Vereijken, B. LEAN BODY MASS INCREASE COULD SLOW DECREASE IN RESTING METABOLIC RATE AFTER WEIGHT LOSS

CASTRO, E., PEINADO, A.B., ESTEVES, N.K., BENITO, P.J., BUTRAGUEÑO, J., CUPEIRO, R.

Technical University of Madrid

Introduction A weight loss around 10% could be considered clinically meaningful (Sherwood et al, 2016). Some studies indicated a decrease in resting metabolic rate (RMR) after a weight loss program (WLP) (Knuth et al, 2014; Schwartz et al, 2012). However, studies examining the RMR response between responders and non-responders, classified those individuals by body weight loss and not by body composition (BC) changes (Herrmann et al, 2015; Tremblay et al, 2015), ignoring the effect that muscle mass can have over RMR (Müller et al, 2002). Therefore, the aim of this study was to investigate the RMR response between responders and non-responders regarding BC changes after a WLP. Methods One hundred and sixty-nine (82 males) overweight (W) and obese (O) participants (body mass index 25-34.9 kg/m²), aged 18-50 years, underwent a WLP during 24 weeks. Subjects were randomized into three training groups (strength train-

ing, endurance training or a combination of strength and endurance; training frequency 3 times/week) or a physical activity recommendations group. All in combination with a 25-30 % caloric restriction diet. RMR was measured by indirect calorimetry and the mean of the last 10 min in a lying position was used for analysis. BC changes were measured with DXA. Participants were classified as responders when they decrease their initial body weight by $\geq 10\%$ and increase lean body mass by $\geq 10\%$, and non-responders if these conditions were not satisfied. A one-way ANOVA with repeated measures was conducted. Results RMR decreased after the intervention (1706.15 ± 36.38 vs 1600.39 ± 31.33 kcal; $p < 0.001$) within the whole group, without differences between individuals who lost more (-105.82 ± 44.19 kcal; $p = 0.018$) and less (-110.73 ± 31.11 kcal; $p < 0.001$) than 10% of their initial body weight. However, responders did not change their RMR (-98.98 ± 50.42 kcal; $p = 0.051$) while non-responders significantly decreased it (-112.56 ± 29.45 kcal; $p < 0.001$). Discussion The causes for the metabolic adaptation to weight loss are still unclear and some studies indicated that only FFM maintenance prevents the slowing of metabolic rate during active weight loss (Johansen et al., 2012; Knuth et al., 2014). A lean body mass increase could be necessary to maintain RMR and our results reinforce this hypothesis. References Herrmann SD, et al (2015). *Obesity* (Silver Spring), 23(8):1539-49. ADOLESCENTS ATHLETES AND NON-ATHLETES: DO THEY DIFFER IN HEIGHT, WEIGHT AND BMI?

MARKOVIC, L., GUSIC, M., MAKSIMOVIC, D., MARINKOVIC, D.

Faculty of Sport and Physical Education

Introduction Adolescence is considered as a risk factor for inactivity (Rowland, 1999). Owing to the high risk of overweight adolescents becoming obese adults, the engagement of adolescents in sports is a fundamental goal of obesity prevention (Hills et al., 2015). The aim of this study was to analyze differences in early adolescents, athletes, and non-athletes, in terms of anthropometric parameters: body height, body weight, and BMI. Methods The study was conducted on the sample of 214 male 5th-grade students of elementary schools in Novi Sad (Serbia), between 11-13-years of age, divided into 4 groups: 61 non-athletes, 72 soccer players, 46 basketball players, and 35 martial arts athletes (judo, karate, kickboxing, taekwondo, and aikido). The adolescent athletes were involved in sports not less than 2 years. The groups were compared in 3 different anthropometrical variables: height, weight, and BMI. Differences between groups were analyzed by one-way ANOVA (Post Hoc), Kruskal-Wallis, Mann-Whitney, and Chi-square test. Results Students who were engaged in basketball, on average, were the tallest, the heaviest and had the highest BMI. Students who played soccer were, on average, the shortest, of the lowest weight and had the lowest BMI. The greatest similarity exists between martial arts athletes and non-athletes. A statistically significant difference in average height was identified only between soccer and the basketball players ($p=0.024$). As regards weight and BMI, there were significant differences among all groups, except between martial arts and non-athletes groups. Percentage of overweight early adolescents (obesity included) ranged from 8.3% in football players to 41.3% in basketball players. In martial art athletes and non-athletes, this percentage reached 22.9% and 24.6%, respectively. Discussion Early adolescence is a delicate developmental phase and individual differences in maturation might affect the results (Beunen et al., 1988). A permanent engagement in selected sports can affect the nutritional status as well as other biological parameters in youth. Sports selection (natural and intentional), might also be a factor of influence: tall children are selected to basketball, soccer require fast and agile players. Some sample issues (mixed martial arts group, a number of participants) might also affect the results obtained. TENNIS PLAYING LIMITS UPPER EXTREMITY SUBCUTANEOUS FAT ACCUMULATION IN PREADOLESCENTS: A VOLUMETRIC STUDY USING MRI

DORADO, C., HERNÁNDEZ-VELÁZQUEZ, J.A., CALBET, J.A.L., SANCHIS-MOYSIS, J.

University of Las Palmas of Gran Canaria

Research Institute of Biomedical and Health Sciences (IUIBS), Las Palmas de Gran Canaria, Canary Islands, Spain. Introduction. Tennis submits the arm that holds the racket (dominant arm) to a great amount of exercise compared to the contralateral. Nowadays, little is known about the effects of tennis on the fat mass in preadolescents (1). Subcutaneous adipose tissue (SAT) is a component of the fat mass with a great interest for health (2) that can be measured with great reproducibility in children using magnetic resonance imaging (MRI) (3). The main aim of the present study was to determine if playing tennis at pre-pubertal ages is associated with lower upper extremity SAT accumulation compared to non-active boys. Methods. MRI was used to determine SAT in 17 male preadolescents (11.0 ± 0.8 years, Tanner 1-2), not obese and healthy. Seven were tennis players (playing frequency 5 d/w, at least 2 y; TP) and 10 were physically non-active controls (CG). Contiguous MRI images were used to calculate the volume of SAT of each arm independently (from the axilla to the head of the radius) (4). Differences between groups were established using ANCOVA, with height as covariate, and Bonferroni-Holm post hoc test (5). Side-to-side differences were assessed using Student's paired t-tests. Significant differences were assumed when $P < 0.05$. Results TP and CG had similar age, height, weight and pubertal status ($P = \text{NS}$). Body mass index was lower in TP than in CG (17.2 ± 1.4 vs. 19.6 ± 2.3 , respectively, $P < 0.05$). The TP had lower SAT than the CG in the dominant and non-dominant upper extremity ($P < 0.05$), also after adjusting for height as covariate (dominant: 379.25 ± 54.26 vs. 596.98 ± 47.82 cm 3 , $P < 0.05$; non-dominant: 381.01 ± 49.29 vs. 586.43 ± 43.44 cm 3 , $P < 0.01$). The dominant and non-dominant arm had a similar volume of SAT in the TP (386.50 ± 104.53 vs 387.32 ± 97.67 cm 3 , respectively, $P = 0.89$) and in the CG (591.34 ± 182.49 vs 581.52 ± 162.91 cm 3 , respectively, $P = 0.27$). Discussion This study shows that tennis playing 5 days per week is associated with lower SAT accumulation in the upper extremities of male preadolescents compared to sedentary controls. Interestingly, this difference (35%) is lower than the observed in the trunk of the same children (54%, unpublished data). Another finding is that in the TP and in the CG the volume of SAT is similar in both arms. References 1. Sanchis-Moysi J, et al. *J Sports Med Phys Fitness*. 2011;51(3):409-16. 2. TRUNK SUBCUTANEOUS FAT IN PREPUBESCENT TENNIS PLAYERS AND SEDENTARY CONTROLS: A VOLUMETRIC STUDY USING MRI

SANCHIS-MOYSI, J., SANTANA-GONZALEZ, C., CALBET, J.A.L., DORADO, C.

Research Institute of Biomedical and Health Sciences (IUIBS), Las Palmas de Gran Canaria University

Introduction. Childhood obesity is an important public health issue worldwide (1). Tennis may help to reduce fat mass accumulation in children (2). Subcutaneous adipose tissue (SAT) is a component of the fat mass that has a great interest for health (3). Magnetic resonance imaging (MRI) is the gold standard method to determine SAT in children (4). The main aim of this study was to determine if playing tennis at pre-pubertal ages is associated with lower trunk SAT compared to non-active boys. Methods. MRI was used to determine SAT in 17 male preadolescents (11.0 ± 0.8 years, Tanner 1-2), not obese and healthy. Seven were tennis players (playing frequency 5 d/w, at least 2 y; TP) and 10 were physically non-active controls (CG). Contiguous MRI images from T3-T4 intervertebral disc to pubic symphysis were used to calculate the volume of trunk SAT (5). Differences between groups were established using ANCOVA, with height as covariate, and Bonferroni-Holm post hoc test. SAT differences between abdominal (L1-L2 intervertebral disc to pubic symphysis) and thoracic sub-regions (T3-T4 to L1-L2 intervertebral discs) were assessed using Student's paired t-tests. Significant differences were assumed when $P < 0.05$. Results TP and CG had similar age, height, weight and pubertal status ($P = NS$). Body mass index was lower in TP than in CG (17.2 ± 1.4 vs. 19.6 ± 2.3 , respectively, $P < 0.05$). TP had lower total trunk, thoracic and abdominal SAT than CG ($P < 0.05$), also after adjusting for height as covariate (Total: 2046.2 ± 607.4 vs. 4088.0 ± 508.0 cm³, $P < 0.05$; Abdominal: 1759.41 ± 508.30 vs. 3419.11 ± 425.10 cm³, $P < 0.05$; Thoracic: 286.8 ± 109.7 vs. 668.9 ± 91.7 cm³, $P < 0.05$). In both groups the abdominal sub-region accumulated more SAT than the thoracic ($P < 0.05$) displaying a similar distribution (86 vs. 14% in TP and 84 vs. 16% in CG, respectively; $P = NS$). Discussion Tennis playing 5 days per week is associated with lower trunk SAT accumulation in male preadolescents compared to sedentary controls, due to lower abdominal (49%) and thoracic SAT (58%). The distribution of SAT between the abdominal and the thoracic sub-region is similar in TP and control children (84-86% greater SAT in the abdominal region). This information could help to promote policies aiming at reducing the prevalence of obesity in children and prevent the associated risks for health. References 1. Keke LM, et al. DIFFERENCES IN ANTHROPOMETRIC CHARACTERISTICS BETWEEN CHILDREN SOCCER PLAYERS: TODAY AND EIGHT-EEN YEARS AGO

GUSIC, M., MOLNAR, S., SMAJIC, M., MARKOVIC, L., MAKSIMOVIC, D., MARINKOVIC, D.

Faculty of Sport and Physical Education

Introduction The aim of this study was to determine significant differences in some anthropometric characteristics between children soccer players aged 7-10. Over the last two decades, percentage of overweight and obese children is rapidly growing (Podstawska and Borysławski, 2012), which made many researchers, doctors and sociologists to feel the need of exploring the various possibilities of preventing this negative tendency, by collecting and analyzing a specific bit of information that aids in understanding growth and maturation. Methods This study was conducted on the entity of 150 male subjects aged 7-10 divided into two groups: 90 soccer players measured at present and 60 soccer players measured 18 years ago. A t-test was used for comparison of 9 anthropometric variables: height, weight, BMI, knee diameter, circumference and skin folds of upper and lower leg. Results Based on compared data, significant differences ($p < .01$) were found in 8 variables where the group that was measured at 1997 had significantly lower values than group measured at 2015. The only variable that had no significant differences was: lower leg skin fold. Discussion It appears that, at present, children spend less time practicing sports or physical activities, while they devote more time to activities such as watching television and playing video games (Vicente-Rodriguez et al., 2003). Sedentary lifestyle and badly programmed diet combined with physical exercise will result in changes of bodily composition (Prskalo et al., 2015.), which will mostly reflect on the quality of life of an individual. The importance of similar research topics (secular, longitudinal studies) has great interests for the global community, all in a cause of understanding variations of population's growth and maturation through time. It is yet to find out if synergy of factors such as nutrition, a specific type of physical activity or sociology-cultural factors has a predictive influence on referent dynamics of growth and maturation. Secular trend in height has stopped in many developed countries while weight has continued to increase (Malina, 2014) resulting in increase in overweight and obese. References Malina RM. (2004). EFFECT OF EXPIRATORY MUSCLE STRENGTH TRAINING INTERVENTION ON THE MAXIMUM EXPIRATORY PRESSURE OF PARKINSON DISEASE PATIENTS

KUO, Y.C.1, CHAN, J.1, CHENG, C.F.2, LIAO, Y.H.1

1:National Taipei University of Nursing and Health Sciences (Taipei, Taiwan) 2:National Taiwan Normal University (Taipei, Taiwan)

Introduction A study asserted that the maximum peak expiratory flow of patients with Parkinson disease(PD) decreased with their decreasing maximum maximum expiratory pressure(PEmax)[1]. A recent study asserted that administering expiratory muscle training (EMST) to patients with PD noticeably improves their swallowing and coughing functions and PEmax [2]. The literature [3] administered a 20-week 75% PEmax intervention to 54 year-old patients with idiopathic PD (Hoehn & Yahr stage 2.5)[4] and confirmed that after 4 weeks and 20 weeks of intervention, the PEmax scores of the patients were improved by 50% and 158%, respectively. Through interventions of various training frequencies, this study investigated the effect of EMST on the expiratory muscular strength of these patients. Methods The participants were categorized into Experimental Group A/5DE(5 days/Week, training strength= 75%PEmax, n=4), Experimental Group B/3DE(3 days/week, training strength= 75% PEmax, n=5), and the control group/3DC(3 days/week, training strength= 0% PEmax, n=4). The EMST intervention mainly involved using an expiratory muscle strength trainer. The PEmax measurement method was conducted according to the ATS/ERS (2002). Results The PEmax of the 5DE group was significantly higher than that of the 3DC group ($\eta^2 = 0.64$; $P < .05$). Moreover, the posttest PEmax values of the 5DE group and 3DE group were significantly higher than their pretest values (5DE: 168 ± 73.48 cmH₂O vs 89.25 ± 46.67 cmH₂O, $\eta^2 = 0.91$; 3DE: 121 ± 56.16 cmH₂O vs 75.25 ± 29.09 cmH₂O, $\eta^2 = 0.73$; $P < .05$). However, the pretest and posttest PEmax values of the 3DC group differed nonsignificantly ($P > .05$). Discussion The PEmax values of Group A were significantly higher than those of the control group. Moreover, the PEmax values of Group A and Group B significantly increased by 88% and 61%, respectively, indicating that engaging in EMST 5 d/week or 3 d/week facilitates increasing the PEmax value. This result accords

with those of study [5], their results confirmed that the PEmax values of the two groups improved significantly. Several study that administering EMST 5 d/week to healthy but sedentary elderly adults, and patients with spinal injury facilitated improving their expiratory muscular strengths[6]. The study participants with an average Hoehn and Yahr stage of 2.89 and age of 72.78 years[7], which are higher than those of our study. The training strength was set to 5 days per week or 3 days per week, and the training period spanned 4 weeks. The results revealed that the expiratory muscular strength of the patients was significantly improved. References 1.Herer B., et al. (2001) Chest, 119(2), 387-393. 2.Silverman EP., et al. ARTIFICIAL CO2-WATER BATHING IMPROVED MUSCLE FLEXIBILITY AND HARDNESS IN MALE COLLEGE STUDENTS

YAMAMOTO, N.1, HASHIMOTO, M.2, WADA, T.3, TAKENOYA, F.4

1Japanese Red Cross Hokkaido College of Nursing, 2Teikyo. Univ. Sci., 3Kokushikan Univ., 4Hoshi Univ.

Introduction Facilitation of the blood supply to the muscle and of oxygen consumption in the muscle by a local immersion of the extremities into high concentration carbon dioxide water (CO₂-water, CO₂>1000ppm) (Yamamoto, 2007), suggests an improvement of muscle performance and joints flexibility. In the present study, we investigated the effect of artificially made CO₂-water immersion on both the flexibility and hardness of the muscles in healthy volunteers. Methods Five male healthy students (18-19 yrs, 169.7±2.6cm, 64.5±8.0kg, 15.7±2.9%fat) participated in this study. The subject equipped with probes and electrodes for measurements of the following parameters were immersed up to the xiphoid into CO₂-water (35 °C, 15 min) or control tap-water (CO₂<20 ppm), or seated in same position in bath-tub without water (Air). Blood flow in the immersed skin (BF), external ear cavity temperature (ETemp) and electrocardiogram (ECG) were recorded continuously throughout the experiment. Cardiac autonomic nerve activity was evaluated by power spectrum analysis (PSA) of R-R interval fluctuation in ECG. Muscles hardness (MH, left gastrocnemius dominant), range of motion at left ankle joint (Ankle ROM), sitting trunk flexion (flexibility) were measured before and after three different treatments. Results At 15 min of immersion, CO₂-water decreased heart rate (HR) whereas the other 2 treatments did not. BF was significantly larger in CO₂-water immersion throughout the recording period compared to the other 2 treatments. Ankle ROM was significantly increased by water immersion irrespective of CO₂-concentration, whereas Air was not. Improvement of flexibility and decrement of MH were observed only by CO₂-water treatment. A power ratio, LF(0.04-0.15Hz)/HF(0.2-0.4Hz), in PSA was smaller in CO₂-water treatment than in tap-water treatment, while HF-power did not change. Discussion Our present result supports the previous study showing that LF/HF ratio, an indicator of cardiac sympathetic nerve activity, was smaller in CO₂-water immersion than in tap-water immersion (Sato, 2009). HR decrease in CO₂-water immersion also suggests a suppression of sympathetic nervous system. We reported previously that the muscle blood flow in the immersed part was larger in CO₂-water than tap-water of a same temperature. Muscular sympathetic activity might not be inhibited. Though the underlying mechanism is still unknown, considering effects of CO₂-water bath on those parameters, i.e. MH and trunk and ankle flexibilities, this water treatment may be useful to preconditioning of muscle and also to recovery from fatigue. THE INFLUENCE OF GROUP STAY ACTIVITY ON MORNING BODY TEMPERATURE AND ABILITY TO GET UP AFTER SLEEP IN ELEMENTARY SCHOOL 5TH GRADERS

HISAKAWA, H., TANAKA, R., SHIKANO, A., NOI, S.

Nippon Sport Science University

Introduction Disorder in children's living habits such as 'the child who stays up late' and 'the child who cannot get up in the morning' are concerns in Japan. Under such circumstances, Japanese elementary schools, aiming to rebuild children's lifestyle, have carried out collective accommodation activities such as natural classrooms and open-air schools. Musashino-shi, Tokyo, has been providing population accommodation activities for about one week with a faculty discount rate. While the children are feeling the benefits of these activities, verification of their effects is an issue there. Therefore, the group stay activity in this city does affect the morning body temperature of the child according to this research. Methods The target was 532 fifth-year students enrolled in public elementary schools in Musashino-shi, Tokyo. The survey, a self-completed health questionnaire, covered accommodation activity over the previous five days, body temperature at waking up following accommodation activities for seven days, bed time, and a record of factors such as wake time. In the five days before the accommodation activities, children less than 36 degrees C was more than three days were classified as 'hypothermia trend group', children less than 36 degrees C was less than two days were classified as 'standard body temperature group'. And the mean of morning body temperature, bed time and wake-time during all 12 days were calculated. Results Morning body temperature, bed time, wake-time 'body temperature group factor,' and changes in the period of time 'period factor' were confirmed through two-way analysis of variance. Significant interactions were observed in all factors. Further, changes in morning body temperature during periods, compared to the standard group body group, the hypothermia tends group, how will significantly elevated from further Specialty activities Day 3 was confirmed. In addition, the bedtime of the prior hypothermia trend group, wake-time was found to be a late sleep late happened trend as compared to the standard body temperature group. Discussion According to Noi et al. (2003), the waking axillary temperature of a hypothermia trend group is less than 36 degrees C compared to 36 degrees C in the standard body temperature group; it has been reported to peak at a later time. And, Shibata et al. (2011) found the average time of waking up at night with a minimum skin temperature in the low body temperature group to be significantly delayed in the morning compared to the control group. Therefore, it is possible to guess the phase of the preliminary body temperature rhythm to which I was retreating when getting up by the hypothermia tendency group in this research, after the phase of the preliminary body temperature rhythm to which I was retreating moved to a background of a change's in the body temperature being remarkable with stay activity. QUALITY OF LIFE IN THE SUBJECTIVE EVALUATION OF THE ELDERLY IN POLAND

SŁAWIŃSKA, T., IGNASIĄK, Z., SKRZEK, A., KOCHAN-JACHEĆ, K., POSŁUSZNY, P.

University School of Physical Education in Wrocław

Introduction: Quality of life is a multidimensional concept. Its self-assessment depends on the degree of fulfillment of life goals, health condition, leisure activities, the efficiency of performing daily routines, family and social relationships. All of these factors are influenced by independent variables such as age and gender. The aim of the study was to determine which of the areas of quality of life (somatic,

psychological, social, environmental) has the greatest impact on quality of life self-assessment made by men and women after 50 years of age. Material and methods: The quality of life survey was conducted among 1314 elderly people (≥ 50 years) living in the cities and towns of the region of Lower Silesia (Poland) in 2010-2015. The groups of women (n = 988) and men (n = 326) were divided into age subgroups: younger (50-65 yrs) and older (65-80 yrs). Quality of life was tested by the short version of WHOQOL. Results: Women estimated their quality of life higher than men. Taking age into consideration, the self-assessment was higher among women of the younger subgroup, while among men the members of the older subgroup rated their quality of life higher. According to the surveyed persons, the factors with significant effect on the quality of life were personal relationships (social domain F=8,324, p=0,003978), the availability of information in day-to-day life and the acceptance of own physical appearance.

MARCHING IN THE RIGHT DIRECTION: REPORTING ON THE BENEFITS OF A HOLISTIC HEALTHY LIFESTYLE INTERVENTION FOR EMIRATI NATIONAL SERVICE RECRUITS.

AL SHEHHI, M.1, PICKNELL, G.1, NICHOLSON, G.1, ALLEN, D.1, LAWTON, K.1, GILL, J.2, ROSS, R.3

1:United Arab Emirates Armed Forces (UAE), 2:University of Glasgow (UK), 3:3Dimensions Physical Performance LLC (UAE)

Introduction Recent evidence suggests that the rapid rate of urbanisation within the United Arab Emirates (UAE) in recent years has contributed to a less physically active Emirati society, compared to previous generations, and nutrition transitions that are in stark contrast to Bedouin traditions (Ng et al., 2011). This has resulted in increased health related diseases associated with higher overweight and obesity prevalence. Recognising the potential economic cost of supporting a nation that is getting unhealthier and evermore exposed to preventable communicable and non-communicable diseases, the UAE Government has invested heavily into preventative health services that are readily available for UAE Nationals. This study reports initial results of healthy lifestyle interventions carried out as part of the UAE's National Service military training. Methods National Service Recruits (age: 20.63 ± 4.57 yrs, body mass index (BMI): $28.71 \pm 8.47 \text{ kg} \cdot \text{m}^{-2}$, n=2846), attending a residential military training camp, participated in a range of health interventions over the course of a 12 week basic training period. These included a calorie controlled menu, individual and group dietetic and weight management clinics, a health education curriculum and ability-specific physical training programmes. Quantitative data were collected at the start (T1) and end (T2) of Phase 1 of National Service Training. Results During the 12 week training period the percentage of recruits with a BMI $> 25.00 \text{ kg} \cdot \text{m}^{-2}$ (n=1764) decreased (T1 61.98 %, T2 50.98%), with weight loss (T1 100.14 ± 19.93 , T2 88.49 ± 16.91 kg; t=100.91, P<.001) and waist circumference reductions (T1 105.61 ± 14.95 , T2 92.97 ± 13.52 cm; t=71.25, P<.001). Health knowledge improved ($53.05\% \pm 1.06$; t=56.48, P<.001). Overall, physical fitness improved: one mile run time decreased (T1 $11:53 \pm 03:13$, T2 $10:45 \pm 02:27$ min:ss; P<.001); push-ups increased (T1 17.34 ± 11.78 , T2 23.35 ± 12.37 reps•min; P<.001); sit ups increased (T1 24.47 ± 9.70 , T2 28.66 ± 9.55 reps•min; P<.001); and squats (T1 31.11 ± 13.25 , T2 37.71 ± 12.98 reps•min; t=26.55, P<.001). In addition, overall physical fitness of obese (BMI $> 30.00 \text{ kg} \cdot \text{m}^{-2}$; n=368) recruits improved: predicted VO₂ increased (T1 26.50 ± 9.40 , T2 $34.38 \pm 10.15 \text{ mL/kg} \cdot \text{min}$; P<.001); push-ups increased (T1 6.45 ± 6.43 , T2 9.22 ± 7.99 ; P<.001); sit ups increased (T1 16.29 ± 7.61 , T2 18.56 ± 7.76 ; P<.001); and squats increased (T1 21.75 ± 10.38 , T2 26.21 ± 11.47 ; P<.001). Conclusion Significant health knowledge improvements were reported over the intervention period, coinciding with favourable changes in fitness and body measures. A limitation was the relatively short duration of the healthy lifestyle intervention. For longer-lasting improvements, ongoing research is needed in order to follow-up the recruits' health and fitness status to determine whether lifestyle changes are being maintained. DESCRIPTIVE EPIDEMIOLOGY OF PHYSICAL ACTIVITY, BODY COMPOSITION AND QUALITY OF LIFE AMONG BRAZILIAN MILITARY POLICE OFFICERS

BARBOSA, W., FONTANA, K.E., MOLINA, G.E., KORRE, M., LOFRANO-PORTO, A., KALES, S.N., PORTO, L.G.G.

Fac of Physical Education-Univ of Brasilia, Brazil; Dep of Env Health-Harvard T. H. Chan School of Public Health, USA; Endocrine Unit-Univ Hospital and Molecular Pharm Lab, Univ Brasilia, Brazil

Introduction Policing has been recognized as a hazardous occupation associated with intense physical and psychological demands. Obesity and physical inactivity rates are rising among police officers, however little is known about their association with quality of life in this population. Objectives: We aim to evaluate the association between physical activity level (PAL) and body composition (BC) with the quality of life (QOL) among Brazilian military police officers. Methods We conducted a cross-sectional study among 418 volunteers (88.3% men), recruited from 12 out of 14 police departments of a northern state of Brazil. PAL was evaluated by the IPAQ-questionnaire, categorizing volunteers as active (AT: ≥ 150 min/w) or insufficiently active (IA: < 150 min/w), and by the total accumulated METs per week. BC was estimated by BMI and obesity was defined as $BMI \geq 30 \text{ kg/m}^2$. QOL was evaluated by the WHOQOL questionnaire in a scale of 0 (worst) to 100 (best) score, among 4 domains: physical (PHD), psychological (PSD), social relationships (SRD) and environment (EVD). Descriptive statistics were calculated and t-test was used for group comparison, at the 5% level of significance. Results Mean age and BMI were 38.6 ± 6.6 yrs and $26.5 \pm 3.4 \text{ kg/m}^2$. 44.3% of police officers were IA and 16.3% were obese. Obese officers had only about one half of the physical activity performed by the non-obese ones (867 ± 820 vs 1582 ± 1221 METs/w; p<0.001). Mean QOL was 67 ± 16 for PHD, 72 ± 13 for PSD, 74 ± 15 for SRD and 59 ± 14 for EVD. IA officers showed lower QOL for PHD (-8.6%), PSD (-5.4%) and EVD (-6.7%) (p<0.02), as compared to the active ones. QOL among men was lower for PHD (-9.5%) and EVD (-8.0%), as compared to women (p<0.001). There were no differences on QOF between obese and non-obese. Discussion Even though prevalence of obesity was similar to the general population in the same region and year (16.3% vs 16.8%), the proportion of IA officers was lower (44.3% vs 51.1%) (Brazil, 2013), as were the QOL of the IA subgroup and the male officers. Future research is needed to investigate determinants of QOL among male and IA officers and on specific strategies to promote physical activity in obese police officers. References Brazil. STAIR DESCENDING EXERCISE INDUCED PHYSIOLOGICAL BUT NOT BIOCHEMICAL ADAPTATIONS IN ELDERLY MALES WITH CHRONIC CORONARY ARTERY DISEASE

THEODOROU, A.A.1, PANAYIOTOU, G.1, PASCHALIS, V.2, NIKOLAIDIS, M.G.1

European University Cyprus

Introduction Mean life expectancy has increased dramatically during the twentieth century, and it is expected that it will continue to increase. What will be the quality of these additional years of life? Today, older individuals can gain a lot by keeping their muscle strength

and functional performance through physical activity. Thus, is more urgent than ever the development of new methods and training regimes. It is important for modern exercise types to be easier to be performed than traditional exercise modes and more importantly to exert favorable effects on human health and performance. Methods Participants were allocated into: a stair descending group ($n = 10$, age 67.5 ± 1.3 yr, mean \pm SEM) and a stair ascending group ($n = 10$, age 65.6 ± 2.2 yr). Participants performed an acute bout of stair descending or stair ascending exercise (about 1) on an automatic escalator (4 sets of 3 min each, speed was set at 45 steps·min⁻¹, in total 540 steps for both groups). Before and at day 2 post exercise, physiologic measurements were performed and blood samples were collected for the measurement of blood lipids. Then, participants carried out eight weeks of stair descending or ascending training consisting of three exercise sessions per week. Afterward, they repeated the acute stair descending or ascending protocol (bout 2), as carried out at the beginning of the study, and the same physiologic and biochemical measurements were performed. A three-factor ANOVA (group \times bout of exercise \times time) was used to analyse muscle function and blood lipids profile. Results On the basis of the evidence derived from the present study, stair descending exercise markedly increased muscle strength and performance after eight weeks of stair descending exercise. Moreover, it was found that the first bout of stair descending exercise caused muscle damage, insulin resistance and affected positively TG and TC concentration; however, after the second bout the alterations in all parameters were diminished. Discussion Although we failed to find any effect of 8 weeks of stair descending exercise on blood lipids, stairs descending exercise increased muscle strength. Maintaining muscle strength in the elderly is of great importance so that individuals can function more readily in daily life activities. Furthermore, the fairly light intensity and metabolic cost of stair descending exercise and the short duration of each exercise session, are potentially important practical advantages of this type of exercise. Particularly, in individuals with restricted physical ability such as elderly and CAD patients where high metabolic demand of exercise is not desired.

IMPROVEMENT OF ANIOXIDANT CAPACITY IN PRE-DIABETIC MEN AFTER ECCENTRIC HYPOXIC EXERCISE TRAINING

KLAROD, K., PHILIPPE, M., GATTERER, H., BURTSCHER, M.

University of Innsbruck

Introduction Oxidative stress might be linked to the development of diabetes mellitus (DM) (Rani et al., 2016). Eccentric exercise training was shown to decrease insulin resistance (Paschalidis et al., 2011) and enhance anti-oxidative capacity (Child et al., 1999). Additionally, hypoxia increases reactive oxygen species and might also lead to specific redox adaptations (Bailey et al., 2001a). Thus, we aimed to investigate the effects of 3 weeks of eccentric hypoxic exercise on oxidative stress and antioxidant levels in pre-diabetic men. Methods Six pre-diabetic men (age: 51-67 years) not habituated to eccentric exercise and without altitude exposure (> 1500 meters) for 2 months prior to the start of the study were included. Participants performed 3 weekly downhill walking sessions down from an altitude of 2500 m to 2000 m for 3 weeks. Blood samples were taken before the first exercise session, immediately after the first session, during the third training week and 24 hours after the last training session. From the blood samples the reactive oxidative metabolites (dROMs) and the biological antioxidant activity of plasma (BAP) were determined using the Free Carpe Diem device (FREE® Carpe Diem; Diacon International, Italy). Results dROMs after the first training session were significantly higher compared to pre-exercise (9.73%, $p = 0.027$). BAP levels were significantly increased after the first training session, during the third training week, and 24 hours after the last training session compared to pre-training (55.64%, 72.77%, and 81.76%). Discussion The demonstrated increases in the antioxidant capacity may have developed under conditions of higher oxidative stress (Savu et al., 2012). Since oxidative stress was elevated even after the first training session, the higher antioxidant capacity after 3 weeks of downhill in hypoxia might be considered as specific adaptation to repeated increases in oxidative stress levels (Dillard et al., 1978; Askew, 2002). Therefore, eccentric hypoxic exercise training might have preventive effects in patients suffering from pre-diabetes. References Askew EW. (2002). Toxicology, 180, 107-19. THE EFFECT OF SLEEP ON RECOVERY FROM CENTRAL FATIGUE

SHIODA, K.1, SUGIMURA, H.2

1: Kanagawa University, 2: Kohoku Family Clinic

Introduction For all athletes, sleep is crucial for recovery from peripheral and central fatigue. Although there have been many reports on the effect of sleep on recovery from fatigue, it is unclear that the precise relationships between sleep and recovery from central fatigue resulting muscle contraction. Furthermore, it remains uncertain whether the quality of nocturnal sleep promotes recovery from central fatigue. The interpolated twitch technique (ITT) is widely used to assess voluntary activation (VA) of skeletal muscles (Merton, 1954). In addition, the reduction of VA in maximal efforts is the sign of central fatigue (Gandevia, 2001). The purpose of this study, therefore, is to investigate the effect of nocturnal sleep on recovery from central fatigue, using ITT and polysomnogram (PSG). Methods Healthy young adults who did not have sleep problem were recruited. They participated in three experimental conditions in random order: sleep (0%), partial sleep deprivation (50%) and total sleep deprivation (100%) conditions. They performed isometric maximum voluntary contraction of elbow flexor muscles for assessing VA using ITT before and after each condition. PSG including electroencephalogram, electro-oculogram, electromyogram, and heart rate were recorded during the nocturnal sleep. In addition to ITT and PSG, subjective fatigue and sleep index were measured using visual analogue scale (VAS) and Stanford Sleepiness Scale (SSS). Results and Discussion There were certain differences in VA, VAS and SSS between conditions. Furthermore, the results show that there were positive relationship between sleep variables and fatigue index. In conclusion, the present study revealed that nocturnal sleep plays an important role in the recovery from central fatigue for assessing ITT. References Merton PA. (1954). A POSSIBILITY TO PROMOTE THE PHYSICAL RECOVERY BY SLEEP AFTER CO₂-WATER BATHING IN ATHLETES

WADA, T.1, YAMAMOTO, N.2, WADA, M.1, SHINTAKU, Y.3, IWAHARA, F.4, TAKENOYA, F.5

1: Kokushikan University, 2: Japanese Red Cross Hokkaido College of Nursing, 3: Biwako Seikei Sport College, 4: Japan Sport Council, 5: Hoshi University

Introduction The bathing and sleep processes in physical recovery play an important role in human. Sleep is homeostatically controlled and, after a prolonged period of stress, we recognize importance of the sleep. Exercise load and sleep deprivation (SD) results in an increase in sleep, indicating that sleep is tightly maintained at a restricted level (Borbely and Achermann, 1999). It has recently been reported that SD induces the expression of heat shock protein (HSP) family members (Terao et al., 2003). HSPs are an important family of endogenous protective proteins that are induced in response to a wide variety of stresses, such as heat shock, hypoxia, hydrogen peroxide, inflammation, ischemia (Jaattela, 1999) and exercise load. The purpose of this study is to examine the physical recovery by sleep after CO₂-water bathing in athletes. **Methods** Eight healthy college athletes participated in this study. The subjects were taken two different types of bathing; tap-water bathing and CO₂-water bathing. The water temperature of both bathing was 38 degrees Celsius. The subjects were attached to surface electrodes on their forehead to record an EEG. To measure the sleep-wake cycle, accelerometers (Lifecorder GS, SUZUKEN, Japan) was used. The sleep - wake data were analyzed by circadian rhythm analysis software (SleepSign Act, KISSEI COMTEC, Japan). SpO₂ and body movement and pulse were measured by means of near-infrared spectroscopy (PulseWatch PMP-200, Pacific Medico, Japan). Sleep variables analyzed time in bed (TIB), sleep period time (SPT), total sleep time (TST), wake time after sleep onset (WASO), sleep efficiency (SE), sleep latency (SL), time of sleep onset, time of wake onset, and bed out latency (BOL). Results and discussion SL was significantly shorter ($p<0.05$) in CO₂-water bathing than that in tap-water bathing. SE was significantly higher ($p<0.05$) in CO₂-water bathing than that in tap-water bathing. During sleep of the single night, the delta wave incidence of EEG appeared more in the sleep after CO₂-water bathing. Therefore, these results suggest that as CO₂-water bathing could raise body core temperature enough, this hyperthermia may cause a deep sleep. **Conclusions** Sleep is homeostatically controlled, and indeed, an increase in the NREM sleep is typically observed after CO₂-water bathing in comparison to tap-water bathing. The sleep after the CO₂-water bathing seems to be extremely useful in the physical recovery from fatigue. References Borbely AA, Achermann P. (1999). J Biol Rhythms, 14, 557-568. Terao A, et al. THE USE EMG AND MRI TO EVALUATE CORE STRENGTHENING PROGRAM

RUTKOWSKA-KUCHARSKA, A., SZPALA, A., DZIUBA, A.

University School of Physical Education, Wroclaw

THE USE EMG AND MRI TO EVALUATE CORE STRENGTHENING PROGRAM **Introduction** The curl – up exercise is advised both in prevention and treatment of the LBP. Compared to other core stability exercises, curl-up provides lower compressive loads for a given muscle challenge (Axler and McGill, 1997). The main aim, of the presented study, was the evaluation of the curl-up exercise based training on the electrical activity, surface, circumference and thickness of the spine stabilization muscles. The question that we aim to answer is this: does the curl-up based training, with own body mass load, improves local muscle strength or local muscle endurance? **Methods** The exercises were performed during 4 weeks. The experiment participant was training 3 times per week (Monday, Wednesday, Friday), under a personal trainer's supervision. In the first week, the training comprised of 10 repetitions, in the second 20, in the third 30 and finally, in the 4 week 40 repetitions during one series. Before and after each training session, an MVC measurement, of the following muscles, was taken: rectus abdominus (RA), external oblique (OE) and erector spinae (ES). In order to evaluate training effectiveness MRI was used too. The following geometric parameters were measured and calculated: cross sectional area – CSA, muscle thickness of the right and left sides of the following muscles: rectus abdominus (RA), anterolateral abdominal (ALABD), psoas major (PS), quadratus lumborum (QL), lumbar erector spinae (ES), multifidus (MF) **Results** A statistically significant increase in the amplitude of the EMG was found only for the upper part of the m.RA. The effects training program on the morphology of muscles was assessment using MRI method. Cross sectional area of all the muscles, except QL changed significantly. Training has also changed the surface RA (right side), ALABD and ES (left side). The thickness of the muscle OAE and OAI increased after training on both sides of the body and TA only on the left side. All MRI parameters had shown symmetry. The EMG activity asymmetry, of the ES muscle, persisted after 4 weeks of training; however it was not statistically important. On the other hand, the statistically unimportant asymmetry of the lower RA, after 4 weeks of training, became statistically significant. **Discussion** Our studies show that the own load curl up exercise increases muscle endurance not the local muscle strength. Enhancing lumbar stability by increasing local muscle endurance instead of local muscle strength is the safest and most justifiable approach. Therefore, this exercise is suitable for both the healthy patients and those suffering from LBP. Exercise curl-up can be performed either by people with LBP and healthy people because it can be modified so that it may be small, medium and large load on the muscles stabilizing the spine (Rutkowska-Kucharska and Szpala, 2015). CONFIRMATION REGARDING RELATIONAL CONSTRUCTION OF BODY COMPOSITION AND BMI IN PRESCHOOL CHILDREN.

SAKAI, T.

Chubu University

CONFIRMATION REGARDING RELATIONAL CONSTRUCTION OF BODY COMPOSITION AND BMI IN PRESCHOOL CHILDREN. Sakai, T.1, Fujii, K.2, Watanabe, T.3, Tanaka, H.4 1: College of Life and Health Sciences, Chubu University, Aichi, Japan 2: AIT (Graduate School of Business administration and Computer Science, Aichi Institute of Technology, Toyota, Japan) 3: Junior College Division, The University of Aizu, Fukushima, Japan 4: Faculty of Sociology, Ryutsu Keizai University, Ibaraki, Japan **Introduction** Obesity is a state wherein body fat accumulates to an abnormal degree, and detailed information about body composition is necessary to inspect the problems of obesity in children. In the present study, we measure body composition with machinery which can measure lean body mass in addition to a quantity of fat based on the multi-frequency BI (bioelectrical impedance analysis) method. This examines differences in body composition for preschool children, including differences according to sex, and correlates them within the measured values of BMI. **Methods** The subjects were 533 preschool children, comprising 260 boys and 273 girls. Body composition was measured using the body composition analyzer (MC-190EM, Tanita Corp., Japan). Statistical values for physique and body composition were calculated according to gender and age. In each age group of boys and girls, a regression analysis of %Fat for BMI was performed, after drawing regression polynomials from the first to the third order, a regression polynomial of a proper order was determined. With a similar method to that of measuring fat per-

centage, a regression polynomial of a proper order for muscle percentage was determined for each age group of boys and girls. Results There were no significant gender differences among each of the age groups in weight, however, significant differences were found in height within the 4-year-old age group (boys > girls). The fat percentages for girls were higher than boys, and the muscle percentages were the opposite. These results show that there were differences according to sex. We made our evaluations based on a regression analysis of fat percentages for BMI and muscle percentages. As a result, a high correlation was found between BMI and fat percentages in boys and girls. The relation of BMI and muscle percentages was the opposite of the relation of BMI to fat percentages, and we found a high negative relation between boys and girls. Discussion A significant regression tendency was confirmed from the present results of the regression analysis of fat and muscle percentages for BMI for preschool children. This suggests that BMI can also be used to evaluate the fatness or thinness of a preschool child. In short, BMI can be regarded as the index that can evaluate fat and muscle percentages from early childhood. REGULATION OF EXERCISE INTENSITY BASED UPON HEART RATE IN ENDURANCE SPORTS – EVALUATION OF TRAINING PRESCRIPTIONS BY THE AMERICAN COLLEGE OF SPORTS MEDICINE

OBERSCHELP, N., VOBEDA, C.

Ruhr-University Bochum, University Bielefeld

Physical inactivity and a sedentary lifestyle are becoming more and more important as risk factors for metabolic and civilization diseases. When it comes to prevent or counteract accompanying adverse effects, advice on the amount of time spent with physical activity and sport per week are highly dependent on the chosen training intensity. Numerous studies tried to deduce intensity recommendations for the use in cardiorespiratory endurance training in the general population. In this respect, the American College of Sports Medicine (ACSM) recommends the use of 60-80% heart rate reserve as optimal training intensity for healthy adult recreational athletes. Since these recommendations are based on findings derived from incremental test protocols, the purpose of this study was to evaluate the prescribed intensities in continuous endurance tests. Therefore, 7 non-endurance athletes without previous cardiovascular or pulmonary disease (2 male and 5 female; age: 49.4 ± 5.1 years; body mass: 71.0 ± 11.2 kg; height: 1.71 ± 0.08 m; BMI: 24.2 ± 2.4 kg/m 2 ; HRRest: 64.1 ± 5.2 bpm) participated in three continuous endurance tests on a cycle ergometer at 50%HRR, 60%HRR and 70%HRR for 35 minutes and an incremental test to determine the individual anaerobic threshold (iAnT) of each subject. During the continuous protocols heart rate was held constant after a 15minute warm-up throughout the whole test by regulating resistance. Peripheral blood lactate was collected from the earlobe to determine submaximal load. Starting load and extent of increase every 3 minutes in the incremental protocol were based on the anticipated iAnT. The individual HRR was calculated using a modified Karvonen-formula. The watt-values as well as the lactate-values detected in the continuous tests were compared to those elicited by the incremental protocol. Mean values in the continuous tests were 74.3 ± 33.6 watt (50%HRR), 90.5 ± 31.5 watt (60%HRR) and 97.9 ± 35.1 watt (70%HRR) for performance output, respectively. Mean lactate values were 1.39 ± 0.6 mmol/l, 1.96 ± 0.83 mmol/l and 2.53 ± 0.87 mmol/l, respectively. Mean values in the incremental tests were 1.49 ± 0.33 mmol/l for lactate at the individual aerobic threshold (iAeT), 2.99 ± 0.33 mmol/l for lactate at iAnT, 88.6 ± 29.8 watt at iAeT and 125.8 ± 32.6 watt at iAnT. The results support the recommendations of the ACSM, whereat exercising at 60%HRR seems to be a light endurance training at the iAeT whereas training at 70%HRR leads to a moderate strain. For high intensity endurance training, adult recreational athletes should consider loads that elicit a HRR far beyond 70%. Further studies are needed that fortify these findings in larger cohorts.

PHYSICAL ACTIVITY DID NOT ALTER WEIGHT LOSS AND BODY COMPOSITION OF WOMEN AFTER 6 MONTHS OF BARIATRIC SURGERY

SIMOES, R.A.1, PESSOTTI, E.R.1, RAVELLI, M.N.2, CRISP, A.H.2, RASERA JR, I.I, OLIVEIRA, M.R.M.3

1: Bariatric Clinic of Piracicaba, 2: FCFAR-UNESP, 3: IBB- UNESP

PHYSICAL ACTIVITY DID NOT ALTER WEIGHT LOSS AND BODY COMPOSITION OF WOMEN AFTER 6 MONTHS OF BARIATRIC SURGERY Simoes, RA.1, Pessotti, ER.1, Ravelli, MN.2, Crisp, AH.2, Rasera-Jr, I.I, Oliveira, MRM.3 1: Bariatric Clinic of Piracicaba, 2: FCFAR-UNESP; 3: IBB-UNESP Introduction Bariatric Surgery is most effective long term treatment for severe obesity. Exercises after surgery may improve physical fitness and additional metabolic benefits. However, there is a lack of consensus on performing physical activity (PA) in the postoperative and its effects on weight loss process and body composition. Methods Forty one women were divided into 2 groups: Exercise (EX;n=22):113,9Kg(11,6);161cm(4,9);34,2y(6,7); Sedentary (ST;n=19):111,1Kg(11,5);160cm (4,7);35,5y(8,6). All patients underwent gastric bypass Y-Roux (BGYR) without silastic band and made anthropometric measurements by bioimpedance analysis (Biospace, InBody 230®) before (T0) and 6 months after BGYR (T6), following the instructions established by the manufacturer. Were accessed: body weight (BW), body fat, lean mass and body water. At T6 were calculated for EX and ST in absolute and relative to the initial BW: weight loss; body fat loss, lean mass loss, body water loss. Patients were instructed to follow a postoperative diet and 2 months after BGYR EX were encouraged to do PA. EX and ST returned to the clinic monthly for nutritional monitoring and to respond to the questionnaires of PA. Normal distribution of the data was checked and the comparison between the variables used Student's t-test. Results EX performed aerobic PA (60min/ 3x wkl). Any significant difference ($p>0,05$) between EX and ST at T0 and T6 was found. All anthropometrics measurements decreased significantly T0 and T6 for both groups. Discussion There are two key issues regarding PA after BGYR and anthropometric changes: the possibility to accelerate or increase weight loss(Egberts et al,2012) and extending the loss of muscle mass due to greater energy expenditure under severe caloric restriction(Auclair et al,2016). The data presented here do not support none of the hypotheses showing any anthropometric difference between women engaged in PA and sedentary 6 months after surgery. One possible explanation is that the effects of bariatric surgery on weight loss and lean mass loss are quite relevant and the practice of PA is not enough to change or deepen this situation (Coen; Goodpaster, 2015). ADAPTATIONS IN MUSCLE MASS AND MOTOR FUNCTION DURING RESISTANCE TRAINING WITH ELASTIC BANDS AT DIFFERENT INTENSITIES IN OLDER ADULTS

GARGALLO, P.1, MUÑOZ, V.1, JUESAS, A.1, SAEZ, G.1,2, HERNANDO, A.2, IRADI, A.3, COLADO, J.C.1

University of Valencia

1: University of Valencia (Valencia, Spain), 2: Clinical Analysis, University Hospital Dr. Peset, (Valencia, Spain), 3: Physiology Department, University of Valencia (Valencia, Spain). Introduction Resistance training (RT) is an intervention frequently used to improve muscle strength and body composition in older adults (OA) (Chodzko-Zajko et al., 2009). Despite this, there is a lack of knowledge on how elastic resistance training (ERT) affects the muscle mass (MM) and motor function (MF) in this population. The purpose of this study was to determine the effects of ERT at different intensities on MM and MF in OA. Methods 121 OA (70.07 ± 5.12 years) were randomized into three groups: Control Group (CG) (n=45); High Intensity Group (HIG) (n=39); and Moderate Intensity Group (MIG) (n=37). A 16 weeks (WK) elastic resistance training (ERT) (TheraBand) program twice a WK was applied with 6 exercises. HIG were performed with 6 repetitions (REP) while MIG with 15 REP and both at intensity of 6-7 on the OMNI-RES perceived exertion for the first 4 WK and 8-9 the next 12. Total, upper, lower limbs MM and isometric strength (IS) were measured. Nonparametric tests were performed. Results The results showed significant improved in HIG and MIG respectively, comparing pre and post-training in total MM (+1.73 and +1.55%), upper limbs MM (+6.35 and +4.75%) and lower limbs MM (+2.99 and 2.64%). Regarding IS, HIG and MIG had significant improvements in vertical rowing (+38.71 and +46.19%, respectively) and horizontal leg press (+52.82 and 73.07%, respectively). Analysis between groups showed no significant effects. Discussion Our results could indicate that variables of prescription applied are not enough stimuli to provoke significant effects between intensities in OA and agree with previous studies (Borde R, Hortobágyi T, Granacher U, 2015; Martins et al., 2015). ERT are an effective method for improving MM and MF in OA but more research is necessary to identify the effect of different intensities in middle and long programs. THE RELATIONSHIP BETWEEN AMOUNT OF PHYSICAL ACTIVITY AND SLEEP HABITS IN UNIVERSITY STUDENTS

SASAKI, H.1, TAKAHASHI, M.2

1: Hokusho University (Ebetsu, Japan), 2: Japan Health Care College (Megumino, Japan)

Introduction It has been reported that people having some sleep problems is about 13% in Japan (Ministry of Health, Labour and Welfare, Japan, 2011). In addition, people who feel daytime sleepiness were 37.7% in male and 43.0% in female (Ministry of Health, Labour and Welfare, Japan, 2013). However, it has been reported that increased amount of physical activity improved sleep quality (King et al., 1997). On the other hand, it has also been reported that Japanese students had shorter sleep hours than the other countries (Steptoe A et al., 2006). The purpose of this study is to examine the relationship between amount of physical activity and sleep habits in university students. Methods Subjects in this study were 1,741 university students with a mean age of 19.9 ± 1.4 ($\pm SD$). We carried out a questionnaire from November to December 2011 and 2012. The questionnaire was composed of personal profiles, Life-style, including physical activity and sleep habits. In this study, it was classified people performing habitual physical activity into three levels by physical activity minutes per week; under 120 minutes (under 120), under 600 minutes (under 600) and over 600 minutes (over 600). Sleep quality was assessed by Japanese version of Pittsburgh Sleep Quality Index (PSQI-J). Lower sleep quality was assessed by using a cutoff total score point of >5.5. Daytime sleepiness also was assessed by Japanese version of Epworth Sleepiness Scale (JESS). Statistical analysis used SPSS ver.21.0. Statistical analysis used by analysis of variance, χ^2 test, Mann-Whitney U-test and correlative analysis and multiple. Results The amount of physical activity divided into four categories, those were non-habitual, under 120, under 600 and over 600 minutes per week. We compared with those four categories for male and female respectively. Compared with four categories, ratio of non-habitual students increased according to grade year rises in male and female. In male, there were significant differences in weight, BMI and points of JESS. The under 120 was lower than the other categories in the points of JESS. The under 120 group had a tendency to later the time of getting up than the other categories. In female, the over 600 was significantly shorter than the other categories in hours to fall asleep. Discussion It became clear that there were differences of male and female in the relationship between amount of physical activity and sleep habits. In female, increased amount of physical activity improved sleep latency, but not improved in male. In male, increased amount of physical activity increased daytime sleepiness because of earlier getting up time in the morning. It was suggested that the amount of physical activity was not necessarily related to sleep quality in university students. EFFECTS OF GROUP EXERCISE CLASS FOR REGIONAL ELDER PEOPLE HELD AT THE UNIVERSITY ON FUNCTIONAL FITNESS AND HEALTH-RELATED QUALITY OF LIFE

ISHIZAKI, S.1, HAMANO, M.1, UBUKATA, K.1, NEGISHI, T.1, ISHIZAKI, J.2, INAYAMA, T.3, NAITO, H.4

1) Shibaura Institute of Technology, 2) Japan university of health sciences, 3) Tokyo metropolitan university, 4) Juntendo university

Purpose The purpose of this study was to investigate the effect of regional elder people on functional fitness and health-related quality of life (HRQOL) in group exercise classes held at the university. Methods Twenty-nine healthy people (age; 69.0 ± 3.4 years, men; n=13, age; 70.2 ± 2.6 , female; n=16, age; 68.0 ± 3.6 years) volunteered to participate in this study. Subjects participated in 8-week group exercise class (90min./d, 2times/week, total 16 sessions). This exercise program consisted of 15 min. of warm-up and stretching, 20 min. of resistance exercise, 10 min. of step exercise, 20 min. of endurance-type exercise (walking), 20 min. of ball exercise (recreation), and 5 min. of cooling down. All exercise session was led by trained fitness instructors and supervised by the researchers. After the every exercise session, subjects were recorded Borg scale. Before (pre-) and after (post-) the group exercise classes, the following physical performances were measured; hand grip strength (HG), chair stand (CS), arm curl (AC), sit-up (SU), timed up & go (TUG), sit & reach (SR), back scratch (BS), functional reach (FR), 10-m walking (10-mWK), 10-m obstacle walking (10-mOWK) and 6-min walking (6-MW). In addition, blood pressure, brachial-ankle pulse wave velocity (baPWV), body composition, blood property, and 36-item Short Form Survey (SF-36) were measured before and after the course. Results Participation rate of the group exercise class was $88.3 \pm 8.9\%$. Borg scale in the exercise class was

11.7±0.3. Although there were not significantly changed in body weight, %fat, fat, and lean body mass, waist circumference significantly decreased from pre to post exercise class ($p<0.05$). Total cholesterol ($p<0.001$), low-density lipoprotein cholesterol ($p<0.01$), and triglyceride ($p<0.001$) were significantly decreased after the exercise. Systolic blood pressure and baPWV was significantly decreased after the exercise ($p<0.05$). Additionally, HG, CS, AC, SU, SR, BS, and 6-MW were significantly increased after exercise class. Time of TUG, 10-mWK, and 10-mOWK were significantly decreased after exercise class. On the other hand, FR was not significantly changed from pre to post exercise class. Physical functioning, vitality, and mental health in SF-36 were also significantly increased after the course. Conclusion In conclusion, this study demonstrated that group exercise classes for elder people living in that region provides improvement of functional fitness and HRQOL. References 1) Helbostad, J. L., Sletvold, O., Moe-Nilssen, R., Effects of home exercises and group training on functional abilities in home-dwelling older persons with mobility and balance problems. A randomized study. COULD CURIOSITY TRIGGER WELL-BEING THROUGH SPORT EVENT?

LU, W.C.1, KUO, C.C.2, LIN, S.H.3

1.National Taiwan University 2. National Taiwan Sport University 3.Hsuan Chuang University

Introduction While most studies have examined the factors to motivate or influence fans behavior relate to sport, only a few research has investigated what antecedents initially attract people to consume sport and further shift a nonfan to a loyal fan (Park, Mahony, & Kim., 2011). Accordingly, This study focus on sport fan curiosity as the antecedent of satisfaction with event and psychological well-being. Methods Data was collected from spectators participating in a quasi-professional volleyball game held in Taiwan. During the first wave of survey, 204 completed questionnaires were returned with a response rate of 85%. After game was over, a follow-up online questionnaire with the satisfaction-with-event and psychological well-being measures was delivered to the participants at first-wave by e-mail. The final respondent consisted of 172 spectators (97 female) with a mean age of 21.85 years ($SD = 5.30$). Results As the result presented, SPFCS had a significant association with SWE (a path; $B = .17$, $SE = .08$, $t = 2.22$, $p < .05$), supporting Hypothesis 1. In Hypothesis 2, we suggest that SWE positively associates with the change in PEAQ. Result showed that SWE had a significant relation with the change in PEAQ. (b path; $B = .43$, $SE = .06$, $t = 7.21$, $p < .01$). Thus, the Hypothesis 2 was supported. Finally, we propose the positive relation between SFECS and the change in PEAQ would be mediated by SWE. Supporting Hypothesis 3, we found that SFECS had a significant and positive indirect effect on the change in PEAQ (c path; $B = .14$, $SE = .07$, $t = 2.14$, $p < .05$). Discussion Supporting the proposed model, results of the study showed that sport fan curiosity has a positive association with satisfaction with event, which in turn enhanced psychological well-being. The study provided reliable evidence to contribute our knowledge about how sport fan curiosity has an influence on psychological well-being. Overall, the current findings further provided practical implications for fans' behavior in sport context. Reference Park, S. H., Mahony, D. F., & Greenwell, T. C. (2010). The measurement of sport fan exploratory curiosity. Journal of Sport Management, 24(4), 434-455.

INVESTIGATING THE FACTORS OF BAD POSTURE.

OHTA, M.

Chukyo University

【Introduction】 Children having bad posture has been concerned for the last several years. Several in elderly people studies have been conducted on the relationship between backward curvature and muscle strength1), or the relationship between balance ability and muscle mass2). The child who has a bad posture infers that their skeletal muscle mass and/or muscle strength to support a body are not enough. Thus, the purpose of this study was to clarify the effect of muscle strength, skeletal muscle mass and physical activity level on creating posture in children. 【Methods】 Ten healthy Japanese girls (age:14.1±0.9 yr, height:157.4±5.0 cm, weight:52.5±6.6 kg) voluntarily participated in this study. Pictures in a natural standing posture were taken from the front and the right side. Anatomical landmarks were digitized by using image analyzing system. The position of the center of gravity and foot pressure for 30 seconds were measured. Skeletal muscle mass was estimated by body composition analyzer by using bio-electrical impedance. Muscle strength in trunk and physical activity level of daily living were measured. 【Results & Discussion】 It was indicated that the center of gravity inclined toward the back when there was less muscle mass of the leg ($r = -0.791$, $p = 0.006$) . In addition, the smallness of leg muscle mass is associated in some way with the degree of the forward head posture ($r = 0.662$, $p = 0.037$). Then, the subjects were divided into a good posture group and a bad posture group. The foot pressure, the skeletal muscle mass, the muscle strength and the physical activity level had no significant differences between the two groups. These results suggested the possibility that the correctness of posture is affected by trunk and leg muscle mass, but not by the physical activity level. 【References】 1) Aida et al. (2005). EXERCISE COMBINED WITH MILK INTAKES SUPPRESSES MORBIDITY AND SYMPTOMS FOR UPPER RESPIRATORY TRACT INFLAMMATION DURING WINTER IN ELDERLY INDIVIDUALS

MURATA, H., SHINOHARA, M., ISHIHARA, T., KURODA, Y., TOMABECHI, N., MIZUNO, M.

Hokkaido University

INTRODUCTION: Regular moderate physical exercise causes a reduction in morbidity rates for upper respiratory tract inflammation (URTI) among athletes. A daily intake of milk has shown to increase in immune function among elderly individuals. A combined effect of regular physical activity with daily milk intakes on URTI is, however, unclear. This study aims at evaluating the combined effects of bowling exercise and milk intakes on salivary immunoglobulin A (sIgA) concentrations and the morbidity rate and symptom of URTI during winter in elderly individuals. METHODS: The number of 36 healthy individuals (15 males and 21 females, 54-74 yr) were participated, and 13 subjects (4 males and 9 females; 56-69 yr) completed. The subjects performed 2-hour bowling games once a week for 12 months from April to March of the following year. The subjects were randomly divided into two groups, (1) MILK ($n = 5$); those who took a 500 mL-milk during 3-game bowling, (2) SPORT ($n = 8$); those who took a 500 mL-sport drink during 3-game bowling. The sIgA concentrations were determined 3 times during pre-winter (April-September) and winter (October-March). The amounts of physical activities and daily milk intakes were assessed by the IPAQ-SV and questionnaire, respectively. Averages of determined variables for each season were calculated and used for the analysis. The rate of morbidity and the level of symptoms for URTI were recorded once a week for 6 months, and an average

during winter was calculated. Non-parametric evaluation of statistical analysis was used, and a level of 5% was considered to be significant. RESULTS: The slgA concentration decreased significantly from the pre-winter to the winter in the SPORT, ($205.27 \pm 43.66 \mu\text{g/ml}$ to $126.42 \pm 24.54 \mu\text{g/ml}$, mean \pm SEM) [z = 2.75, p < 0.01]; however, no such decline was detected in the MILK ($137.06 \pm 33.10 \mu\text{g/ml}$ to $121.38 \pm 20.56 \mu\text{g/ml}$) [z = 0.85, p = 0.40]. Neither the amount of physical activity nor that of daily milk intakes differed between the groups as well as the seasons. The morbidity rates of URTI were significantly lower in the Milk than the SPORT (0.4 times vs. 1.5 times) [z = 2.41, p = 0.02], and the total points for symptom levels were also significantly lower in the MILK than the SPORT (9 points vs 19 points) [z = 2.81, p < 0.01]. DISCUSSION: This study may provide an evidence to suggest that regular mild sports activities lasting for 2 hours combined with a 500 ml milk intake reduce morbidity rates and symptoms for upper respiratory tract inflammation during winter in elderly individuals. CHILDREN'S GUIDED ACTIVE PLAY: A NOVEL APPROACH USING SELF-PACED GAMES TO ESTABLISH PHYSICAL ACTIVITY PROGRAM TARGETS

BELCASTRO, A.

York University

INTRODUCTION: It is well recognized that children's physical activity (PA) participation is below recommended guidelines. Furthermore the rates of PA participation decline from childhood to adolescence, with girls having greater declines than boys. It was suggested that active play, compared to PA with sport-specific skills, might be an effective format to engage children in being physically active. To achieve health and fitness benefits from active play programs, they must be of sufficient intensity and prescriptive in nature. The purpose of this study was to investigate the potential of using children's self-paced games in determining the 'dose' of physical activity for children when participating in an active play program. METHODS: Study one - Children (n=34; 8-12yrs) participated in one-hour active play sessions (n=5) that included age-appropriate cooperative games (33). Each of the cooperative games was classified by ACC outputs (vectors (v)), as well as estimates of metabolic equivalents (MET) and percent time at moderate-vigorous activity (%MVPA), into light, moderate and vigorous games (p<0.05). Study 2 - the cooperative games were used to prescribe physical activity intensity levels during an eight-week children's active play program (1h/d; 5d/wk). Children's (8-12yrs; n=25) PA participation was measured in wk-1 (i.e., baseline (PA-BL)). Weekly PA targets (i.e., 10-30% percent above PA-BL) were randomly assigned for wk-2 to wk-8. RESULTS: Calibrated accelerometers (ActiGraph GT3X+) assessed the suitability of prescribing children's self-paced games during active play program on achieving PA targets. PA for children's self-paced games (study one) averaged 3600 ± 385 cnts/min and 4.1 ± 0.6 MET for all games (n=33) (range 1142-5169 cnts/min (p<0.05); and 2.5 to 6.5 MET (P<0.05)). Heart rates ranged from 115-158 bpm (p<0.05); mean of 138 ± 17 bpm (66%HRmax). For study two the PA-BL averaged 140,327 cnts/session over wk-1. PA participation ranged from 159,795 to 185,087 cnts/session from wk-2 to wk-8 (p<0.05); mean of $169,669 \pm 13,556$ cnts/session. PA targets for wk-2 (i.e. >20% of PA-BL), wk-3 (i.e., between 10-20% PA-BL) and wk-4 (i.e., <10% of PA-BL) were on average 2%, 1.5%, and 1% of prescribed PA levels (p>0.05). For wk-6 to wk-8 achieving PA targets (of >20%; <10%; 20-30% above PA-BL) were -31%, -0.5% and -18% when compared to PA-BL (p<0.05). CONCLUSION: Children's self-paced games can be used to prescribe the 'dose' of PA during active play programs. Funding: Faculty of Health, York University – Grants-in-Aid

IRISIN LEVELS IN THE BLOOD OF WOMEN OF DIFFERENT BODY MASS UNDER FASTING CONDITIONS AND AFTER A 10-MINUTE EXERCISE

MURAWSKA-CIAŁOWICZ, E.I., GOLINSKI, D.I., ZUWALA-JAGIELLO, J.Z., WOLANSKI, P.I.

(1) University of Physical Education, Physiology and Biochemistry Department, Wrocław, Poland; (2) Medical University, Department of Pharmaceutical Biochemistry, Wrocław, Poland

Irisin is called an effort hormone. It is a product of proteolytic cleavage of FNDC5 (fibronectin type III domain containing protein 5). It takes part in the body's metabolism regulation and intensifies oxidation of glucose and fatty acids. In adipose tissue it increases the expression of UPC-1 with PGC-1 alpha and takes part in the conversion of white adipocytes into brown ones (browning). It is a myokine secreted by muscles during physical exercise and an adipokine released by white adipose tissue. An increase in the expression of FNDC5 was also noticed in the hippocampus of mice subjected to endurance exercise and it was concluded that PGC-1alpha and FNDC5 regulate the expression of BDNF in the brain, a substance that participates in neuroplasticity. In the prevention of age-related diseases (e.g. dementia) or ones caused by obesity, e.g. diabetes mellitus type II or cancers and in treatments which make use of physical activity, it is important to determine irisin levels and their changes due to physical effort in the blood of obese people. Despite our knowledge of molecular mechanisms of irisin, changes in its levels in the blood after exercise are not clear or sufficiently documented. The aim of the study was to assess changes in irisin levels in the blood of women of different age and body mass, under fasting conditions and after physical exercise. The women were subjected to a 10-minute single exercise on a cycloergometer with a workload of 100W and 70-80 rpm. VO₂max was determined with the Astrand-Ryhming test. Before exercise (under fasting conditions) and 15 minutes after its completion the subjects had their blood taken from the basilica vein in order to assay their irisin levels. Body mass and composition were also analyzed. Irisin levels were correlated with age, body mass and body composition. On the basis of the obtained results it was stated that irisin levels are correlated with body mass, %fat in the body and they also depend on the subjects' age. While regulating the expression of BDNF, irisin can affect cognition, which is suggested by its correlation with age and body composition parameters observed in our studies. Taking into account prevention of obesity and diseases within the diseasesome of physical inactivity which correlate with age, but which are at the same time a result of low level of physical activity, it is a vital piece of information not only in terms of research but also its practical application. THE ATTITUDE OF STUDENTS TOWARDS THEIR HEALTH: MODERN TENDENCIES AND BEHAVIOURAL RISKS

FYODOROV, A., SIVOKHIN, I.

South Ural State University

Introduction In recent years, the problem of studying the health of students and their attitudes towards their health to pay close attention of many researchers. The urgency of this problem is determined by the fact that the students are of great importance in formation the social, labor and reproductive capacity of our countries. The purpose of research – to perform analysis the indicators that characterize attitude of students towards their health in context of behavioural risks. Methods Research was carried out within the framework of the research project «Physical Activity and Health of Students» in 2010-2014. The study involved students the following educational institutes: Ural State University of Physical Education, South Ural State University (Chelyabinsk, Russia), Kostanay State Pedagogical Institute (Kosta-

nay, Republic Kazakhstan). In total in research have taken part 840 person. Results It was found that upon reaching the age of 15, many students have tried smoking (at least once smoked cigarettes) – 54.2% of boys and 36.1% girls. By 15 years of age the vast majority of students at least once in his life tasted alcohol. 15.3% of boys and 4.9% of girls said they had at least once in their life have tried drugs. Students have relatively low level of physical activity. Only 15.3% of boys and 13.1% of girls are engaged in physical exercise a daily. Discussion / Conclusion Unstable social, economic and socio-cultural situation, which is typical of modern society exacerbates this tendency leads to the fact that about 70% of students in a state of prolonged psycho-emotional and social stress. Negative external factors contribute to the depletion of the body's adaptive capabilities lead to a breakdown of the mechanisms responsible for the preservation of health. References 1. PHYSICAL TRAINING AND THE BLOOD PRESSURE OF UNMEDICATED HYPERTENSIVE WORKERS

MELLO, A.M., SERRA, R.A., SIMÃO, R.

UF RJ - Universidade Federal do Rio de Janeiro

INTRODUCTION The employees' health is the concern of large corporations. A Brazilian company has been promoting a fitness program for eleven years oriented by the School of Physical Education at Universidade Federal do Rio de Janeiro, Brazil. As part of the risk factors control for non-transmissible chronic diseases, physical exercises are recommended for the prevention, treatment and control of blood pressure (BP). The aim of this study was to investigate the BP behavior after four months of training in unmedicated hypertensive subjects. **METHODS** Sixty-four sedentary subjects participated in the program (time ≥ 1 year), divided into a training group (TG) and a control group (CG). All were physically assessed and the TG had three sessions per week, totaling 48 sessions, each lasting 60 minutes. They performed a 25-minute aerobic training between 50 to 70% of heart rate reserve, a strength training in two series ranging from 8 to 12 repetitions, and a flexibility training applying the static stretching method. BP was measured by auscultation at pre- and post training and data were processed by two-way ANOVA using the Scheffé post hoc when needed ($p < 0.05$) for intragroup and intergroup comparison. **RESULTS** The intragroup outcome for the TG showed an 11.4% reduction in systolic BP (SBP) ($P < 0.05$) and 5.3% in diastolic BP (DBP) ($P > 0.05$). The CG showed no changes in BP ($P > 0.05$). Comparing CG and GT, there was a significant difference in SBP in post-training situation, but this did not occur in other measurements. **DISCUSSION** Studies confirm the hypotensive effect after aerobic work (Pescatello et al., 2004), but few have investigated the post-exercise strength hypotension. Martins et al. (2004) followed medicated hypertensives subjected to strength, aerobic and flexibility sessions and after eight weeks they found no significant differences regarding the resting values in both groups; however the BP in the TG showed a tendency to reduction. Despite the methodological differences between our experiment and Martins and co-workers', we found higher reductions in BP, probably because our sample was not medicated and training lasted 16 weeks. With measurements taken 48 hours after the last session aiming to decrease the acute hypotensive effect immediately after exertion, we found a clinically significant reduction in BP at rest. **REFERENCES** Martins ACS, Nogueira BRML, Couto FVP, Nicolau MSB, Pontes FL, Simão R, Polito MD. RELATIONSHIPS BETWEEN SERUM ADIPONECTIN LEVELS AND MUSCULAR FITNESS IN PORTUGUESE ADOLESCENTS: LABMED PHYSICAL ACTIVITY STUDY

AGOSTINIS SOBRIHO, C., MOTA, J., OLIVEIRA-SANTOS, J., MOREIRA, C., ABREU, S., ROSÁRIO, R., LOPES, L., SANTOS, R.

University of Porto

Do Introduction: Paradoxically, recent investigations have showed that adiponectin levels are inversely associated with muscle strength. However, to date, there is a lack of knowledge on the relationship between muscular fitness (MF) and adiponectin levels in adolescents. We aimed to examine the independent associations of MF and adiponectin levels in adolescents, controlling for several potential confounders. **Methods and Results:** This is a cross-sectional analysis with 529 Portuguese adolescents aged 12-18 years. A MF score was computed as the mean of the handgrip strength and standing long jump standardized values by age and gender. We measured fasting glucose, insulin, HDL-cholesterol, C-reactive protein and adiponectin. Linear regression analysis showed a significant inverse association between adiponectin (Z-score by age and sex) and MF score, after adjustments for age, sex, pubertal stage, socioeconomic status, adherence to the Mediterranean diet, body mass index, HOMA-IR, HDL-cholesterol, C-reactive protein and cardiorespiratory fitness (unstandardized $\beta = -0.176$; $p < 0.005$). Analysis of covariance showed a significant difference between the Low MF/Non-overweight group and the High MF/Non-overweight Group ($p < 0.05$) and between the Low MF/Non-overweight and High MF/Overweight Group ($p < 0.05$) ($F(5, 523) = 2.262$, $p = 0.047$). **Conclusion:** Adiponectin circulating levels are inversely and independently associated with MF

RELATIONSHIP BETWEEN DAILY PHYSICAL ACTIVITY, PHYSICAL FITNESS AND LIFESTYLE HABITS IN ELEMMENTARY SCHOOL CHILDREN

MURAOKA, Y.I., KAIDO, M.2, SASAHARA, C.1, IMAFUKU, K.1

1 Meisei Univ (Tokyo, Japan), 2 Hachioji Dairoku Elementary School (Tokyo, Japan)

Introduction: In Japanese children, although their physical fitness has been getting better gradually in the last decade, it is still lower than their parents' physical fitness. It is worth surveying the background of physical fitness in the children in order to solve this problem. The purpose of this study was to assess the daily physical activity in Japanese elementary school children and to analyze the relationship between daily physical activities and physical fitness or lifestyle habits. **Methods:** Subjects were 164 elementary school children (3rd grade; 68, 5th grade; 96) in Tokyo. Daily physical activities (steps, amount of physical activity, activity time, total energy consumption, exercise strength) were assessed in eight successive days using a uniaxial accelerometer (LifeCorder EX; Suzukawa Co., Japan). The subjects performed a physical fitness test including grip strength, one-leg balancing, 20m shuttle-run, sit-ups, side-to-side jump, forward standing jump, hamstring and lower back flexibility softball throw, and 50m run. The lifestyle was assessed using questionnaires. **Results:** The total energy consumption, amount of physical activity and steps per day showed significantly higher values in boys than girls for both grades ($p < 0.01$). The steps per day were significantly higher in 3rd grade than 5th grade for boys and girls ($p < 0.01$). The steps per day of the children who belong to sports clubs were 1500 steps more compared to the children who don't belong to sports clubs ($p < 0.01$). Tele-

vision view time and breakfast intake did not show significant correlation with the physical activities. 20m shuttle-run was correlated positively with steps per day in the 5th grade boys ($p<0.05$). Discussion: Daily physical activities such as steps per day tend to decrease with grade, which is remarkable for girls. The children who participated in sports club showed significant greater steps per day. Therefore, for the elementary school children in this study, participating in sports clubs may contribute to increase physical active mass in weekdays. Contact: muraoka@ge.meisei-u.ac.jp

BREAKS IN SEDENTARY TIME AND MUSCULAR FITNESS IN PORTUGUESE ADOLESCENTS: A LONGITUDINAL ANALYSIS FROM THE LABMED STUDY.

SANTOS, R.1,2, LOPES, L.1,3, MOREIRA, C.2, ABREU, S.1, OLIVEIRA-SANTOS, J.1, AGOSTINIS, C.1, OLIVEIRA, A.1, ROSÁRIO, R.4, PÓVOAS, S.5, SILVA, P.1, MOTA, J.2

1: Early Start Research Institute, UOW (Australia), 2: CIAFEL-FADE, UP (Portugal), 3: Research Centre in Child Studies, UM (Portugal), 4: Health Sciences Research Unit, UC (Portugal), 5: CIDESD (Portugal).

Introduction Low levels of muscular fitness (MF) seem to be associated with an adverse metabolic and inflammatory profile in children and adolescents. It has been reported that cardiorespiratory fitness is independently associated with physical activity and sedentary time in adolescents; however, the information about the associations of MF is scarce. This study aimed to verify if the associations between changes in breaks of sedentary time and MF changes are independent of physical activity levels, over a 2-year period, in Portuguese adolescents. The sample comprised of 225 children (56.9% girls) aged 13.59 ± 1.46 at baseline, from the LabMed study (2011-2014). Sedentary time and physical activity were measured with accelerometry and MF with the Long Jump and Handgrip tests. Accelerometer counts, lasting at least 1 min, above 101 counts per min were defined as a break in sedentary time. A MF score was created from the sum of age and sex adjusted z-scores from the average Handgrip and Long Jump tests. Linear regression models were fitted to assess β and 95%CI predicting MF changes, adjustments included age, sex, accelerometer wear time at baseline and follow up, MF score at baseline, changes in total moderate-to-vigorous physical activity, changes in total sedentary time, changes in maturation status and changes in BMI. Results Results showed that, over a 2 year period, breaks in sedentary time decreased from on average from 20.6 ± 8.6 /day to 17.7 ± 9.3 /day ($p\leq0.001$); however, changes in sedentary time breaks were positively related with changes in muscular fitness, after adjustments for the above-mentioned confounders $\beta=0.020$ (95%CI:0.002-0.037); $p=0.029$. Discussion This study suggests that increasing breaking sedentary time is positively related with increases in MF during adolescence, regardless of changes in total sedentary time, moderate-to-vigorous physical activity and other potential confounders. OBJECTIVELY MEASURE SEDENTARY TIME AND ACADEMIC ACHIEVEMENT IN SCHOOLCHILDREN

LOPES, L.1,2, SANTOS, R.1,3, MOTA, J.1, PEREIRA, B.2, LOPES, V.P.4

1: CIAFEL-FADEUP (Porto, Portugal), 2: CIEC-UMinho (Braga, Portugal), 3: ESRI-UOW (Wollongong, Australia), 4: CIDESD-IPB (Bragança, Portugal)

Introduction A healthy lifestyle is essential for students to achieve their full academic potential, mental growth, lifelong needs, health and well-being. The deleterious health effect of sedentary behaviour on cognitive outcomes in children and adolescents has been explored, but results are inconsistent and the factors underlying these associations are not fully understood. This study aimed to evaluate the relationship between objectively measured total sedentary time and academic achievement in Portuguese children. Methods The sample comprised of 213 children (51.6% girls) aged 9-10 (9.46 ± 0.43) years, from the north of Portugal. Sedentary time was measured with accelerometry and academic achievement was assessed using the Portuguese Language and Mathematics National Exams results. Multilevel Poisson Regression models were fitted to assess rate ratios predicting academic achievement, adjustments included accelerometer wear time, age, gender, body mass index, socioeconomic status, mother education level, moderate-to-vigorous physical activity, cardiorespiratory fitness and motor coordination. Results Results showed that the relationship between academic achievement and sedentary behavior was curvilinear with an inverted U shape, although not statistical significant [Rate Ratio:1.006 (95% CI: 0.967-1.046); $p=0.960$]. Discussion To perform academically, children may need a certain amount of sedentary time (probably spent on school-related pursuits such as homework, reading or studying), but additional sedentary time may be detrimental to academic success. This study suggests that objectively measured total sedentary time was not associated with academic achievement, after adjusting for potential confounders. Contact: luis.iec.um@hotmail.com

PHYSICAL FITNESS AND COGNITIVE FUNCTION OF COMMUNITY-DWELLING ELDERLY FEMALE PARTICIPATING IN A SQUARE-STEPPING EXERCISE CLUB- COMPARISON ACCORDING TO NUMBER OF YEARS OF PARTICIPATION –

NAKAGAICHI, M.

School of Health Sciences

Introduction With the aging of the population in recent years, there are high hopes for activation of local communities focusing on resident-led exercise activity. The authors have fostered an autonomous club for practicing Square-Stepping Exercise (SSE) at least twice per month from the viewpoint of care prevention. Many previous studies on the effects of autonomous exercise clubs have investigated levels of satisfaction with questionnaires or used surveys to investigate subjective healthiness. In contrast, few studies have conducted cross-sectional or longitudinal investigation of Physical fitness and cognitive function. Therefore, the purpose of this study was to cross-sectionally compare whether community-dwelling elderly female participating in a SSE club exhibited different effects on physical fitness and cognitive function depending on the number of years they had been participating in the club. Methods The subjects in this study were elderly females who could conduct their lifestyles independently and were continuously participating in an SSE club. The SSE club in this study was a group that conducted SSE and was operated autonomously by local residents. Physical fitness was evaluated according to the five items of grip strength, standing on one leg with eyes open, sitting down and standing up for 30 seconds, walking in a figure of eight and moving beans with chopsticks. Physical fitness age was calculated using formula created by Nakagaichi et al. Cognitive function was evaluated using the Five-Cog Test developed by Yatomi et al. Results No significant differences were noted in the items for physical fitness. However, physical fitness age was significantly younger in the 5 years group compared to the 1 year group. On the other hand, there was no significant difference in cognitive function testing among each group. Conclusion To participate in the SSE club on the long-term has been suggested that improve physical fitness for elderly female. However, it was not obvious for the improvement of cognitive function.

History

CHRONOLOGICAL TABLE ABOUT ELEMENTS FOR PARALLEL BAR PERFORMANCE IN MEN'S ARTISTIC GYMNASTICS "ANALYSIS FROM JAPANESE JOURNALS"

NAKASONE, M.

university of Biwako Seikei sport

Introduction Currently, more than 100 elements on the Parallel Bar (PB) have been recorded in the Gymnastics Code of Points. However, we wonder by whom, when or where these various elements are performed. The purpose of this study was to collate data elements on the PB in men's artistic gymnastics and to suggest new elements in the future. Methods The method of study was undertaken by bibliographic analysis. This article refers mainly to journals that were published by the Japan Gymnastic Association, and a list that was made regarding the occurrence of new elements on PB in men's artistic gymnastics. Results From the analysis, the author gathered data regarding various elements that were performed. For example, the Swing forward with 1/1 turn to uprise arm hang was performed by CARMINUCCI G (ITA) in the 1971 World Championships. Moy piked with straddle backward to handstand was performed by TIPPELT S (GDR) in the 1989 World Cup and Moy piked with straddle backward to handstand was performed by TIPPELT S (GDR) in the 1989 World Cup and Swing forward, straddle cut backward, and regrasp with straight body at horizontal was performed by BHAVSAR R (USA) in the 2009 World Cup. These elements are performed by many top male gymnasts. Bent arm swing forward to hop 1/2 turn to support was performed by KATO S (JPN) in the 1976 Olympics and Forward uprise to Kato hop to support was performed by WATANABE M (JPN) in the 1983 World Championships. Double salto forward piked dismount was performed by BELYAVSKIY D (RUS) in the 2011 World Championships. Basket with 5/4 turn to handstand was performed by ZHOU S (CHN) in the 2012 Asian Cup. Discussion In conclusion, directions of new occurring elements on the PB may add twists or salto to the existing elements. Developments of PB elements are greatly influenced by rules of the era, change of the apparatus height level, and improved skills of men's gymnastics. Future, we will make it clear directions of new elements to pay attention to changes to the Men's Code of Points. CHANGES IN HGF LEVELS AFTER A PROGRESSIVE TEST BEFORE AND AFTER A TABATA HIIT PROGRAM

WOLANSKI, P., GOLINSKI, D., ZUWALA-JAGIELLO, J., KLICH, S., WIERZBICKA-DAMSKA, I., MURAWSKA-CIALOWICZ, E.

University of Physical Education in Wrocław

Introduction: HGF (hepatocyte growth factor) is a growth factor of mesenchymal origin which activates satellite cells participating in the regeneration of damaged muscle fibres. It fulfils many biological functions, it is a mitogenic (stimulates cell division), motogenic (enables cell migration), morphogenic (facilitates cell differentiation), and angiogenic factor (stimulates formation of blood vessels). It acts in an auto-, para – and hemocrine manner. Due to its participation in regeneration of different cell structures, HGF is being tested for use as a medicine administered in medical conditions accompanied by organ damage. HGF can be of systemic origin (secreted by the lungs, liver, kidneys), or of muscle origin – secreted by fibroblasts in the muscles. Although a lot of research has been done into HGF and the role it plays in muscle regeneration and angiogenesis, little is known of changes in HGF levels in athletes in response to different types of effort. Aim: The aim of the study was to assess the changes in HGF levels after a progressive test on a treadmill before and after an 8-week Tabata HIIT program (high intensity interval training) done twice a week. Each training unit consisted of 7 sets of 4-minute-long workouts following the pattern of 20sek work/10sek passive break and 1min break between the sets. A group of women (n=8) and men (n=10) were involved in the study. HGF levels were assayed by the ELISA method. Results: HGF level measured 15 minutes after a progressive test increased in comparison to its resting values before and after an 8-week training program. Before the training, higher values of HGF were noted in women, after the training there were no differences. HGF at rest and after effort correlated with the parameters of acid-base balance – pH, BE and lactate level (LA) Discussion: A 2-month HIIT program did not cause an increase in HGF levels in the subjects' blood. However, an increase in its levels after a progressive test and correlation with pH and LA suggest that muscle acidosis could be one of the factors initiating the activation and increase in HGF levels in the blood. Wahl et al. (2014) also noticed an increase in HGF levels after a single HIT workout.

REGULAR MODERATE EXERCISE IMPROVES NON-ALCOHOLIC FATTY LIVER DISEASE INDUCED BY HIGH-FAT DIET VIA MONOACYGLYCEROL O-ACYLTRANSFERASE 1 PATHWAY SUPPRESSION

PARK, J.J., BAEK, K.W., OCK, M.S., CHA, H.J.

Pusan National University

Introduction: Non-alcoholic fatty liver disease (NAFLD) has been known to be dangerous as much as alcoholic fatty liver disease. NAFLD has a risk of developing steatohepatitis, fibrosis, cirrhosis and then eventually hepatocellular carcinoma, and therefore, this risk is increased with obesity. Recently, monoacylglycerol O-acyltransferase 1 (MGAT1) has been reported to play a key role in development of diet-induced NAFLD. Thus, this study was to investigate the effect of exercise on suppression of MGAT1 pathway in liver tissue of high-fat diet induced obese rats. Methods: The experiment was composed of 2 parts. In part 1 phase, 35 rats divided into 2 groups, normal diet group (ND, n=7) and high-fat diet group (HFD, n=28) to study the effects of high-fat diet on MGAT1 expression in liver tissue. In part 2 phase, the HFD group (n=21) was divided into control group (HFD-con, n=7), exercise group (HFD-exe, n=7) and diet shift from high-fat diet to normal-diet group (HFD-shift, n=7), to study the effects of exercise on MGAT1 suppression in NAFLD. Total experimental period was 12 weeks (6 weeks for each part). All the high-fat feeding rats were fed a high-fat diet (45% of total calories from fat). The treadmill exercise consisted of a 6-weeks accommodation phase with increasing exercise intensity (first, second, and third week: 15 m/min for 30, 45 and 60 minutes, respectively; fourth, fifth and six weeks: 20 m/min for 30 and 45 minutes, respectively), followed by a 5-weeks constant training period (20 m/min for 60 minutes). All running rats had a 5-minute warm-up phase with slowly increasing speed, before each training session (5 time a week between 5:00 and 6:00 pm). Lipid accumulation in liver tissue was determined by Oil Red O staining method. mRNA expressions of MGAT1 and liver fat synthesis related gene (PPAR γ , chREBP, SREBP1c) were measured by real-time PCR

(qPCR) and protein expressions were measured by Western blotting. Results The MGAT1 expression significantly increased by high-fat diet feeding (part 1). However, HFD-exe reduced mRNA expression of MGAT1. Both HFD-exe and HFD-shift also reduced protein expression of MGAT1. Notably, lipid accumulation in the liver reduced in both HFD-exe and HFD-shift group. Conclusions: These results suggest that the MGAT1 pathway suppression by regular moderate exercise is critically important in the treatment of NAFLD in diet-induced obesity.

HIGH INTENSITY RESISTANCE TRAINING REDUCES BODY WEIGHT AND MUSCLE MASS LOSS INDUCED BY ACUTE SLEEP DEPRIVATION

MÔNICO-NETO, M.1, LEE, K.S.1, PHILLIPS, S.M.4, GIAMPÁ, S.Q.C.1, SOUZA, H.S.1, DÁTILLO, M.1, DE MELLO, M.T.1,3, TUFIK, S.1, ANTUNES, H.K.M.1,2

Introduction Sleep deprivation (SD) increase hypothalamus-pituitary-adrenal axis activity, which results in negative energy balance, weight loss and muscle atrophy in rats (Mônico-Neto et al, 2015). Previous resistance training could minimize the catabolic effect induced by SD and preserve the body mass and muscle trophism. Thus, aim of this study is observe if trained rats by high intensity resistance training could minimize the deleterious effects on muscle mass and weight loss when submitted to SD. Methods Forty male Wistar were allocated into 1 of 4 groups: control (CTL), resistance training (RT), sleep deprivation for 96 hours (SD96), and RT followed by SD for 96 hours (RT+SD96). The protocol of exercise was performed during 8 weeks, 5 times/week. Forty-eight hours after last session of exercise, the RT group were euthanized and the RT+SD96 and SD96 groups were submitted to SD for 96 hours by modified multiple platform method (Sucheki and Tufik, 2000). Immediately after SD, were analyzed the corticosterone concentration, muscle trophism, and molecular markers of protein synthesis and degradation in muscle. Results The sleep deprivation induced body mass and muscle loss, increased corticosterone concentration and markers of protein degradation in muscle, as LC3, SQSTM1/p62, ubiquitinated proteins. In other hand, RT+SD96 minimized these changes and increased activity of protein synthesis pathway, as mTOR and p70S6k. Discussion High-intensity RT performed before SD contained muscle loss induced by SD. Moreover, increased activity of synthesis protein pathway and minimized the abundance of protein degradation pathway, minimizing the body's weight loss. These changes indicate that trained rats had better assimilation of stress induced by SD. References Sucheki D, Tufik S (2000). Social stability attenuates the stress in the modified multiple platform method for paradoxical sleep deprivation in the rat. *Physiol Behav*. Jan;68(3):309-16. THE IMPACT OF MODERATE-INTENSITY CONTINUOUS AND HIGH-INTENSITY INTERVAL TRAINING ON PLASMA miRNA PROFILE OF HYPERGLYCAEMIC PATIENTS

MORENO-ASSO, A.1, ELLIS, K.2, RAMOS, J.S.3, COOMBES, J.S.3, COOKE, M.1, STEPTO, N.K.1

Victoria University

AFFILIATIONS 1. Victoria University, Australia 2. University of WA, Australia 3. University of Queensland, Australia INTRODUCTION Exercise is highly beneficial in patients with type-2 diabetes (T2DM) for improving clinical risk factors like obesity and insulin resistance. However, the exact biological mechanisms that result in the improved clinical outcomes are not fully understood. Identifying potential biomarkers that are differentially regulated by exercise in T2DM, such as circulating microRNAs (miRNAs), and associating these responses with improved insulin resistance and other clinical risk factors, may offer new insights to optimise exercise prescription in individuals with T2DM. METHODS 26 men and 7 women with elevated fasting glucose ($>=6.1\text{mM}$) with and without T2DM completed 16wks of the following exercise programs: i) moderate-intensity continuous training (MICT, n=7, 30mins at 60-70% peak heart rate [PHR], 5x/wk); ii) high-volume high-intensity interval training (4HIIT, n=13, 4x4min intervals at 85-95% PHR, interspersed by 3mins active recovery, 3x/wk); iii) low-volume HIIT (1HIIT, n=13, 1x4min interval at 85-95% PHR). miRNA was extracted from resting blood samples taken before and after the 16wks intervention. Pre-selected miRNAs were detected by qPCR using Exiqon Kits and data were analysed with GenEx software. RESULTS Plasma abundance of mir-28-3p, mir-126-3p, mir-146a-5p, mir-27a-3p and mir-223-3p was decreased ($p<0.05$) in hyperglycaemic patients following MICT intervention. Only mir-34a-5p expression levels significantly increased ($p<0.05$) after 4HIIT, while no changes in plasma miRNA expression were observed after 1HIIT. DISCUSSION MICT caused a greater impact on the plasma miRNA expression profile than HIIT, significantly reducing the abundance of mir-28-3p, mir-146a-5p and mir-27a-3p, previously shown to be increased in T2DM patients [1]. MICT further reduced the expression of mir-223-3p and mir-126-3p, already found to be downregulated in the setting of T2DM [1] and that may play a role in glucose uptake and insulin resistance in peripheral tissues [2, 3]. Following 4HIIT, only mir-34-5p expression was increased, which has been associated to hypertriglyceridemia [4] and may suggest a negative effect of this intervention. Together, these data indicate that HIIT and MICT differentially alter the plasma miRNA expression profile in hyperglycaemic patients, which may mediate the different training-induced changes on the metabolism. Further studies considering healthy individuals will be addressed. REFERENCES 1. Zampetaki et.al. Circulation Research. 2010;107:810-817 2. Ryu HS et al. PLOS One. 2011;6(3):e17343 3. Lu et al. RESPONSES OF SKELETAL MUSCLE HYPERSTROPHY IN WISTAR RATS TO DIFFERENT RESISTANCE EXERCISE MODELS

DE SOUZA, C.T., LUCIANO, T.F., MARQUES, S.O., PIERI, B.L.S., NESI, R.T., SCHEFFER, D.L., COMIN, V.H., SOUZA, D.R., MULLER, A.P., PINHO, R.A.

University of Far South of Santa Catarina

Introduction Intense interest in the downstream molecular events by which mTOR signaling promotes cell growth have been emerged, however, the pathway of upstream mechanisms regulating mTOR needs more investigation, mainly molecules that directly modulated the mTOR. Thus, the aim of the present investigation was evaluated the effects of three different models of progressive resistance exercise based on climbing a ladder on the phosphorylation of mTOR and the upstream signaling. Methods Wistar rats (n=6 per group) were used as follow: untrained (C), endurance resistance training (ERT), strength resistance training (SRT), and hypertrophy resistance training (HRT). All animals were exercised in climbing a ladder (1.1 x 0.18 m, 30 2-cm-high steps, 80° slope). Forty-eight hours after the last training session, the animals were killed by decapitation and quadriceps muscle was collected for Western Blot and histology analysis. Results We observed a significant increase in the fiber cross-sectional area of all the exercised groups compared to sedentary. The exercised

groups increased mTOR phosphorylation and of the molecules that activate mTOR (i.e. PKB, 14-3-3, ERK, P38MAPK phosphorylation) when compared to untrained group. In addition, the increase of SRT was higher compared to ERT group, and the increase of HRT was higher mTOR phosphorylation compared to ERT. On the other hand, the protein levels of tuberin, REDD1 and SESN2, and the phosphorylation of AMPK (molecules that inhibit mTOR) were lower compared to the untrained group. Interestingly, these reductions were higher in the SRT compared to ERT, and in HRT compared to the other groups. Discussion The results showed that quadriceps weight and cross-sectional areas were higher in the exercised groups compared to untrained rats. However, the hypertrophy resistance training group presented better results compared to the other experimental groups. This same pattern was observed for mTOR phosphorylation and for the most pivotal molecules involved in the upstream control of mTOR (increased of PKB, 14-3-3, ERK, P38MAPK, 4EBP1 phosphorylation and reduction of Tuberin, Sestrin 2, REDD1 and p-AMPK). Our data demonstrated that the higher training intensity led to higher activation of the mTOR/PKB intracellular signaling and proteins that positively regulates this pathway while occur the inhibition of proteins that negatively modulate this pathway. Moreover, the HRT showed the higher increase on muscle hypertrophy as well as intracellular signaling activity. Contact ctsouza@unesp.net

SOCS3 ABALATION IN LEPTIN RECEPTOR-EXPRESSING CELLS INHIBITS GLUCONEOGENESIS AND PREDISPOSES MICE TO HYPOGLYCEMIA AFTER PROLONGED FASTING

PEDROSO, J.A., FURIGO, I.C., RAMOS-LOBO, A.M., TEIXEIRA, P.D.S., DONATO, J.J.R.

University of São Paulo, São Paulo

Introduction Leptin plays an important role in the regulation of glucose homeostasis during obesity. For example, inactivation of SOCS3 in leptin receptor-expressing cells protects mice from diet-induced insulin resistance (Pedroso, 2014). However, it is unclear whether leptin modulates glucose homeostasis during caloric restriction, which is condition in which gluconeogenesis is critical to support life. Methods Mice lacking SOCS3 protein specifically in leptin receptor (LepR)-expressing cells (LepR SOCS3 KO mice) were studied during fasting. To assess hepatic glucose production, a pyruvate tolerance test (PTT) was performed in LepR SOCS3 KO and control mice, either in fed and fasting (24 and 48h) conditions. To investigate the mechanisms involved in glucose homeostasis, we assessed the serum levels of hormones involved in the regulation of glucose homeostasis or used drugs to block the autonomic nervous system during the PTT. In order to inhibit the parasympathetic nervous system, we administered of 3 mg / kg of atropine (Sigma). Phentolamine (Sigma) (3mg / kg) and propanolol (Sigma) (0.5mg / kg) were co-administered to block the sympathetic nervous system. Results Fasting caused a reduction in serum glucose levels; however, control mice were able to sustain glycemia above 60 mg/dl avoiding hypoglycemia. On the other hand, LepR SOCS3 KO mice exhibited hypoglycemia after 48 h fasting. PTT results showed that LepR SOCS3 KO mice had suppressed gluconeogenesis, especially during prolonged fasting periods. No changes in serum levels of insulin, glucagon, growth hormone and corticosterone were found between groups during fed and fasting conditions. Additionally, hepatic glucose production remained lower in LepR SOCS3 KO mice even with the blockage of parasympathetic nervous system. However, after blocking the sympathetic nervous system, the differences between groups in the gluconeogenesis were no longer observed. Discussion Our results reveal that leptin modulates glucose homeostasis even during periods of caloric restriction. This regulation depends on the sympathetic nervous system. Although putative SOCS3 inhibitors can be beneficial for the treatment of obesity and diabetes, these drugs can produce undesired effects such as increase the risk of hypoglycemia during prolonged caloric restriction. These findings contribute to the understanding of possible side effects of drugs intended to increase leptin sensitivity for weight loss treatment. COMBINED EFFECTS OF 17-BETA-ESTRADIOL AND EXERCISE TRAINING PROTECTS AGAINST CARDIAC APOPTOSIS IN OVARIECTOMIZED RATS

LIN, Y.Y.1, YANG, A.L.2, LEE, S.D.1

1: China Medical University (Taichung, Taiwan); 2: University of Taipei (Taipei, Taiwan)

Introduction. Menopause-related estrogen-deficiency has been linked to the rapid increase in cardiovascular disease. 17 β -estradiol provides protection against cardiovascular disease. Moreover, exercise training is well known to prevention and treatment of cardiovascular disease. The purpose of this study was to evaluate the combined effects of 17 β -estradiol and exercise training on cardiac anti-apoptotic and pro-survival effects in ovariectomized rats. Methods. Fifty-six female Sprague-Dawley rats were divided into sham-operated group (Sham), and bilateral ovariectomized group (OVX), and OVX injected intraperitoneally with 17 β -estradiol (OVX-E2; 10 mg/kg/day), and OVX treated with 17 β -estradiol and exercise (OVX-E2-EX). 10 weeks after intervention, the excised left ventricle from rats were measured by histopathological analysis, TUNEL assays and Western Blotting. Results. The OVX group exhibited abnormal myocardial architecture, interstitial fibrosis and more cardiac TUNEL-positive apoptotic cells relative to Sham group. This situation became better after 17 β -estradiol alone or combination interventions. The OVX group exhibited decreased ER- α , ER- β , IGF-1, IGF-1R, p-PI3K, p-Akt, Bcl-2, Bcl-XL and p-Bad compared with Sham group. All of these changes were increased after 17 β -estradiol alone or combination interventions. The OVX group exhibited increased TNF- α , Fas ligand, Fas receptors, FADD, t-Bid, Bad, Bax, Cytochrome c, caspase-8, -9, and -3 compared with Sham group and this increase could be reversed by either 17 β -estradiol alone or combination interventions. Moreover, there are a partly additive effect on the upregulation of ER- β , IGF-1, IGF-1R, Bcl-2 and Bcl-XL as well as the downregulation of Fas, FADD, Cytochrome c, activated caspase-9 and activated caspase-3 in the OVX-EX-E2 group compared with the OVX-E2 group. Discussion. Our results indicated that combined therapies with 17 β -estradiol and exercise training could have an additive or synergistic effect in protecting against cardiac apoptosis through modulation of cardiac estrogen receptor related pro-survival and anti-apoptosis pathways in ovariectomized rats. It suggested that combination of 17 β -estradiol plus exercise training would ameliorate parts of cardiac function in the population of postmenopause. Refrance. CHRONIC RAPAMYCIN ADMINISTRATION FURTHER STRENGTHEN EXERCISE-INDUCED mRNA EXPRESSION OF PROTEIN INVOLVED IN ENERGY METABOLISM IN RATS FED A HIGH-FAT DIET

LIAO, B., HUANG, H., XIE, Y., HUANG, Z.

Guangzhou Sport University

Objective The mammalian target of rapamycin(mTOR) pathway is a critical signaling component in the development of obesity-related insulin resistance, but the precise mechanisms linking exercise-induced improvement of the insulin resistance and mitochondria oxidative metabolism in high-fat diet(HFD) rats remain unclear. Our aim was to investigate the role of the rapamycin (inhibitor of mTOR) on exercise-induced improvement of skeletal muscle gene involved in energy metabolism in HFD rats. Method 24 male SPF rats were fed with HFD for 6 weeks. After one week exercise adaptation, the rats were randomized to 4 groups (n=6):HFD+sedentary group(H group),HFD+exercise group(HE group),HFD+rapamycin (HR group), HFD+ exercise+rapamycin(HER group).The rats in HE group and HER group were performed exercise training for 4 weeks from the 8th week on and those in HR group and HER group received the intraperitoneal injection of rapamycin with the dose of 2 mg/kg/day for 2 weeks from the 10th week on. At the 11th week, the glucose tolerance and insulin tolerance tests were performed two days before the sacrifice of the animals. Finally, the rats were sacrificed after 12-16 hour fast. The soleus (SOL) and extensor digitorum longus(EDL) were harvested for analysis of activity of mitochondria oxidative enzyme and gene expression involved in energy metabolism. Result The exercises and rapamycin reduced the body weight and relative body fat ($P < 0.05$). Moreover, the exercises improved the glucose tolerance and insulin tolerance while the rapamycin aggravated these variables. Further analysis indicated that the exercise significantly improved the activities of succinodehydrogenase and cytochrome C oxidase (COX) in EDL of HFD rats, and significantly up-regulated the expression level of UCP2, PPAR α and COX4 mRNAs in EDL of HFD rats, but the rapamycin did not inhibit the expression of these genes. On contrary, rapamycin up-regulated the PGC-1 α and UCP2 mRNAs in EDL. Discussion Consistent with previous researches(Samuel et al, 2012 ;Houde et al, 2010),the exercises improves insulin tolerance, mitochondrial oxidative capability and mRNA level of genes involved in energy metabolism, and chronic rapamycin administration aggravates insulin resistance induced by HFD.Researches have shown that mTOR pathway promotes skeletal muscle mitochondrial oxidative metabolism.In the present study,rapamycin did not inhibit but strengthen exercise-induced up-regulation of skeletal muscle genes involved in energy metabolism in HFD rats. Motor Learning

VISUAL BIOFEEDBACK REDUCES FOREARM MUSCULAR ACTIVITY DURING PIANO OCTAVE STROKE

ISHIGAKI, T., KAKEYA, Y.

Aichi University of the Arts

Introduction Piano keystrokes are mainly performed with the muscles of the upper extremities. The octave keystroke (OKS), in which as the hand is spread widely, requires more muscular activity (MA) in the hand, especially in individuals with small hands. Real time viewing of electrical myogram (EMG) can be used to see MA during keystrokes. The aim of this study was to examine how MA during piano OKS was reduced by viewing real time EMG (RTEMG). Methods The subjects were five graduate students majoring in piano. The piano used for this experiment was a grand piano. The experimental task was to play fortissimo 8th OKS on each side. Surface EMG was used to measure and present the MA of subjects' upper body muscles (neck, shoulder, upper arms and forearms). EMG was sampled with 5-500 Hz band pass filters and 1000 Hz. The root mean squares of measured EMG was taken and integrated (IEMG) during the 500 ms of the before keystroke (pre and during keystroke: PDKS) and after keystroke (AKS) at the time of peak sound pressure. The biofeedback (BF) task was to consciously reduce the MA of the forearm by looking at the RTEMG. The effect of BF was evaluated by the ratio of IEMG when looking to that when not looking at RTEMG. Results In PDKS, the MA of the trapezius (range from -31.1 % to -5.0 %), biceps (range from -28.4 % to -2.2 %) and all forearm muscles (range from -31.5 % to -14.8 %) on both sides were reduced. However, the MA of both the deltoid and triceps were increased (range from +12.4 % to +41.4 %). In AKS, the MA of the right trapezius (-16.5 %) and all forearm muscles (range from -19.1 % to -4.8 %) was continuously reduced but that of the deltoid (+22.6 %), biceps (+40.7 %) and triceps (+26.4 %) was increased. In contrast, the MA of all left muscles was increased (range from 2.8 % to 32.1 %). Discussion The results of PDKS indicate that BF was effective in the neck and forearm muscles. Conversely, BF led to more work in the deltoid and triceps. It was assumed that the subjects concentrated on decreasing MA in the forearm muscles rather than in the shoulder and upper arm muscles. We could not clearly elucidate the differences in the AKS results between the right and left. The left keys are heavier than the right ones. It is possible that this had an effect on MA after keystrokes.

ACUTE EFFECTS OF CONTEXTUAL INTERFERENCE, GRADUAL DIFFERENTIAL, CHAOTIC DIFFERENTIAL, AND REPETITIVE BADMINTON SERVE TRAINING ON EEG BRAIN ACTIVITY

HENZ, D., SCHÖLLHORN, W.I.

University of Mainz

Introduction Several studies have demonstrated increased learning rates in variable over repetitive practice. More specifically, this has been demonstrated for the contextual interference (CI) approach (e.g. Brady, 2008) and the differential learning (DL) approach (e.g. Schöllhorn, Hegen, & Davids, 2012) which are representatives of variable practice. To date, little is known on the post-training effects on brain activity comparing CI and DL that possibly contribute to the beneficial effect of variable over repetitive practice. In the present study, we compared post-training effects of repetitive training, CI, gradual DL and chaotic DL on EEG brain activation patterns. Methods Twenty-two semi-professional badminton players performed repetitive, CI, and two DL (gradual, chaotic) badminton serves in a randomized within-subjects design. Electroencephalographic activity was recorded from nineteen electrodes according to the 10-20 system before, and immediately after each 20-minute exercise. Results Analyses of variance revealed a significant effect for training for the theta, $F(4,84) = 2.98$, $p < .02$, $\eta^2 = .17$, alpha, $F(4,84) = 3.06$, $p < .02$, $\eta^2 = .19$, beta, $F(4,84) = 2.78$, $p < .04$, $\eta^2 = .06$, and gamma band, $F(4,84) = 3.07$, $p < .02$, $\eta^2 = .21$. Post-hoc tests revealed increased theta activity in contralateral occipito-parietal regions in gradual DL and chaotic DL compared to CI, $p < .02$, and repetitive training, $p < .02$, with increased alpha activity compared to CI, $p < .02$, and repetitive train-

ing, $p < .03$. After CI training, beta and gamma activity was increased in anterior areas compared to the remaining conditions, $p < .05$ each. Occipital alpha activity was increased in repetitive training compared to the remaining conditions, $p < .05$ each. Discussion Results indicate different underlying neuronal processes in repetitive training, CI, and DL with a higher involvement of central and parietal areas in gradual DL and chaotic DL, anterior areas in CI, and occipital areas in repetitive training. Our results suggest that DL stimulates the somatosensory system more extensively, whereas CI activates specifically executive controlled processing in anterior brain areas. Repetitive training seems to rely on a rather visually guided processing. Comparing the different variable practice schedules of CI and DL, results show that the variable training schedule per se (CI, DL), not the degree of structure causes the difference in EEG brain activation patterns. THE PHENOMENOLOGICAL STUDY OF DIFFERENCES ABOUT A MOVEMENT UNDERSTANDING BETWEEN LEARNER AND LEADER

MAKOTO, S.

National Institute of Technology, Numazu College

In motor learning, it is important that how does the leader understand a target movement. In this understanding, it is clear that the target movement is performing in front of the leader. However, leaders must pay attention to the movement, which shows a phenomenon of the historical one-time. In other words, leader should consider the target movement not as a movement of each case, but as a way of the movement (*Bewegungsweisel*) in the sense of Strauss. This way of the movement has the anti-logic characteristic such as differentiation and identification. And we understand this way of the movement based on sense to guarantee this identity in the form of 'as ~'. For this reason, in order to understand a way of the movement of learners, we must be the subject of discussion consciousness experience with a focus on Kinaesthesia (in the sense of Husserl) of learners. In addition, communication between leaders and learners will play a very important role as a way for understanding this consciousness experience. In order to be corresponded with this communication between leader und learner, they must be dialogue towards the same target. However, the match of this communication target is not an easy work. Therefore, this study, as a first step to identify communication target, leaders understanding structure based on the movement observation and learners self-understanding structure based on an execution of the movement are clarified by using empirical illustration. Through that result, furthermore this study intends to define the target for communication in motor learning. Understanding of the leaders accumulates as some of the failure type through the experience of findings of various failures. In addition, the more abundant teaching experience of leader is, the more this failure example is symbolized. Moreover, this symbol is not an outside shape, but this will differentiate further into multiple sensory images. This process is not due to only an empirical knowledge increased by a simple observation and then it will differentiate through communication with a variety of learners. On the other hand, in understanding of the learner, sensuous difference occurs first through the repeated practice. In addition, learners continue to explore the sense to bring a success of the movement from various differentiated sensory image. Through this explore, learners finally identify the feeling that matches a success of the movement. Finally, it was clarified that an understanding of the learner and the leader is progressing exactly in the opposite direction. However, what is common to both relates to sensory images. By close-up this image, leaders and learners could be corresponded a communication on the same target.

POSTURAL CONTROL IN CHILDREN FROM 6-12 YEARS OLD

GARCÍA-MASSÓ, X., IZQUIERDO, R., VILLARRASA-SAPIÑA, I., GONZALEZ, L.M.

University of Valencia

INTRODUCTION One of the most important function of postural control is to maintain the equilibrium during quiet stance and movement. The development of this postural control during the childhood and adolescence has not been well determined and more studies about this topic are necessary (Cuisinier et al., 2011). The objective of this study was to establish differences in postural control in children of different ages. METHODS A cross-sectional study was carried out in which 208 children participated. The subjects were divided in 6 groups of age: 6, 7, 8, 9, 10 and 11 years old. The sample size of each group was between 22 and 39 subject of both sex. All subjects performed two bipedal trials under two different randomized conditions: i. eyes open and ii., eyes closed. The subjects were instructed in order to maintain the same posture during the four trials. Each trial had a duration of 30 seconds and the subjects were instructed to stand as still as possible. Centre of pressures displacement was acquired using a Wii Balance Board (Wikstrom, 2012) with a sample frequency of 50 Hz. After data acquisition, the signals were digitally processed to obtain the mean velocity in antero-posterior and medio-lateral directions (MVAP and MVML respectively) and ellipse area (EA). Due to normality distribution were not meet, Kruskal-Wallis test was performed to determine the effect of age in the postural control variables. Pairwise comparisons with Bonferroni correction were requested when significant effects were found. The level of significance was set at $p = 0.05$. RESULTS There was an effect of age in MVAP with eyes open ($H_5 = 29.46$; $p < 0.001$), with eyes closed ($H_5 = 11.65$; $p = 0.04$), and MVML with eyes open ($H_5 = 16.55$; $p = 0.005$) and eyes closed ($H_5 = 13.71$; $p = 0.02$). Children of 6 years old showed a higher MVAP than children of 9, 10 and 11 years ($p < 0.05$) in eyes open condition. Moreover, the group of 7 years showed higher MVAP than those of 10 years old ($p < 0.05$). On the other hand, children of 6 years showed a higher MVML than children of 8, 9 and 10 years old in eyes open condition. Regarding eyes closed condition, MVML was lower in children of 8 years than in children of 6. There were not differences in EA variable. DISCUSSION It is important to point out that postural control improves from 6 to 9-10 years old, but there is an involution between 10 and 11 years old. This fact could be due to a higher increase of height or weight of the subjects (Hue et al., 2007). In conclusion, when children growing up, their postural control improve but not their postural stability. Moreover, this trend was found only during eyes open condition. INFLUENCE OF ASCENDING OR DESCENDING FORCE OUTPUT ON THE ACCURACY TO THE TARGET FORCE

HAYAMI, T.I., HIRONO, J.I., KIZUKA, T.2

1: Shinshu University (Nagano, Japan), 2: University of Tsukuba (Ibaraki, Japan)

Introduction In the motor learning or physical training, the accuracy of force modulation is an important factor because it produces the early efficiency. During the force modulation, we select several strategies of force output in order to match the target force. The strategies

involve ascending or descending force output. The previous studies reported the differences that the excitability of primary motor cortex and the threshold of motor unit recruitment between ascending and descending the force output. Therefore, it is considered that these mechanisms have relationships to the difficulty of force modulation. The purpose of this study was to investigate the influence of those strategies on the accuracy to the target force. Methods Twelve subjects were participated in the experiment. Experiment was conducted in accordance with the Declaration of Helsinki. First of all, maximum voluntary contraction (max) of palmar/dorsiflexion force was evaluated in each subject. At the beginning of the experiment, subjects reach their wrist muscle strength to the initial force themselves by means of visual feedback. Then, they were instructed to ascend/descend their force to match the target force (ascend force /descend force: AF/DF) with blind. Finally, the values that they perceived to reach the target force were recorded. The target forces were set 3 levels (30%, 50%, 70%MVC). The initial forces were set to the 15% less than the target force in the AF task, and 15% more than the target force in the DF task. The Constant Error (CE) was calculated as indices the errors between the target force and the actual force. Two-way ANOVA by means of force modulation factor and target force was conducted in each muscle contraction. Post hoc comparisons were made using Bonferroni; the threshold for statistical significance was set at $p < 0.05$. Results In the target force was 30%MVC, the CE of AF condition showed significant higher than DF condition ($p < 0.05$). On the other hand, the CE of AF condition showed significant lower than DF condition in the 70%MVC ($p < 0.05$). There was no significant difference between AF and DF in the 50%MVC ($p > 0.05$). Discussion CE of 50%MVC showed less error in both condition. It was similar to the previous study that force sense was most precise during force reproduction. CE of 30%MVC suggested that the ascending force output was more difficult than the descending force output in low intensity force modulation. CE of 70%MVC suggested that the descending force output was more difficult than the ascending force output in high intensity force modulation. Contact: hayamit@shinshu-u.ac.jp

COMPARISON OF MOTOR SKILL LEVELS BETWEEN EXPERTS AND NON-EXPERTS ACCORDING TO THE EFFECT OF INTERNAL TIMING TRAINING WITH NON-INVASIVE BRAIN STIMULATION ON THE EXTERNAL TIMING TASK

SEO, H.J., KIM, S.J.

Seoul National University

Introduction Neurological studies suggest that timing in motor learning is affected differently according to the types(anode, cathode, sham) of tDCS on the brain and this type of simulation effects individuals differently based on the level of their motor skills. Therefore, the purpose of this study is to investigate and compare the motor skill levels between expert and non-experts according to the effect of internal timing training with non-invasive brain stimulation(tDCS) on the external timing task. Methods The following experiment examined fourteen university students (14 male; age range 20-30, mean = 24, $sd = 4.5$) and fourteen baseball players (14 male; age range 20-25, mean = 21, $sd = 4$). All participants had no history of neurological disease and were right-handed as verified by the modified Edinburgh Handedness Scale(Oldfield, 1971). The twenty-eight participants were divided into four groups of seven persons each which included; expert (Anodal), expert (Sham), non-expert (Cathodal), non-expert (DSham). Group A and C received 15 minutes of tDCS over the cerebellum while participants trained internal timing task. Group B and D received 5 seconds of tDCS on the same area but the tDCS was then switched off without the participants knowledge. The experiment took place over a period of three days. On the first day of the experiment, all participants were tested their external timing task and 2 weeks later, they were tested on their internal timing training with the tDCS applied for two sessions during that day. At the end of the second day, participants were tested their external timing task again to compare the reaction time to results before and after the treatment. Based on the data from these measurements, the independent variable is accuracy and the variable of external timing task, as well as the accuracy of the internal timing task. Results The results of this study were drawn as follows, the type of tDCS(anode, sham) between expert and non-expert had different effectiveness according to the level of motor skills, but not the type of tDCS applied(anode vs sham). Depending on the groups(expert, non-expert) motor skill levels were shown significant improvement of the accuracy and variable in internal timing with tDCS(anode) and its non-expert had bigger improvements than expert in external timing task ($p=0.023$). In addition, accuracy of internal timing training. Discussion Although anodal tDCS has impact on external timing, the impact is no significant. While in an internal timing training, the experts with more stability tended to be less variable in performance whereas non-experts had a significantly difference on their performance. These results show that the timing training is more effective on non-experts compare to the experts. References Oldfield R.C. (1971). BRAIN INFORMATION PROCESSING OF FOOTBALL PLAYERS DURING DECISION MAKING

MATSUTAKE, T.1, NATSUHARA, T.2, TABEI, Y.3, NAKAYAMA, M.3, ASAI, T.3

1.University of Tsukuba, 2.Tokyo Seitoku University,3.University of Tsukuba

Introduction In soccer, there are many situations in which decision making for instantaneous judgments is required. The main research method in this area has been measuring the Reaction Time (RT) and visual search behavior (Ando et al., 2001; Montes-Mico et al., 2000). It has been argued that RT is an elapsed time from the perceived stimulus to the action, and visual search behavior involves cognitive behavior. For that reason, only analyzing these two indicators, will not produce adequate considerations for how soccer players process information during decision making. The purpose of this study, therefore, was to clarify the differences in information processing process of football players with different performance level Methods Participant were college football players who were winners of the all Japan university top level ($n = 5$; Expert) and 5 graduate students with no football experience ($n = 5$; Novices). They used a decision making task (Soccer version). Electroencephalography (0.5–100 Hz) was recorded with Ag/AgCl electrodes from 5 scalp locations: Fz, Cz, Pz, C3, C4. Trials with eye blinks, eye movements and response errors were excluded from analysis (± 80 mV).EMG-RT is the time from stimulus onset to the appearance of the electromyogram (EMG). EMG-RT is a valid indicator of programming time. the electrode is mounted the surface of the gastrocnemius lateral head. Results P300 was identified at the latency and from the polarity to induced latent, latency and amplitude were also measured. In all of the participants of the experiments and the tasks, P300 has been confirmed. EMG-RT has appeared before the P300 latency in all participants. Expert had a significantly shorter RT and EMG-RT than Novices in the task. Discussion The result of this study identified the trend that EMG-RT has appeared before the P300. The human brain always predicts the future and it changes the behavior by calculating the consistency of the results. Rather than to predict and evaluate by a command from the brain, it can be evaluated from the receiving sensation (Seth, A. K. , 2013). This is called the interoceptive inference, and it has attracted attentions in recent years. The results of this study, did not agree with the results of previous studies on the ERP and EMG. For that reason, it can be considered that it is likely to be associated with the interoceptive inference. In future studies, number of participants need to be increased for more reinforced considerations. References Ando, S. , Kida, N. , and Oda, S. (2001) Perceptual and Motor Skills, 92, 786-794. tion, 71(12), 775-780. Seth, A. K. (2013). Trends in cognitive sciences, 17(11), 565-573. Williams, A. M (2000) Journal of Sports Sciences, 18, 737-750.

DEFENDER'S PURSUIT STRATEGY AGAINST AN ATTACKER IN INTERPERSONAL COMPETITION TASK

KAZUSHI, T., MASAHIRO, S., KAZUTOSHI, K.

the university of tokyo

Introduction In ball sports, such as basketball or Association football, a defender should approach an attacker to constraint his/her action. Previous studies were to focus on the lateral position or velocity of the player (Brault et al., 2012; Fujii et al., 2014). In lateral direction, a defender is required to react and follow an attacker (i.e. lead-lag phase relation (Duarte et al., 2012)), suggesting that defender have no choices of pursuit strategies, so the expertise of defender's movement could be hidden in the front and rear direction. Therefore, the aim of this study was to examine defender's movement of the front and rear direction on performance outcomes of 1-on-1 penetrating task. Methods Six amateur football players (mean age 18.6 ± 0.5 years; training experience: 10.8 ± 2.8 years), and six novices (mean age 23.5 ± 1.2 years) took part in the experiment. Paired participants performed a 1-on-1 duel task in an 11x11m outdoor court, playing a role of either attacker or defender. The attacker was asked to cross the end line behind the defender without being caught by the defender. The defender was told to catch the attacker by touching the attacker with both hands. Participants' movement were recorded by two digital video cameras and their head positions were calculated by 3D direct linear transformation method. Mean and SD of peak velocities of the front (negative values) and rear (positive values) direction were then used to quantify the defender's movement over trials. Results No differences in mean of defender's movement were identified between successful outcomes of attackers (18 trials) and defenders (42 trials) (mean±SD = -0.11±0.85 m/s and -0.13±0.65 m/s, p > 0.05). However, variabilities of defender's movement in attackers succeeded were higher than defender's success (0.81±0.30 m/s and 0.60±0.24 m/s, p < 0.01). Discussion The purpose of this study was to investigate the influence of pursuit strategies on the performance outcomes of interpersonal competition task. This study revealed that smaller variability of defender's movement in front and rear direction was related to defender's success, indicating that different defending strategy influence the final outcome of play. Our results suggest that successful defense was achieved through not sink-or-swim but steady and gradual pursuit strategy. References Brault, S., B. Bideau, R. Kulpa, and C. M. Craig (2012). EFFECTS OF BLUE LIGHT TREATMENT ON AGILITY IN BADMINTON PLAYERS

KIM, C., CHOI, J., JI, J.

Soonchunhyang University, Soonchunhyang University, Philips

Blue light has been shown to be comparatively effective to regulation of the human circadian clock contrast to bright light (~10,000lux). Therefore, it is possible for blue light to be effective to physical function of badminton players who work out indoor. The purpose of this study is to exam the effects of blue light treatment on physical performance, especially agility, of highly skilled badminton players. Thirty-seven international badminton players were tested on three separate occasions with the crossover counterbalanced design. In session 1, they tested agility test without any treatment as adaption of the agility test. Session 2 served as placebo treatment by low white light (~200lux) for 30min and session 3 served as blue light treatment by lighting blue light (HF3431) to players for 30 minutes before agility test. As results, placebo treatment (~200lux low white light) improved agility time significantly [46.8(3.3) vs. 43.0(3.3), p<.05]. However, Blue light treatment showed more improvement significantly than low light treatment (placebo treatment) [43.0(3.3) vs. 42.1(3.1), p<0.5]. These findings indicated that blue light treatment can improve physical performance for elite athletic players who have risks for lack of sunlight.

TEMPORAL AND SPATIAL OCCLUSION OF ADVANCED VISUAL INFORMATION CONSTRAIN COORDINATION TENDENCIES IN ONE-HANDED CATCHING BEHAVIOURS

STONE, J.A.1, MAYNARD, I.W.1, NORTH, J.S.2, PANCHUK, D.3, DAVIDS, K.1

1: Sheffield Hallam University (UK), 2: St. Mary's University, Twickenham (UK) 3: Australian Institute of Sport

Introduction Dynamic interceptive actions, like catching, are performed under severe spatial and temporal constraints. Here, we used novel, integrated technology in a spatial and temporal occlusion design, which provided insights on participant behavioural regulation when pre-release visual information of an actor's throwing action was manipulated. Methods An integrated video and ball projection machine was used to create four temporal occlusion and five spatial occlusion conditions of an actor throwing a ball towards participants standing 7m away. Hand kinematics and gaze behaviours of 12 participants were recorded while attempting to catch a projected ball at 13.9 m/s that was synchronised with the video footage showing advanced kinematic information from the actor. Results Analyses of the temporal occlusion manipulations revealed that when footage was occluded at earlier time points, catching performance decreased. Movement onset of the catching hand and initiation of visual tracking on the ball emerged earlier when footage of the thrower was occluded closer to ball release. The spatial occlusion manipulation did not affect catching success, although movement onset emerged later when a greater proportion of the actor was occluded. Later movement onset in both temporal and spatial occlusion conditions was countered by greater maximum velocity of the catching hand when moving it into a catching position. The final stages of the action (e.g., grasping) remained unchanged across both spatial and temporal conditions, highlighting their sensitivity and suggesting that the later phases of the action were organised using ball flight information. Discussion Findings revealed how catching behaviours were continuously reorganised and adapted as information became available in task performance, first by using kinematic information from images of a thrower's actions, and then with ball flight information. Results highlighted the importance of maintaining information-movement coupling during performance of interceptive actions, with these behavioural adaptations having important implications for research that assesses interceptive skills based solely on pre-ball flight information, as in many studies using current video-based simulation paradigms. Neuromuscular Physiology

INFLUENCE OF ELECTROMAGNETIC STIMULATION ON MUSCLE STRENGTH

GORODNICHÉV, R., SHLYAKHTOV, V.

Velikiye Luki State Academy of Physical Education and Sports

INTRODUCTION The purpose - development and testing of muscle strength building strategy by means of magnetic stimulation of muscles against the background of their voluntary contractions. **METHODS** 18 participants, male athletes, aged 19-28, were teamed up into a control (CG) and experimental (EG) groups. All the subjects performed planter foot flexion with an 80% effort of the maximal rotary momentum (MRM) during 15 trainings on the «Biodex» complex. Each training included 10 five-second contractions with a 50-second break in between. During muscle contractions 5Hz - magnetic stimulation, 50% of «Magstim Rapid-2» stimulator maximal power, was applied to the EG subjects' muscle gastrocnemius. Prior, in 5 and 15 days of the training both MRM and EMG of shin muscles were simultaneously registered. The same days H-reflex and M-response of gastrocnemius and muscle soleus were registered as well. **RESULTS AND DISCUSSION** As a result of 15 trainings, MRM increased in both groups – higher in the EG than in the CG by 15,4% after 5 trainings and by 19,4% after 15 trainings. The analyses of EMG parameters, H- and M-responses prove the more significant gain of power potential in the EG to have been achieved by increase of a descending nerve drive to the spinal motoneurons and increase of gastrocnemius motor-neuron pool reflex excitability. **CONCLUSION** Magnetic stimulation of muscles, against the background of their voluntary contraction, can be used as an extra method of muscle strength building strategy. ADAPTIVE CHANGES OF MOTONEURON PROPERTIES IN RESPONSE TO STRENGTH TRAINING

KRUTKI, P.1, MRÓWCZYŃSKI, W.1, ŁOCHYŃSKI, D.2, CELICHOWSKI, J.1

Poznań University of Physical Education

Introduction Different forms of an increased or a decreased muscular activity induce adaptations in electrophysiological properties of motoneurons (MNs). Long-lasting strength training, with repeated short-term and high-intensity exercises, is responsible for an increase of muscle mass and force, however particular types of motor units respond differently to this kind of training. The aim of this study was to determine whether the strength training induces adaptations in electrophysiological properties of motoneurons innervating the trained muscles. **Methods** The study was performed on adult Wistar rats, randomly assigned to the training or the control groups. Animals from the training group were nutritionally conditioned in order to make weightlifting put on their shoulders, in a special apparatus, with progressively increasing load, for 5 weeks. Intracellular recordings from spinal MNs were made in deeply anaesthetized rats from both groups. Passive and threshold membrane properties were measured, and rhythmic firing of MNs was analyzed. **Results** It was demonstrated that 5-week strength training evoked adaptive changes in motoneurons of both fast and slow types. A shortening of the rise time of action potentials, an increase of input resistance, an increase of the maximum frequencies of rhythmic firing, and an increase in the slope of the frequency-current relationship were observed. Moreover, an increase in the input resistance and a decrease in the minimum currents required to evoke rhythmic firing were noticed in fast-type motoneurons only. **Discussion** Effects of the 5-week strength training were: 1) higher excitability of fast-type motoneurons, 2) higher susceptibility of either fast or slow-type motoneurons to an increased or decreased intensity of stimulation. Higher maximum firing rates of MNs as well as higher discharge frequencies evoked at the same level of membrane depolarization imply higher levels of tetanic forces of motor units after the strength training. Modifications of a motoneuronal firing rate by small changes in intensity of depolarization current (i.e., strength of synaptic input) appear to be more effective in MNs after the strength training. PLASTICITY OF MOTOR UNITS CONTRACTILE PROPERTIES WITHIN 8 WEEKS OF THE ENDURANCE TRAINING ON A TREADMILL IN RAT HINDLIMB MUSCLE

CELICHOWSKI, J.1, KRYŚCIAK, K.1, KRYŚCIAK, J.1, ŁOCHYŃSKI, D.1, KACZMAREK, D.1, DRZYMAŁA-CELICHOWSKA, H.1, KRUTKI, P.1, MAJERCZAK, J.2, ŻOŁĄDŹ, J.2

1: Poznań University of Physical Education, Poznań, Poland, 2: University School of Physical Education, Krakow, Poland

INTRODUCTION Several tested forms of changed activity, as spinal cord injury, muscle overload, vibration or locomotor training evoke changes of motor unit (MU) properties, including transformation of their physiological types. The study investigated unknown changes in the contractile properties of the three types of MUs in the medial gastrocnemius (MG) muscle of rat resulting from the treadmill endurance exercise. **METHODS** Rats were assigned to 4 groups, untrained – control (C) and trained, 5 days weekly either for 2 weeks (2W), 4 weeks (4W) or 8 weeks (8W). The intensity of locomotion progressively increased. Finally, rats of the 2W group covered average distance of 5.5 km, 4W - 21 km, 8W - 56 km. Subsequently, functionally isolated MUs were investigated in MG in electrophysiological experiments. **RESULTS** The mean body mass of trained rats was lower compared to C group. Proportion of fast fatigable (FF) MUs was lower whereas of fast resistant (FR) higher in all trained groups. Slow MUs proportion increased only in 8W when compared to C group. Changes of contractile properties concerned mainly FR MUs and included: shortening of twitch time parameters, decrease in twitch-to-tetanus ratio, increase in stimulation frequencies at the steep part of the force-frequency relationship. For all trained groups of FR MUs the fatigue resistance increased and MUs considerably increased the ability to potentiate the force of unfused tetani within the fatigue test. For FF MUs of the 2W lower twitch and tetanus forces were noted. **CONCLUSION** An adaptive changes in MU contractile properties in the endurance training appeared early, after 2 weeks of training, evoked physiological transformation within fast MUs and modified mainly properties of FR MUs. TRANSCRIPTOMIC STUDY OF LUMBAR SPINAL CORD AFTER QUADRICEPS ECCENTRIC EXERCISE

LACROSSE, Z., HODY, S., CROISIER, J.L., ROGISTER, B.

University of Liege

Introduction Intense eccentric muscle contractions induce more "Delayed Onset Muscle Soreness" (DOMS) than concentric and/or isometric muscle contractions. We previously showed that eccentric exercise is followed by modifications in muscle fiber typology with a decrease of glycolytic fibers number in a favor of an increase of oxidative fibers (Hody, 2013). The only systematic intervention that provides a muscle protection against DOMS is to do submaximal eccentric contractions with a progressively increased intensity. This protective

mechanism, called the "Repeated Bout Effect" (RBE), is not well understood so far. However, it is likely explained by cellular, mechanical and neural theories (McHugh, 2003). Regarding the hypothesis of a neural theory, the existence of a protective contralateral effect of a unilateral eccentric exercise emphasizes the implication of neural adaptations (Starbuck, 2012). The objective of this study is to better understand which neural signal would be elicited in the lumbar spinal cord after eccentric contractions, and would bring protection through RBE. Methods Male adult mice (C57BL6) were randomly divided into three groups: (1) downhill running with quadriceps eccentrically-biased contractions, (2) uphill running with quadriceps concentrically-biased contractions and (3) untrained control group. Running groups performed an exercise on an inclined treadmill at a velocity of 20cm/s. This latter consisted of running 18 bouts of 5 minutes interspersed with a 2 minutes rest. Lumbar spinal cord was dissected 24h after the running exercise. Total RNA were extracted and analyzed by RNA Seq. Results & Discussion By this approach, we want to identify modifications in gene expressions that would be specifically triggered by eccentric exercise. RNA Seq identified 117 genes over expressed in eccentric group in comparison with concentric and control groups. Two genes obtain high level of expression: PTGDS (1471,35 in eccentric and 749,856 in concentric with a fold change (log2) of -0,97) and APOD (800,224 in eccentric and 463,647 in concentric with a fold change (log2) of -0,79). Other genes were significantly more upregulated like LCN2, PLAUR, MAFF, TNFSF8 but APOD and PTGDS are more interesting to explain the possible mechanisms which influence the muscle fibers typology by modulating motoneuron signaling coming from lumbar spinal cord. CONTRACTILE PROPERTIES OF FAST AND SLOW MOTOR UNITS IN RAT SKELETAL MUSCLE AFTER BETA-ALANINE SUPPLEMENTATION

PAWLAK, M.1, KACZMAREK, D.1,2, ŁOCHYŃSKI, D.3,2, EVERAERT, I.4, DERAVE, W.4, CELICHOWSKI, J.2

1,2,3: University School of Physical Education (Poznań, Poland), 4: Ghent University (Ghent, Belgium)

Introduction The concentration of carnosine, a dipeptide synthesised from beta-alanine and L-histidine, is almost twice as high in fast than in slow human muscle fibres (Harris et al., 1998), suggesting its important role mainly in fast muscle physiology. It was shown that supplementation with beta-alanine increased muscle carnosine concentration and improved performance (Hill et al., 2007, Baguet et al., 2010). However, the role of carnosine and its analogue anserine – histidyl dipeptides (HDPs) in contractile function of various types of muscle fibres *in vivo* is poorly understood. This study determined contractile properties and fatigability of fast and slow motor units (MUs) in rat medial gastrocnemius muscle *in vivo* after 10-week supplementation with beta-alanine. Methods Ten rats were randomly assigned to beta-alanine (supplemented with ~640 mg/kg BW/day beta-alanine) and control (non-supplemented) group. Contractions of 258 medial gastrocnemius MUs were evoked by electrical stimulation of ventral root filaments in deeply anaesthetised animals. Twitch and tetanus force parameters were compared in fast fatigable (FF), fast resistant to fatigue (FR), and slow (S) MUs. The fatigue resistance was tested with a standard 40 Hz fatigue protocol followed by a second fatigue protocol at 40 Hz in fast and 20 Hz in slow MUs. Results In supplemented rats HDPs concentration increased by 25% in red and carnosine by 94% in white portion of medial gastrocnemius muscle in comparison to control rats. Twitch force of FF MUs and maximum tetanic force of FR MUs increased and half-relaxation time was prolonged in slow MUs of supplemented animals. FF MUs fatigued less during first 10 s and FR MUs between 10th and 60th s. In slow MUs forces declined less during first 60 s of 20 Hz test. **Discussion** This study shows that beta-alanine induced muscle carnosine and anserine loading improves twitch force in FF MUs composed of glycolytic type IIB and maximum tetanic force in FR MUs composed of oxidative-glycolytic type IIA fibres. It also improves resistance to fatigue during first 60 s in fast MUs and reduces force decline during repeated low-frequency stimulation in slow MUs composed of oxidative type I fibres. Our data demonstrate an important function of HDPs not only in fast but also in slow MUs. NCN grant 2013/09/B/NZ7/02554. References Baguet A, Bourgois J, Vanhee L, Achter E, Derave W (2010). FASCICLE BEHAVIOR IN RESPONSE TO VARYING LENGTHENING CONTRACTION VELOCITIES

TAKISHITA, W., NAKAMURA, K., NAKAMURA, M., YANO, S., OGISO, K.

Kogakkan University

Introduction The pennate muscle is generally described as a parallelogram model, but the fascicle contracts nonlinearly. The pennation angle (PA) substantially increases as the fascicle approaches the deep aponeurosis under various conditions. Pressure generated by rapid contraction of the synergist muscles may explain this phenomenon observed using an ultrasound probe tightly fixed to the skin. In these cases, fascicle curvature should not be observed during the lengthening contraction. Therefore, this study was designed to clarify whether the pressure of the synergist muscles influences the fascicle behavior of the agonist muscle by analyzing this behavior during lengthening contraction. Methods Nine male subjects performed two passive ankle dorsiflexion movements under relaxed (Relaxed), voluntary (VOL), and electrical (ELEC) conditions. Under the VOL and ELEC conditions, the calf muscle was lengthened while the subjects exerted 20% of the maximal isometric ankle plantarflexion torque at 90 voluntarily and electrically. The ankle joint was rotated from 110 to 70 at four velocities (5/s, 45/s, 95/s, and 110/s) and returned to the initial position at 5/s. Longitudinal sectional images of the gastrocnemius medialis muscle were obtained at 36 Hz. For each ultrasonic image, the following points were digitized: point P where a fascicle arises from the deep aponeurosis; 5 points (F5, F10, F15, F20, and F25) on the fascicle; and 5 points (D5, D10, D15, D20, and D25) on the deep aponeurosis 5, 10, 20, and 25 mm horizontally from P, respectively. The interior angles $\angle F5 P D5$ (PA5), $\angle F10 P D10$, $\angle F15 P D15$, $\angle F20 P D20$, and $\angle F25 P D25$ were calculated as five types of PAs. Results When the velocity of ankle dorsiflexion was slow, the PA decreased in similar patterns during lengthening under each condition. At the highest velocity, PA5 significantly remained greater than the other PAs under the VOL and ELEC conditions, and tended to be smaller under the Relaxed condition. As dorsiflexion velocity increased, P tended to move toward the distal direction under the VOL and ELEC condition to a greater degree than under the Relaxed condition. **Discussion** When dorsiflexion was performed at the highest velocity under VOL and ELEC, P moved in the distal direction, while the PA nearest to the deep aponeurosis remained greater than the other PAs. If pressure caused by contraction of the synergist muscles had influenced this fascicle behavior, it would not be observed during fascicle lengthening because the pressure would also be decreasing. Therefore, greater PAs near the deep aponeurosis during rapid contractions may be caused by factors other than pressure due to the synergist muscles.

BACKGROUND MUSCLE ACTIVITY INFLUENCES FASCICLE BEHAVIOR DURING REPEATED MAXIMUM MUSCLE CONTRACTIONS

YANO, S., TAKISHITA, W., NAKAMURA, M., OGISO, K.

Kogakkan University

Introduction A parallelogram model is generally used to describe the pennate muscle. However, the pennation angle (PA) is larger near the deep aponeurosis during maximum voluntary contraction (MVC) under various conditions and that the behavior of the muscle-tendon complex is influenced by fatigue. Background muscle activity and prediction of the subsequent movement may also affect fascicle behavior. Therefore, this study was designed to examine the effects of background muscle activity, prediction of MVC timing, and fatigue on fascicle behavior during MVC while shortening (SHO), lengthening (LEN), and isometric contractions (ISO) were passively repeated. **Methods** Fifteen male subjects performed 100 isokinetic knee extension-flexion movements (90/s) with 50 performed at MVC cued by a light at 60° knee angle. MVC was repeated during passively SHO and LEN in every second trial (C1), while the 50 MVC trials were randomly interspersed (C2). Only in the C1 trials were subjects informed beforehand of the light cue timing. MVC was repeated 50 times also during ISO at 60° knee angle every 4 s (C1) or at 5 random times per 20 s (C2). Longitudinal sectional images of the vastus lateralis muscle were recorded at 36 Hz. On each ultrasound image, the following were digitized: point P, where a fascicle arises from the deep aponeurosis; three points (F5, F10, and F15) on the fascicle; and three points (D5, D10, and D15) on the deep aponeurosis 5, 10, and 15 mm horizontally from P. The interior angles $\angle F5 P D5$ (PA5), $\angle F10 P D10$, and $\angle F15 P D15$ were calculated as three types of PAs. Results Increases in PAs (ΔPA) decreased significantly with MVC repetitions while increases in P movement distance (ΔP) remained unchanged in every contraction type. ΔP at MVC during CON were significantly larger in C1 trials than in C2 trials. On the other hand, there were no significant differences between them during ISO. PA5 increased to a significantly greater extent compared with the other PAs at MVC during ISO and ECC. ΔPA and ΔP were significantly smaller in ECC than in the other contraction types. MVC torque was largest in ECC and smallest in CON. C1 trials produced MVC torque larger than that in C2 trials during ECC and CON. **Discussion** Unlike CON, ISO showed no significant differences in fascicle behavior between the C1 and C2 trials. Similar results were observed for MVC torque, suggesting that ISO is a better condition than CON for performing MVC. ECC and ISO significantly increased PA near the deep aponeurosis and produced larger MVC torque. This indicates that larger PA near the deep aponeurosis may contribute to large force production. However, large differences in MVC torque between the C1 and C2 trials during ECC show the high difficulty of performing MVC during ECC.

TENSIOMYOGRAPHY OF SELECTED LOWER LIMB MUSCLES IN SPRINTERS AND LONG DISTANCE RUNNERS.

HIRATSUKA, K.

Kokushikan University

Introduction It is well known that sprinter has exceeded fast twitch fibers. Thus, the contraction velocity of lower limb muscles shorter than long distance runners. However, mechanical properties of the belly in selected lower limb muscles are not clear by TMG method. Therefore, the aim of this study was to clarify the mechanical properties of thigh and leg muscles in sprinters and long distance runners. **Methods** Fifty-five male collegiate athletes from sprinters (SP; n=27; mean \pm SD age, height and weight were 20.1 ± 1.5 years; 172.7 ± 3.8 cm and 64.2 ± 4.0 kg) and long distance runners (LDR; n=28; mean \pm SD age, height and weight were 19.5 ± 1.0 years; 170.9 ± 5.7 cm and 55.7 ± 4.2 kg). The mechanical properties of rectus femoris (RF), vastus medialis (VM), vastus lateralis (VL) and biceps femoris (BF) in thigh, and tibialis anterior (TA), gastrocnemius medialis (GM) and gastrocnemius lateralis (GL) in leg were assessed by TMG method. Mechanical properties of delay time (Td), contraction time (Tc) and maximal displacement of the muscle belly (Dm) were analyzed in both groups. Results Td and Tc of RF (Td: 23.4 ± 0.5 ms, Tc: 25.2 ± 0.9 ms) were showed in among the muscle groups in SP. Tc of BF (37.8 ± 1.6 ms) in LDR was observed long contraction time. Whereas, Td for RF (23.4 ± 0.5 ms) and BF (21.3 ± 0.4 ms) in SP were significant shorter reaction times than LDR. Tc of BF (25.2 ± 0.9 ms) in SP was significantly shorter contraction time than that of LDR (27.8 ± 0.8 ms). And also, same tendency were observed for RF (21.1 ± 0.8 ms), VL (22.1 ± 0.5 ms) and GL (23.1 ± 1.1 ms). Dm of BF in SP showed significant lower values than LDR. **Discussion** In this study, contraction times for rectus femoris, vastus lateralis, biceps femoris and gastrocnemius lateralis in sprinter were significantly differed to the long distance runners. Furthermore, mechanical properties of delay time, contraction time and maximal displacement of biceps femoris were extremely differed between sprinter and long distance runners. From these results, it was considered that mechanical properties on thigh and leg muscles measured by TMG method may reflect to the muscle fiber composition. A STUDY TO EVALUATE THE EFFECTS OF A NEUROMUSCULAR INJURY PREVENTION PROGRAMME IN ADOLESCENT MALES PARTICIPATING IN HURLING

LODGE, C., KELLY, S.

Institute of Technology Carlow

INTRODUCTION: Adolescents involvement in organised sport has never been more popular with nearly 90% of post primary school students in Ireland participating in sport, however, this increased level of activity has reportedly caused concern regarding the potential risk and severity of sporting injuries (2). Previous research into adolescent injury incidence in a variety of multidirectional field sports, including rugby, soccer, and basketball have established a decline in injury rates following the implementation of injury prevention programmes (1). Former investigations into injury incidences and rates within the Gaelic Athletic Association (GAA) has primarily focused on elite adult players, with a lack of data on the adolescent cohort. Adolescents are at risk in terms of overload and growth related injuries in sport, and the GAA is no exception to this (3). **METHODOLOGY:** Over 800 male subjects aged 13 – 18.5 years were recruited from fourteen post primary schools, seven schools participated in the intervention group and seven in the control group. The intervention group implemented an injury prevention programme namely the GAA 15 before training and matches. The control group adopted their normal warm-up behaviour prior to matches and training. At the commencement of the experimental phase each player underwent a screening process to assess their baseline record of their neuromuscular function and physical performance measures. These performance tests consisted of a 20 meter sprint, counter movement jump and the y-balance assessment. The assessments were then repeated when the players exited their competitive season, but no less than six weeks from commencement. Player wellness, activity exposure and injury incidence will be recorded daily by a players mobile phone web application. **RESULTS:** Preliminary results are expected in May 2016 and available for conference presentation. It is hypothesised that the use of an injury prevention programme will have a positive effect on non-contact lower limb injury incidence along with neuromuscular performance elements. **DISCUSSION:** It is predicted that the results of this investiga-

tion will show that the implementation of an neuromuscular injury prevention programme can reduce non-contact sporting injuries in adolescent males participating in GAA field sport. The findings of this research will help to contribute to a knowledge base regarding injury prevention strategies in adolescent males participating in sport. REFERENCES: 1. A STUDY TO INVESTIGATE THE EPIDEMIOLOGY AND MODIFIABLE RISK FACTORS FOR INJURY IN ADOLESCENT GAELIC FOOTBALL

MLEY, P.

Institute of Technology, Carlow

Aim: To determine the influence of various modifiable risk factors on injury risk in adolescent Gaelic football players. **Introduction:** The 2014 Annual report by the GAA claims there are 6,969 Gaelic football players between the age of 13 and 17 in talent academies. Recent research suggests that 32% of adolescent Gaelic football players will suffer an injury in a given year; equating to over 2,200 injuries to talent identified youths alone(1). O'Connor (2015) also found that 64% of the injuries were non-contact in nature and may be preventable. There are a number of factors related to an increased risk of injury in this cohort such as overtraining, poor balance and strength(2) and lack of sleep(3). However, to-date, no research has been carried out to quantify the influence of these risk factors on adolescent injury rates in Ireland. The objective of the present study is to establish the potential factors for increased risk of injury and, in-turn, identify potential strategies to decrease injury risk. **Methodology:** 498 male Gaelic football players aged between 13 and 18 years were recruited from 14 post-primary (second level) schools across Leinster. All subjects completed a daily questionnaire via the smartabase smartphone/tablet application. The questionnaire obtained information on daily training loads (RPE x Duration), sleep quantity (Hours) and self reported injuries. Subjects were tested for performance of strength, power, balance and flexibility at the beginning and end of the trial period. Qualitative analysis will also be carried out via semi-structured interviews. These will be done with one coach and one player from each team towards the end of the study to gain a practical insight into this method of athlete monitoring. **Results:** Preliminary results for this study are expected in May 2016 and will be reported at the conference. It is expected that the project will identify risk factors or groups of risk factors which have the greatest impact on injury rates. A regression analysis will be utilised to determine the influence of each risk factor injury. The qualitative analysis will provide an insight into the practicalities of implementing self-monitoring for adolescent athletes. **Discussion:** This study will contribute to a growing body of literature regarding injuries and injury prevention among adolescent athletes. It is the first study of its kind to be carried out in Ireland and also the first study executed with the intent of establishing the influence of individual risk factors or groups of risk factors on injury incidence in this cohort. **References:** 1. Introduction Labeled amino acid infusion trials have been used in the literature to measure myofibrillar muscle protein synthesis (MPS). For instance, it is known that MPS can be elevated for at least 24-48h after resistance-training (RT) and this pattern can vary depending on RT status (i.e., trained and untrained). However, several aspects of this method could preclude a greater applicability of MPS in aligning with phenotypic outcomes, such as the short durations (hours), cannulation, high cost of sterile infusions, with a high demand of control (lab environment enclosure), restricting normal daily activities and feeding patterns. An interesting method that overcomes most of the issues above is the use of deuterium-oxide (D₂O) ingestion, as it does not require infusions nor does it interfere with daily activities, being ideal to measure MPS in a RT period (Wilkinson et al., 2014). In addition, using an integrative approach to measure MPS allows an 'acute' but longer (days-weeks) precise estimation on the physiological increase in MPS after an RT bout. Therefore, to capture a more integrated scenario of the MPS response throughout a RT period, we assessed day-to-day integrated MPS using D₂O at different training-phases. **Methods** Ten young men (27 ± 3 y; 69.4 ± 8.8 kg; 172 ± 6 cm) performed 10wk RT (45° leg-press and leg extension exercises, 3 sets of 9-12 RM). Day-to-day integrated MPS analysis was conducted at an untrained basal state (Pre) and 24h and 48h after the first RT bout (W0), third week of RT (W3) and last week (W10) of RT by D₂O ingestion (100ml bolus, 72h before first biopsy), muscle biopsies (Pre-, 24h and 48h-post RT bout - 1-24h only at W0) and saliva measurements (from 72h before first biopsy until 48h after the RT bout). **Results** Integrated MPS increased after 24h ($P < 0.001$) and 48h ($P = 0.008$) at W0, but only after 24h at W3 ($P = 0.015$) and at W10 ($P = 0.05$) compared with W1. MPS were greater at W0 compared to W3 and W10 (no difference between W3 and W10) and 24h values were higher than 48h independent of the week of evaluation. **Discussion** Early on RT (W3), the rise in MPS is already down regulated, but is maintained until, at least, at W10 of RT. Independent of training-phase, the increase in MPS in the first 24h after exercise is always greater than 48h. Integrated MPS measured on a day-to-day basis after RT allowed a higher understanding in estimating how MPS is modulated acutely at different training-phases. **References** Wilkinson et al. (2014). CONTRACTILE PROPERTIES OF MOTOR UNITS AFTER 14 DAYS OF HISTIDINE DEPRIVATION IN RATS

KACZMAREK, D.1,2, LOCHYNISKI, D.3,2, PAWLAK, M.1, EVERAERT, I.4, BLANCQUAERT, L.4, DERAVE, W.4, CELICHOWSKI, J.2
1,2,3: University School of Physical Education (Poznan, Poland), 4: Ghent University (Ghent, Belgium)

Introduction The role of carnosine, a dipeptide synthesized from L-histidine and beta-alanine, in skeletal muscle contraction and fatigue resistance is still incompletely understood. We recently found that increased muscle carnosine content by beta-alanine supplementation improved motor unit (MU) contractility. Several studies showed that a histidine-free diet decreases carnosine content in rodents (Tamaki et al., 1977, Clemens et al., 1984, Fuller et al., 1947). However, the effect of histidine deprivation induced carnosine depletion on muscle contractility is unknown. **Methods** Ten 6 month-old male Wistar rats were randomly assigned to experimental (HFD) or control (CON) group fed histidine-free or standard diet for 14 days, respectively. In order to maintain the same level of body mass loss, food intake was controlled and balanced between both groups. In HFD group body mass decreased by 11.7% while in CON group by 10.6%. In electro-

physiological experiments, contractions of MUs in medial gastrocnemius (MG) muscle were evoked by electrical stimulation of ventral root filaments. MUs were classified into fast fatigable (FF), fast resistant (FR) and slow (S). Maximum tetanic force (TetF) and force profile during the two separate fatigue tests were analysed. Results In HFD group, carnosine levels were significantly lower than in CON group in a white and red portion of MG muscle by 26% and 34%, respectively. Histidine deprivation did not result in lower muscle mass or muscle-to-body mass ratio. The TetF did not differ between groups either in fast or slow MUs. During the first fatigue test in FR MUs force was initially higher but from 40 to 120 s it was lower in HFD animals. Unexpectedly, in the second fatigue test the force of FR and S MU was better maintained in HFD than CON rats. Discussion In this study, we confirmed previous findings by Tamaki et al. (1977) and Clemens et al. (1984) that histidine deprivation decreases carnosine content, however, to a much lesser extent. The results indicate that short-term histidine deprivation and the carnosine decrease do not attenuate force of MUs. Based on these preliminary findings, it is possible that in this condition compensatory mechanisms may be involved in the regulation of MU force. Supported by NCN grant 2013/09/B/NZ7/02554. REGIONAL DIFFERENCE IN CEREBRAL OXYHEMOGLOBIN CHANGES DURING CYCLING EXERCISE: A NEAR-INFRARED SPECTROSCOPY STUDY

TSUBAKI, A., TAKEHARA, N., TOKUNAGA, Y., SATO, D., TAMAKI, H., ONISHI, H.

Niigata University of Health and Welfare

During cycling exercise, cerebral oxyhemoglobin (O_2Hb) changes in motor-related area were measured on near-infrared spectroscopy (NIRS) (Tsubaki et al, in press). However, regional differences in O_2Hb within motor-related areas are unknown. The purpose of this study was to investigate the brain cortical activity within motor-related areas and to evaluate the regional difference during multistep incremental cycling exercise. Methods Eighteen healthy volunteers (9 women) participated in this study. After an incremental exercise test on a cycle ergometer to determine the $VO_{2\text{peak}}$, the subjects performed a multistep incremental exercise on a separate day. After a 4-min rest and a 4-min warm-up on the ergometer, exercise began at workloads corresponding to 30%, 50%, and 70% $VO_{2\text{peak}}$, with each stage lasting 5 min, followed by a 4-min cool-down after 70% $VO_{2\text{peak}}$ cycling. O_2Hb from the supplemental motor area (SMA) and sensorimotor cortex (SMC) were measured by using a 34-channel NIRS system. Skin blood flow (SBF) and mean artery pressure (MAP) were measured synchronously during the experiment. The mean O_2Hb in each area, MAP, and SBF were expressed as the change from the mean rest phase value and calculated every 60 s. The peak O_2Hb values were compared according to exercise intensity by using one-way analysis of variance and changes in the values within the same load were compared according to area by using a paired t-test. Results SBF and MAP increased from 30% $VO_{2\text{peak}}$ to the end of exercise, and the peak value was increased by exercise intensity ($F(3,68) = 18.225$, $p < .01$ in SBF; $F(3,68) = 17.490$, $p < .01$ in MAP). The O_2Hb increased from 30% $VO_{2\text{peak}}$ to the early phase of 70% $VO_{2\text{peak}}$. The peak O_2Hb value was increased by the exercise load in each area ($F(3,68) = 6.227$, $p < .01$ in SMA; $F(3,68) = 8.965$, $p < .01$ in SMC). During the latter half of 70% $VO_{2\text{peak}}$, O_2Hb decreased to the end of exercise. The change in SMC was -2.64 ± 2.66 (a.u.), and that in SMA was -1.34 ± 2.38 (a.u.). The decrement value in SMC was larger than that in SMA ($p < .01$). Discussion A O_2Hb decrement was observed in SMC and SMA, and the changes were greater in SMC during 70% $VO_{2\text{peak}}$ exercise. Motor cortex activity elevated the exercise intensity increment (Brümmer et al, 2011). Cortical activation pattern based on O_2Hb differed by brain region (Jung et al, 2015). Our results suggest that SMA and SMC have different activation patterns during high-intensity exercise. References Tsubaki et al, Adv Exp Med Biol in press. EFFECTS OF LOWER LEG COMPRESSION SLEEVES ON LOCOMOTION ECONOMY

KURZ, E., ANDERS, C.

Clinic for Trauma, Hand and Reconstructive Surgery

Introduction Athletes increasingly use compression garments to enhance their physical performance. Previous investigations of lower leg compression sleeves on running mechanics did not reveal any systematic effects (Stickford et al. 2015). However, effects of compression sleeves on electrophysiological characteristics of muscular efficiency during locomotion have not been examined so far. Thus, this study was designed to identify if lower leg compression sleeves are able to systematically alter muscle strain during locomotion. Methods Twenty-two recreationally active men (age: 25 ± 3 years) walked (6 km/h) and ran (12 km/h) on a treadmill for approximately 30 strides to avoid fatiguing effects with (SL) or without (CON) wearing special designed lower leg compression sleeves (Bauerfeind AG). Myoelectric activity of five lower leg muscles (tibialis anterior, TA; fibularis longus, FL; lateral and medial head of gastrocnemius, LG, MG; soleus, SO) was determined bilaterally using Surface EMG. Effects of applying lower leg compression sleeves on walking and running economy were analyzed by comparing the cumulative muscle activity per distance traveled (CMAPD, Carrier et al. 2011) of the CON and SL situations with repeated measures analyses of variance (sleeve[2]xside[2]xmuscle[5]), separately for each velocity. This was followed by Tukey-HSD post hoc tests. Effect sizes were calculated as partial eta squared (η^2). Results Since "side" did not show any main effect, data from both sides were pooled. Subsequent analyses showed significant interaction effects of "sleevexmuscle" for both locomotion types (walking: $F(4, 80) = 4.7$, $P = 0.002$, $\eta^2 = 0.19$; running: $F(4, 84) = 3.1$, $P = 0.02$, $\eta^2 = 0.13$). Independent of the locomotion type, post hoc comparisons revealed significantly ($P < 0.001$) lower CMAPD values in TA (12%), FL (10%), MG (15%) and SO (14%) during walking and systematically reduced CMAPD levels of TA (9%), LG (12%) and SO (13%) during running. Discussion Lower leg compression sleeves reduce ankle muscle effort that has the potential to enhance locomotion performance, most probably caused by systematic alteration of local mechanisms. The actual findings may thus point towards an optimized muscular economy situation while wearing lower leg compression sleeves and the ability to postpone muscle fatigue during endurance locomotion. EVALUATING THE EFFECT OF LYCOPENE ON THE LEVEL OF PLASMA MALONDIALDEHYDE IN ATHLETES BY HIGH PERFORMANCE LIQUID CHROMATOGRAPHY

ZHANG, Q., SUN, M.

Shanghai Research Institute of Sports Science

Introduction Malondialdehyde (MDA), as the final product of lipid peroxidation, was usually detected as the marker of oxidative stress in human body. However, traditional detection methods of MDA, such as UV spectrophotometry and enzyme-linked immunoassay, were lack of specificity and sensitivity. Thus, the purpose of this study was to establish an accurate, rapid and effective method based on high performance liquid chromatography (HPLC) to determine MDA in human plasma. With this method, we quantitatively evaluated the extent of lipid peroxidation in human body and further studied the antioxidant effect of lycopene supplement on athletes. Methods (1) The method of HPLC was established with thiobarbituric acid (TBA) as the derivative reagent and the separation was performed on a Phenomenex Llna C18 column (150 mm×4.6 mm, 5μm). The detection wavelength was set at 532 nm. (2) Fourteen professional female players from Shanghai Women's Field Hokey Team were randomly divided into two groups: the lycopene group ($n = 7$) and the control group ($n = 7$). The experiment was carried out in winter training with high training intensity. During the experiment, the lycopene group was supplied with lycopene capsule (which was equivalent to an intake of lycopene as 28 mg/d) for 30 days and the control group was not treated. All the subjects' MDA level in plasma before and after the experiment was detected with the established HPLC method. Results (1) Under the optimized HPLC conditions, good linearity of MDA was obtained in the range of 1.0-40.0 μmol/L and the correlation coefficient was 0.9998. The recoveries of MDA at the addition of three levels (2.5, 5.0 and 10.0 μmol/L) was in the range of 100.6%-118.6%. (2) The application research of lycopene supplement showed that after heavy-load training for one month, the MDA level of the control group was significantly increased (4.52 ± 0.31 vs. 5.78 ± 0.65 μmol/L, $P < 0.01$), while the lycopene group showed no significant difference (4.81 ± 0.26 vs. 4.91 ± 0.31 μmol/L). Furthermore, after the experiment, the MDA level of the lycopene group was significantly lower contrasted with the control group. Conclusion From this study, we successfully established an accurate and reliable HPLC method with good specificity, which was suitable for the determination of MDA in human plasma. Based on the method, we further found that lycopene supplement could inhibit the increase of MDA level during the period of intensive training, which indicated lycopene does have some antioxidant effect in human body. It might also provide some evidence for the role of lycopene in heavy-load training, such as preventing sports fatigue and injury. References Richard MJ, Guiraud P, Meo J, Favier A. (1992). GASTROINTESTINAL DISORDERS CAUSED BY USING DRY FOOD

PLAVINA, L.

National Defence Academy of Latvia

Introduction Military activities are characterized with high physical load and psychological load. Military personnel are trained in military field exercises several times. The meal in the field exercises support physical endurance and provide physical fitness of military personnel Wang et al,2015; Booth, 2003). According the military legislation all military personnel should be supply by the hot meal, but the cases when that is impossible, participants of the field training are provided by the dry meal with energy capacity 1200 kcal three times in the day. Energy expenses during the daily activities in the field exercises is high, there for food energy capacity is high, about 3500-7200 kcal. In some cases combat feeding can caused health disorders that diminish physical fitness and operational readiness of individual (Cochet et al,2015) Material and Methods We provide questionnaire for participants of the military field exercises that allow estimates quality and quantity of the dry food from the users' point of view. There are 120 respondents both genders: respondents from NAF Infantry instructor school and National Defence Academy. Results Dry meal covers requirements in food energy for 53% of respondents the rest 47 % feel hunger. Only 23 % respondents give positive assessment to the quality of the dry meal, the rest the 73 % of respondents dissatisfied with assortment of the component of the dry meal. Military personnel pass through annual health capacity evaluation procedures. 3 % of respondents have gastrointestinal disorder. The dry meal that is used (during three days of military training) causes negative consequences: 30% of respondents pointed heartburn, and 10% stress attention to the pain in abdomen, but 3% note the vomiting and diarrhoea. Conclusion 1. Dry meal provides basic level of nutrients during the field exercises for individuals – military personnel, but amount of dry food is less the military regulation require; 2. Gastrointestinal problems are not take the leading position in the list of diseases, but for 30% participants of the experimental group had gastrointestinal disorders as heartburn after using dry meal, 10% of respondents had abdominal pain, but 3 % - vomiting and diarrhoea. THE EFFECT OF POMEGRANATE EXTRACT ON OXYGEN TRANSPORT AND EXERCISE PERFORMANCE IN HIGHLY-TRAINED CYCLISTS AT LOW AND HIGH ALTITUDES

CRUM, E., CHE MUHAMED, M., STANNARD, S.

Massey University

Introduction Maximal aerobic exercise performance is often limited by the rate of oxygen (O₂) delivery via the erythrocytes to the muscles for energy production (Wagner, 1996). Nitric oxide (NO), produced endogenously by NO synthases in epithelia and also from dietary nitrate (NO₃-), induces dilation of the arterioles, improving blood flow and reducing erythrocyte damage. Pre-exercise intake of NO₃- rich beetroot juice (BJ), reduces O₂ uptake (VO₂) for the same submaximal cycling workload, leading to an improvement in power output at VO_{2max} and time to exhaustion during a cycling time trial (TT) (Bailey et al. 2009; Lansley et al. 2011; Larsen et al. 2007). However, BJ has little such effect in highly-trained athletes who have greater vascular control. Pomegranate extract (POM) is high in NO₃- and polyphenols; the latter increasing NO production in the stomach and protecting NO from oxidative damage (Ignarro et al. 2006). This study investigated whether POM reduces the O₂ cost of exercise in highly-trained cyclists and if the effect is greater at high altitude where lower atmospheric O₂ pressures impair O₂ delivery to the muscles. Methods Eight cyclists completed three stages of exercise at 50, 65 and 80% of their VO_{2max}, followed by a TT to exhaustion (TTEx) at a workload calculated to elicit VO_{2max}. The protocol was completed four times: at sea-level (SEA) and 1650m of altitude (ALT), with pre-exercise consumption of 1000mg of POM or a placebo (PL) at both altitudes. VO₂ was measured in the last minute of each stage. A repeated measures ANOVA was performed for all dependent variables. Results

Maximal VO₂ during the TT was significantly decreased in SEAPOM compared to SEAPL and increased in ALTPOM compared to ALTPL ($p=0.022$). Submaximal VO₂ values were not affected. TTEX was reduced in ALT ($p=0.01$), but was not influenced by POM. Discussion The improved O₂ transport efficiency following POM allowed a similar TTEX with a lower maximal O₂ cost at SEA, but POM enabled restoration of SEA VO_{2max} values at ALT. Previous research has proposed that NO-induced vasodilation increases blood perfusion and O₂ delivery to distal areas of myocytes, improving the matching of O₂ delivery and requirement (Bailey et al. 2009). In POM, the combination of NO₃⁻ to produce NO and polyphenols to protect it, were effective in limiting the restrictions to O₂ delivery in high altitude conditions. ACUTE ORAL CAPSIANOIDS SUPPLEMENTATION HAS NO BENEFICIAL EFFECT ON RECOVERY FROM EXERCISE-INDUCED FATIGUE IN HUMANS

CHENG, I.S., CHAN, Y.T., LIU, Y.C., HSU, C.Y.

National Taichung University of Education

Introduction Previous studies showed that capsinoids (CNS) are able to enhance energy expenditure, fat oxidation, antioxidant and insulin action in mice and humans (Kawabata et al., 2009; Luo, Peng, & Li, 2011; Snitker et al., 2009). Little study is regarding to whether CNS administration is expected to cause metabolic consequence in turn to affect muscle glycogen conservation following a glycogen depletion cycling exercise and attenuate exercise induced fatigue in humans. Therefore, this study has been proposed to demonstrate the effect of acute oral capsinoids (CNS) supplementation on attenuating exercise induced fatigue and conservation of muscle glycogen exhaustion following a glycogen-depletion cycling exercise. Methods Eleven healthy male subjects (aged 20.5 ± 0.2 years old; height 171.3 ± 2.4 cm; weight 67.0 ± 3.4 kg; BMI 21.5 ± 0.6 ; VO_{2max} 46.4 ± 2.4 ml/kg/min) were participated in this crossover designed study, and considered them as CNS or placebo trials. Participants in respective trials consumed either 30 mg CNS or placebo with light breakfast (300kcal, 60 % carbohydrate, 25 % fat, 15 % protein) before exercise, and then completed a 70-min cycling exercise with glycogen-depletion protocol. Subjects were crossed-over and repeated the study 7 days after washout period. Biopsied muscle samples were obtained from vastus lateralis before and immediately after exercise. Simultaneously, expired gas and blood samples were measured during the study periods for all subjects. Results The results showed that there were no difference responses in muscle glycogen, blood glucose, lactate dehydrogenase and creatine kinase levels between CNS and placebo trials. Plasma NH₃ was lower in CNS compared to placebo immediately and 3-h after exercise. Nevertheless, lower response of circulating NEFA was found in CNS trial compared to placebo. Furthermore, the rate of glycogen depletion in CNS trial was similar to that in placebo before and immediately after exercise. Discussion The results of this study were inconsistent with the evidences in previous animal and human studies (Kawabata et al., 2009; Luo, Peng, & Li, 2011; Snitker et al., 2009). Therefore, the hormesis effect of CNS supplementation on human study will be examined in next study. Findings from blood biomarkers in this study showed no supporting evidence that CNS could attenuate exercise-induced fatigue in young men. Besides acute CNS supplementation is unable to influence metabolic consequences, which in turn affect the conservation of glycogen depletion following glycogen-depletion cycling exercise. EFFECTS OF ALKALINE VERSUS MINERAL WATER ON ENDURANCE PERFORMANCE IN TRAINED CYCLISTS

HOTENROTT, K., KETELHUT, S., RABE, J., ZURLEIT, A.

Martin-Luther-Universität Halle-Wittenberg

Introduction Water provides a performance-limiting factor during exercise. Besides quantity and time of consumption, quality and composition are important. It has been shown that alkaline supplementation (AS) can prevent a decrease in blood HCO₃⁻ during high intensity exercise (Pouzash et al., 2012). Therefore AS with hydrogen carbonate may increase endurance capacity (EC). The aim of the study was to evaluate the influence of natural alkaline glacier water (AGW) and commercially available mineral water (MW) on aerobic and anaerobic EC. Methods The quasi-experimental study involved 7 female and 11 male cyclists (mean age 26.4 ± 4.8 yr, BMI 23.1 ± 2 , 6 kg/m^2) that engaged in 7.2 ± 2.6 hours of physical activity per week. Subjects displayed a mean VO_{2max} of 56.9 ± 7.8 ml min⁻¹ kg⁻¹ in male, and 42.4 ± 2.4 ml min⁻¹ kg⁻¹ in female. Using a controlled, blinded cross-over design subjects were randomized in two groups. Time-to-exhaustion-test (TET) at 80% of individual VO_{2max} and anaerobic 75-s-cycling test (A75) at 90 R/min were conducted with a 20 minute recovery in between. Test protocol was repeated after 7 days. Three days before each test protocol athletes consumed 3 liters of MW or AGW every day. On test days, athletes drank another liter of MW or AGW one hour before and a pint in between the two tests. The diet in the days before was controlled and standardized with respect to the liquid supply. Statistical analysis was performed using SPSS 20.0. The significance level was set to $p \leq 0.05$. Results Cyclists consuming AGW scored a significant ($p < .01$) longer travel time in the TET than cyclists consuming MW (47.4 ± 6.7 min versus 43.4 ± 9.3 ; 8.4%). After the test, oxygen uptake in the intervention with AGW was significantly higher ($p = .027$) than in the intervention with MW ($46.8 \text{ ml min}^{-1}\text{kg}^{-1}$ versus $44.9 \text{ ml min}^{-1}\text{kg}^{-1}$). During A75 subjects drinking AGW achieved a significant higher ($p < .01$, 8.2%) output (446.6 ± 164.9 watts) compared to subjects drinking MW (410.0 ± 128.8 watts). Discussion Milieu shifts are an important limiting factor in endurance performance (Heil, et al., 2012). During intense physical stress the blood pH can fall below 7.0, decreasing the oxygen binding properties. Various buffer systems can influence the pH value (Pilegaard et al., 1999) effecting the acid-base balance. In this context it has been shown, that alkaloids can increase the blood buffer capacity and therefore improve EC (Nielsen et al., 2002). An improved buffering capacity and oxygen-binding capacity through AGW may have contributed to the improved performance in the cycling test, highlighting the performance enhancing effects induced by a natural product from the glaciers. INFLUENCE OF A PALEO-DIET INTERVENTION ON TASTE PERCEPTION IN HEALTHY PEOPLE

BROECKL, F., WOESTMANN, L., KRUSCHE, T., PLATEN, P.

Ruhr-Universität Bochum

Introduction: A balanced and healthy diet is fundamental for a general performance in sports. The Paleolithic diet (PD) is associated with positive health due to its relation to the human genome and the exclusion of processed products. The eating pattern of recreational athletes is largely disturbed and relay to troubles in taste perception [2]. Therefore the aim of this explorative study was to investigate the effect of PD on taste thresholds. The knowledge of bitter taste perception suggests that it will undergo the most significant change under modified circumstances (e.g. altitude) [3]. Methods: Taste thresholds [detection threshold (DT); variation threshold (VT)] of 16 healthy subjects ($m=13$; $w=3$; age= 22.3 ± 3.2 ; BMI= 23 ± 2.1) were investigated before (d-6), during (d2, d5) and after (d+1, d+60) a 10 day PD intervention. Increasing molar concentrations of compounds representing sweet, salty and bitter were presented by using the Three-Drop-Test [1]. Results: Mean DT of bitter and salty decreased absolutely on d2, d5, d+1 and d+60 compared to d-6 [bitter: 4.3 ± 2.0 , 4.1 ± 1.9 , 3.8 ± 1.2 , 3.6 ± 1.6 , 4.1 ± 1.6 ; salty: 4.6 ± 2.0 , 4.6 ± 2.1 , 4.1 ± 1.5 , 3.6 ± 1.0 , 3.8 ± 1.3 , respectively]. Mean DT of sweet decreased absolutely from day d-6 to d2, d5, d+1 and d+60 [3.9 ± 1.3 , 3.3 ± 1.4 , 3.5 ± 1.2 , 3.7 ± 1.4 , 3.4 ± 1.4 , respectively]. Mean VT of bitter increased absolutely from d-6 to d2, d5, d+1 and d+60 [1.8 ± 9.2 , 1.1 ± 1.3 , 2.3 ± 1.4 , 2.3 ± 1.1 , 2.0 ± 1.2 , respectively]. Mean VT of salty decreased absolutely from d-6 to d2, d5, d+1 and d+60 [2.1 ± 9.1 , 1.9 ± 9.1 , 1.9 ± 8.2 , 2.0 ± 8.1 , 1.8 ± 8.8 , respectively]. Mean VT of sweet show considerable fluctuations. It decreased absolutely from d-6 to d5 and d+60 [2.0 ± 1.2 , 1.7 ± 9.1 , 1.8 ± 1.1 , respectively], but it also increased absolutely on d2 and d+1 [2.3 ± 1.3 , 2.1 ± 9.9 , respectively]. Conclusion: The study showed that a 10-day PD application affects the taste thresholds in healthy people. When looking at the DT of all tastes, particularly in long-term cases, the results indicate a tendency of increasing sensitivity. As already suspected an especially continuous shift was seen at the DT of bitter [3]. We speculate that the sensitivity of tastes increase because of the intake of only natural food and the absence of foodstuff additives in processed products. Literature 1. Ahne, G., et al. (2000). DOES A PALEOLITHIC DIET INFLUENCE PERFORMANCE OR METABOLIC PARAMETERS AND IS IT SUITABLE IN EVERYDAY LIFE OF YOUNG SOCCER PLAYERS? – A PILOT STUDY

OERTZEN-HAGEMANN, V., EIBL, A., PLATEN, P.

Ruhr-Universität Bochum

A balanced and healthy diet is essential for elite athletes and thus it is for soccer players. Nevertheless many investigations show that the eating patterns of young soccer players are largely inadequate. To satisfy energy needs and optimize performance a modification seems to be necessary. A paleolithic diet (PD) is assumed to be associated with positive health due to its exclusion of processed food products. The aim of the present study was to investigate whether a PD is compatible for young German soccer players and to evaluate metabolic parameters at rest and during endurance exercise. 17 young soccer players (age: 14.4 ± 0.5 years; body mass: 64.8 ± 6.5 kg; height: 173.5 ± 6.5 cm, fat mass: 10.8 ± 1.2 %) completed two test trials, separated by a 4-week intervention period. The intervention group (PG) ate a paleolithic diet based on the lifestyle conditions more than 10.000 years ago preferring minimally processed food, wild fruits, vegetables and different animal food. The control group (CG) was instructed to follow their normal diet. Between the test trials all participants completed a nutrition diary and underwent identical training protocols. The test days started with venous blood sampling to determine lipid profile, glucose, electrolytes, urea and uric acid, and anthropometric measurements followed by different exercises, such as sprints, jumps and an incremental step test on a treadmill for the determination of VO_{2max}. Furthermore, they completed the 30-15 intermittent fitness test during their training sessions one day later. Additionally, an interview was performed for the determination of compliance and possible side effects. Because of illness, injury, incompatibility or an insufficient level of compliance with the intervention guidelines, five participants did not complete the study or were excluded from statistical analysis. Weight (PG: pre 65.6 ± 5.8 kg vs. post 64.9 ± 5.6 kg; CG: pre 61.6 ± 7.0 kg vs. post 61.7 ± 6.4 kg), fat mass (PG: pre 10.5 ± 0.8 % vs. post 9.9 ± 1.0 %; CG: pre 10.2 ± 1.4 % vs. post 10.7 ± 1.5 %) and metabolic blood parameters remained unaffected by the dietary intervention. Performance parameters like sprint time, jump height and endurance performance showed no significant differences within and between groups, as well as metabolic parameters during exercise. However, 4 out of 9 participants reported gastrointestinal discomfort during the paleolithic diet intervention, two complained about having headaches and two about a loss of concentration or sleeping problems. To summarize, a 4-week paleolithic diet did not affect performance or metabolic parameters during rest or exercise in young football players, but caused symptoms of discomfort in the majority of them.

ASSOCIATION BETWEEN THE JAPANESE CHILDREN AND MOTHERS ABOUT THEIR LIFESTYLE AND NUTRIENT INTAKE

KAWATA, Y., MURAKAMI, K.

Kokugakuin University

Introduction Eating habits of children are greatly affected by their parents. However, the relationship of the nutrition situation has not been much studied. The present study examined that the relationship between mothers and children about their lifestyle, preference and nutrition. Methods Thirty-two Japanese primary school children aged 8 to 11 years (19 boys, 13 girls; mean age 10.1 ± 0.8 years, percent overweight -0.2 ± 16.2 %), and their mothers (mean age 40.5 ± 3.9 years, BMI 21.1 ± 2.4 kg/m²) were searched about their lifestyle, preference and nutrition. Their lifestyle and preference were investigated by original questionnaire, and their nutrient intake were used by the brief self-administered diet history questionnaire (BDHQ; for adult, BDHQ_10y; for primary school children). BDHQ and BDHQ_10y consist of 60 questions that can answer about 15 to 20 minutes, and their reliability and validity have been described by previous study (Okuda et al. 2009; Kobayashi et al. 2011; Kobayashi et al. 2012). We examined the relationship their lifestyle, preference and nutrition, using partial correlation analysis. Results and Discussion No differences were found in height, weight, percent overweight and age between boys and girls. There were no correlations between percent overweight and BMI. Primary school children, many lifestyle and preference were significantly correlated with mother's. Children's intake of energy, protein and fat were significantly correlated with mother's, and the coefficient of correlation values were about 0.4 to 0.5. On the other hand, there were no correlations with any of the following: carbohydrate, vitamin D, vitamin B12, sodium or salt. However, most vitamins and minerals were significantly correlated between children's and mother's, and the coefficient of correlation values were about 0.4 to 0.7. These finding suggests that schoolage children's lifestyle, prefer-

ence and nutrition intake were similar to mother's. SIDE EFFECTS OF ENERGY DRINKS AND CAFFEINATED BEVERAGES

SOÓS, R.1, TÉKUS, É.2, BODÓ, D.2, WILMELM, M.2

PTE ETK Hungary

Do not insert authors here Introduction There has recently been a major growth in the consumption of products containing caffeine, such as energy drinks and energy drinks mixed with alcohol among teenagers and young adults (Gradvohl and colleagues, 2015). Not long ago caffeine appeared on the dope-list as banned performance enhancing drug. Apart from its stimulant effect it can cause numerous unpleasant symptoms. Several studies describe, that high caffeine dose contributes to cardio-vascular, neurological, metabolic problems (Ibrahim-Iftikhar, 2014). Energy drinks combined with alcohol increase consumers' desire for alcohol (McKetin-Coen, 2014). Method In our quantitative research we examined 1459 persons. The target-group was the of 10-26 year old population, chosen randomly (mean age: 15,6±3,8 year). The survey was based on questionnaire and asking people about their energy drink consumption habits and their possible side-effects. Results According to the collected data 81,8% of the participants have consumed at least once energy drink, 63,3% has tried several products of the kind. 75,4% of the energy drink consumer are young, from 10 to 17 years old. 21,1% of the studied population mixes it with alcohol, 1,7% it with other caffeinated drinks. 19,8% consumes it on a daily basis, 23,1% more than once in a week, while 39,3% drinks it very rarely. 67,1% experienced unpleasant symptoms, 42,7% complained about more than one side-effects, such as rapid Heart Rate (51%), insomnia (38,8%), weakness, shiver (25,4%), headache (21,4%), in some cases even loss of consciousness. These symptoms or syndromes occurred among 86,5% of the participants, who were mixing energy drinks with alcohol, and affected 95% of those consuming more caffeinated products at a time. After collecting these data now we study the immediate physiological effect of different caffeinated drinks in 18-26 year olds adults under exercise load (leg 20m Shuttle Run test). Heart rate changes and the status of the vegetative system are analyzed. Furthermore the impacts of these products in terms of coordination and reaction time are also investigated. Conclusion The results show that high proportion of the 10-26-year-old participants consumes energy drinks and even mixed with alcohol, leading in many cases to harmful side-effects of caffeine overdose. THE EFFECTS OF RED GINSENG INTAKE ON CENTRAL AND PERIPHERAL FATIGUE IN TRAINED MICE

HYEJUNG, H., JISU, K., JONGHOON, P., KIWON, L.

Konkuk University

Introduction Fatigue is mainly divided into central nervous system fatigue, which the cerebrum perceives, and peripheral fatigue, which occurs in muscle and nerve tissues. There are a few natural substances that are so-called adaptogen in Korea, including Korean ginseng and red ginseng (RG), as well as other familiar medicinal herbs. This study aims to analyze energy utilization from the combination of RG administration and exercise, and to investigate the mechanism and the effect of RG administration on exercise-induced fatigue by analyzing 5-HT mRNAs, a central nervous system fatigue factor that is induced exercise, energy utilization during exercise (a peripheral fatigue factor), and change in mRNA related to energy control through 2 weeks intervention of RG and treadmill training in an animal model. Methods Seven-week old male ICR-mice were randomly divided into 2 groups, CON-Tr (CON-Tr, no RG administered with treadmill exercise training, n=24) and RG-Tr (RG-Tr, RG administered with treadmill exercise training, n=24). Red ginseng extract (RG) dissolved in distilled water was administered to the RG group daily at a dose of 1 g/kg body weight for 2 weeks. The gene expression was determined by semi-quantitative analysis using RT-PCR. Results The expression of Tph-2, 5-HTT mRNAs in brain region was not different between the two groups. Also, the levels of 5-HT1A and 5-HT2A receptor mRNAs were no significant differences between the groups. The changes of GLUT4, MCT4 and FAT/CD36 mRNA expression in gastrocnemius, did not significantly different between the groups. But the expression of MCT1 and CPT1b mRNA tended to be higher in the RG-Tr group 1 hour after exercise and at recovery points. Discussion Fatigue is a warning signal not only for the brain, but also for muscles and other organs that signal the body's needs for rest [1][2]. Peripheral fatigue is mainly caused by depletion of stored energy in peripheral tissues[3]. Thus, to increase the ability to exercise efficiently it is necessary [1] to increase stored glycogen in the liver and muscle, [2] to promote oxidation of stored fat, and [3] to promote blood circulation. Therefore, in our results, the intake of RG is considered to be an effective ergogenic aid in improving endurance exercise ability. From this study, further research looking for a supplement (ergogenic aid) that helps improve exercise ability is still required. References [1] Shulman RG, Rothman DL. (2001). EIGHT WEEKS ORAL GREEN TEA EXTRACTS SUPPLEMENT INFLUENCED ENERGY METABOLISM DURING HIGH INTENSITY CYCLING EXERCISE IN HUMANS

TSAO, J.P.1, HSU, M.D.1, CHENG, I.S.2

1.National Taiwan Normal University/NTNU Taipei Taiwan/ 2. National Taichung University of Education/NTCU Taichung Taiwan

Introduction Green tea contains GTEs of polyphenolic flavonoids known as tea catechins (TC), which comprise epigallocatechin gallate (EGCG) and epicatechin gallate (ECG). Most of studies showed that Green tea extracts (GTEs) are able to enhance energy expenditure and antioxidant capacity in humans (Kuo et al., 2015; Venables et al., 2008). Previous studies showed that GTEs enhanced fatty acids oxidation to promote fat metabolism on moderate-intensity exercise in regularly trained subjects (Venables et al., 2008). Little study is regarding to whether short term oral GTEs supplementation can influence energy metabolism during high intensity exercise. Therefore, this

study investigated energy metabolism, fat oxidation, carbohydrate oxidation and blood biomarkers to demonstrate the influences of oral eight weeks supplementation during 75% peak VO₂ 60 minutes high-intensity cycling exercise. Methods Eleven healthy male subjects (aged 22.0 ± 1.06 years old; height 172.7 ± 1.08 cm; weight 67.0 ± 3.4 kg; BMI 24.25 ± 0.76; VO_{2max} 43.23 ± 2.41 ml/kg/min) were participated in this crossover designed study, and considered them as GTE or placebo trials. Participants in respective trials consumed eight-week either 500 mg GTEs (375 mg Polyphenols & 125 mg EGCG) or placebo, and then completed 60 minutes with 75% VO₂ max cycling exercise. Subjects were crossed-over and repeated the study 28 days after washout period. Simultaneously, expired gas and blood samples were measured during the exercise periods for all subjects. Results Lower respiratory exchange ratio was found immediately after exercise in GTE trial, based on exchange gaseous measurement. Therefore, higher fat oxidation response was found in this study after GTE supplementation. However, no effect of eight weeks of GTEs on blood markers of lipolysis compared to placebo trials. Interestingly, higher total energy expenditure was found in GTE trial compared to placebo trial. Discussions This study demonstrated that oral eight weeks GTE supplementation influenced energy metabolism including energy expenditure, fat oxidation and carbohydrate rates based on exchange gaseous measurement following a 75% peak VO₂ 60 minutes high-intensity cycling exercise. Randell et al. found that no effect of 1 or 7 day of GTE ingestion on fat oxidation during 60-min cycling exercise with 50% Wmax (Randell et al., 2013). However, all results of this study were consistent with the evidences in previous human studies (Kuo et al., 2015; Venables et al., 2008). Our study demonstrated eight weeks oral GTE supplementation influenced energy metabolism during a 60-min with 75% VO_{2max} cycling exercise challenges in humans. PANACEO SPORT SUPPLEMENTATION SHOWS NO EFFECT ON BLOOD LACTATE CONCENTRATION AND ENDURANCE PERFORMANCE

WALLNER, D.1, MEYER, N.2, SIMI, H.1, HOFMANN, P.3

1: FH JOANNEUM Univ. Appl. Sci, 2: Univ. of Colorado, 3: Univ. of Graz

Introduction: Panaceo Sport is a dietary supplement based on zeolite (71.7%). Further components are dolomite (18.3%), lepidium meyenii (6.7%) and royal jelly (3.3%). Zeolites are microporous, aluminosilicate minerals that can accommodate cations. Panaceo Sport is taken by athletes to reduce blood lactate concentration (La) and to enhance endurance performance. Aim of this study was to evaluate these properties. **Method:** 16 trained male cyclist (VO_{2max}: 52.7 ± 6.0 ml/kg/min) performed an incremental exercise test (starting workload of 100 W was increased by 20 W every minute) at the beginning (pretest) and at the end of two supplementation phases. Randomized, Panaceo Sport or placebo was taken in the first and changed vice versa in the second supplementation phase (cross over). Each supplementation phase was 2 weeks. Placebo was siliceous earth (96.0%) and lycopodium (4.0%). First (LTP1) and the second lactate turn point (LTP2) were defined as reported by Hofmann & Tschakert (2011). **Results:** La at rest (0.83 ± 0.36 mmol/l, 0.98 ± 0.35 mmol/l and 0.97 ± 0.30 mmol/l, respectively), 100 W (0.95 ± 0.26 mmol/l, 0.93 ± 0.24 mmol/l and 0.98 ± 0.22 mmol/l, respectively), LTP1 (1.28 ± 0.27 mmol/l, 1.24 ± 0.27 mmol/l and 1.33 ± 0.33 mmol/l, respectively), LTP2 (3.19 ± 0.67 mmol/l, 3.27 ± 0.64 mmol/l and 3.25 ± 0.56 mmol/l, respectively) and termination of test (9.84 ± 1.64 mmol/l, 9.97 ± 2.06 mmol/l and 10.57 ± 1.60 mmol/l, respectively) showed no difference ($p>0.05$) between pretest, Panaceo Sport and placebo. Power output at 2 mmol/l (256.3 ± 37.0 W, 259.4 ± 38.0 W and 258.6 ± 39.3 W, respectively), 4 mmol/l (303.7 ± 36.8 W, 308.6 ± 39.3 W and 304.4 ± 39.3 W, respectively), LTP1 (213.8 ± 24.2 W, 216.4 ± 23.9 W and 213.8 ± 24.2 W, respectively), LTP2 (290.9 ± 36.1 W, 295.9 ± 34.2 W and 293.6 ± 38.5 W, respectively) and termination of the tests (362.5 ± 41.2 W, 369.4 ± 42.2 W and 370.0 ± 41.3 W, respectively) was unchanged ($p>0.05$). No difference ($p>0.05$) was also found in VO_{2max} (3.826 ± 0.536 l/min, 3.889 ± 0.586 l/min and 3.792 ± 0.621 l/min, respectively). **Conclusion:** Independent studies are needed to analyse publicized effects of dietary supplements. In this study Panaceo Sport showed no effect on blood lactate concentration and endurance performance. Further studies are needed on zeolite based dietary supplements. FRUCTOSE SUPPLEMENTATION ABROGATES EXERCISE INDUCE CHANGES IN IRON METABOLISM

TOMCZYK, M., KORTAS, J., FLIS, D., KACZOROWSKA, B., ANTOSIEWICZ, J.

Gdansk University of Physical Education and Sport

Introduction: Exercise has been shown to induce changes in iron metabolism mainly by inducing increase in blood hepcidin. Hepcidin limits intestinal iron absorption thus it has been reported that physically active people are characterised by lower body iron stores. Study on animals demonstrated that fructose can affect iron metabolism leading to its liver accumulation. In this study we hypothesise that diet rich in simple sugars like fructose or glucose will modulate the effects of exercise on iron metabolism. **Methods:** 17 young men (21 ± 1 years old) took part in the experiment. The participants were divided into following sub-groups fructose (GF) and glucose (GG) supplemented. All of them received the same diet for 3 days supplemented with fructose (4g/kg b.w) or glucose (4 g/kg b.m.) respectively. Aerobic test was performed at the beginning of the study and after three days of sugars supplementation. Blood was collected from an antecubital vein before and 1 hour after aerobic test. The serum hepcidin and genetic testing for HFE mutations (H63D) was performed. **Results:** In the present study we demonstrate that 3 days sugar diet when enriched in fructose or glucose abrogates exercise induced increase in blood hepcidin concentration. Moreover, we observed that exercise induced rise in blood hepcidin even in subjects who are heterozygotes for HFE mutations. **Discussion:** To the best of our knowledge this is the first study which demonstrate that diet rich in simple sugars like fructose and glucose modified iron metabolism. It is important to note that exercise induced rise in blood hepcidin is usually not observed in all subjects [1]. This study suggests that diet but not HFE mutation could be responsible for this.

LOW DOSE OF CAFFEINE INGESTION OF 3 MG/KG BODY WEIGHT DOES NOT ENHANCE RESISTANCE EXERCISE PERFORMANCE

ERSVÆR, E., SJØHOLT, G., IVERSEN, V., KRISTOFFERSEN, M.

Bergen University College of Applied Sciences

Introduction: In competing sports, caffeine has been widely used to improve performance. Previous studies suggest that ingestion of caffeine enhances performance in resistance exercise [1-5]. In contrast, research suggests that administration of low doses of caffeine does not enhance resistance exercise performance [6,7]. The aim of this study was to determine the acute effects of low dose of caffeine ingestion on resistance exercise performance. **Methods:** Thirteen well-trained individuals (13 males, mean age 26 ± 3.8 years, weight 86.3 ±

11,2 kg, height 183 ± 5,7 cm) ingested a caffeinated (3 mg/kg) or placebo solution, in a randomized, double-blind, cross-over procedure, 60 minutes before completing a bout of resistance exercise. Experimental conditions were separated by 48 hours. Resistance exercise sessions consisted of squat and bench press exercise to failure at an intensity of 80% and 60% of 1 repetition maximum. Serum levels of caffeine, plasma and capillary levels of lactate before and after resistance exercise was measured together with complete blood count with five-parts differential of leucocytes, in addition to components of neutrophil extracellular traps. Results: proved a significantly increase of caffeine in serum after ingestion of a caffeinated (3 mg/kg) solution. The serum caffeine concentration when the participant ingested placebo solution was equal to the control serum samples before ingestion. Results indicate that participants' rating of perceived exertion (RPE; 6-20 Borg scale) were equal and completed equal repetitions to failure, irrespective of exercise, in the presence of caffeine or not. No significant differences in peak heart rate and peak capillary whole blood lactate values were observed. Venous plasma concentration of lactate increased significantly after resistance exercise for all participants, however, the increase was not significantly different when comparing the placebo trial with the caffeine trial. This was also true when analyzing hemoglobin, hematocrit and leukocyte particle concentration. Discussion: low dose of caffeine ingestion of 3 mg/kg does not enhances resistance exercise performance. 1 Duncan, M. J., et al. Eur J Sport Sci 13, 392-399, (2013). 2 Duncan, M. J. & Oxford, S. W. THE EFFECT OF TRAINING AND MICROBIOME CHANGES IN CELL METABOLISM

SZENASI, N., RADAK, ZS.

University of Physical Education

Introduction The positive effect of physical activity on human health has been well documented. It helps to prevent obesity, cardiovascular diseases and diabetes. As a result of physical activity increased concentration of free radicals can be detected this plays an important role in the adaptation process of the antioxidant system, by eliminating the oxidative damage. Recent study has shown that exercise in early life alters the guts micro flora leading a better brain and metabolic activity. It reduces anxiety and depressive behaviours, inhibits fat accumulation and plays an important role in colorectal cancer prevention. Certain (strains of) bacteria are able to convert the fibre to butyrate, which is an energy source for colon cells. Agar, - a compound extracted from red algae (*Rhodophytal*) - can contain up to 80% of fibre and may provide energy. The aim of this study is to investigate the effect of the long-term high-intensity interval running exercise and agar supplementation on gut micro flora changes and cell metabolism. Methods 36 young female Wistar rats were assigned to four groups: control group, a group with agar treatment, training group and complex (agar and training). After 20 weeks of treatment cognitive tests (open field, Morris maze, passive avoidance test) were performed and tissues (brain, liver, skeletal muscle, gut) were collected for further use. Results According to our findings the training group's body weight was significantly higher than the group with agar treatment. In the passive avoidance test the treated groups showed better performance than the control group. The open field and Morris maze tests didn't reveal any significant difference. Discussion For a more detailed conclusion further investigation is needed. We are aiming to measure the changes in guts microflora, free radical concentration and mitochondrial biogenesis markers. NICOTINAMIDE TREATMENT ALTERS THE CONTENTS OF CELL METABOLISM REGULATING PROTEINS IN GAS-TROCNEMIUS MUSCLE OF YOUNG AND OLD RATS

MELITTA, P., RADÁK, ZS.

University of Physical Education

INTRODUCTION Sirtuin proteins are member of histone deacetylases, but they readily remove the acetyl group from the lysine residues of all kinds of proteins. This transformational modification influences the activity of enzymes and the stability of proteins. Sirtuins play an important role in aging and different kind of diseases, because sirtuins control cellular metabolism, antioxidant and oxidative damage repairing systems. Physical exercise has been shown to modulate the content and activity of the sirtuin enzyme family. Sirtuins are NAD dependent enzymes and the hydrolysis of NAD results in deacetylated protein, O-acetyl-ADP ribose, and nicotinamide (NAM). Nicotinamide as a result of feedback mechanism inhibit the activity of sirtuins. The aim of our investigation was to inhibit SIRT1 by administration of nicotinamide on exercising rats, to study how sirtuins are related to exercise-induced adaptation. METHODS In our study, we worked with 24 old (28 month old) and 24 young (4 month old) female Wistar rats. The animals were divided into eight groups (n=6): control old, trainer old, nicotinamide treated old, combined old, control young, trainer young, nicotinamide treated young, combined young. Animals were subjected to treadmill running 5times week for 6weeks. The intensity of the running was low (10m/min) with the duration of 1hr at the end of the last week. Nicotinamide was placed in the drinking water treatment was every day. We used 1% nicotinamide dilution for 4 weeks, then we decreased for 0,5%, because 1% caused significant loss of body mass. The quantitative analysis of proteins were carried out by Western blotting, the mRNS levels were assessed by PCR, and the activity level of proteins by spectrophotometry. Results and Discussion NAM treatment significantly reduced the body mass of the animals. The protein content of SIRT1 decreased significantly in complex groups compared to control levels. Nicotinamide phosphoribosyltransferase (NAMPT) is important enzyme to the biosynthesis of NAM and our data revealed that aging results in significant loss in the levels of NAMPT. NAM treatment alone and with training significantly increased the levels of 5'AMP-activated protein kinase (AMPK) compared to trained and control groups. AMPK can directly activate PGC-1 α , which is the master regulator of the mitochondrial biogenesis. In this study we report that PGC-1 α levels increased significantly in NAM supplemented old group compared to age-matched trained and control groups. Our findings so far suggest that NAM supplementation causes weight loss, which is associated with alteration of cellular metabolism regulating proteins like AMPK, PGC-1 α . Our data revealed, that aging has significant effects on how the body copes with NAM treatment.

EFFECT OF BLACK TEA DERIVED HIGH-MOLECULAR-WEIGHT POLYPHENOL ON FUNCTIONAL OVERLOAD IN MICE

AOKI, Y.I., OZAWA, T.I., TAKEMASA, T.2, NUMATA, O.1

University of Tsukuba

Introduction It has been reported that polyphenols have some good effects on skeletal muscle. In our laboratory, we extracted high-molecular-weight polyphenols from black tea, and named it Mitochondria Activation Factor (hereafter, MAF), because MAF enhanced mitochondrial membrane potential of ciliated protista *Tetrahymena pyriformis* (Fujihara et al.). We found MAF raise AMPK (regulator of

PGC-1 alpha, which stimulates mitochondria biogenesis) phosphorylation level and improves endurance performance in mice (Eguchi et al.). Recently, in order to use MAF for supplement, we extracted crude MAF fraction with 80% ethanol, and named this E80. In this study, we examined whether E80 affects on mice skeletal muscles during functional overload, which is an imitation of resistance training in human. Purpose To investigate whether E80 has some effects on hypertrophy process of mice skeletal muscles during functional overload Methods Adult mice (8 weeks of age) fed on food containing E80 for a week before functional overload. After one week pre-feed, we removed synergist muscles (gastrocnemius and soleus) and remained plantaris. Following 4 day, 7 day, 14 day of functional overload, mice were euthanized by cervical dislocation and excised plantaris muscle. Results We investigated the phosphorylation level of signal molecules and found some molecules were activated by administration of E80. Discussion Previously, Eguchi et al. reported MAF improved mice endurance performance in mice. In this study, we demonstrated E80 improved resistance training effect too. Reference Fujihara et al. EFFECTS OF CREATINE SUPPLEMENTATION ON SPRINT PERFORMANCE IN YOUTH, ELITE FOOTBALL PLAYERS

HORNE, S., SIMPSON, A.J., SHARP, P., FARRIER, G., SHARPS, R., KIPPELEN, P.

Brunel University

Introduction Creatine is a highly popular food supplement in football (Waddington et al., 2005). Whilst a wealth of data exists on the ergogenic effects of creatine supplementation in senior players, limited data are available in youth players. Therefore the aim of this study was to examine the effects of a standard, 8wk course of oral creatine monohydrate (CM) supplementation on sprint performance in youth, elite football players. Methods Fifteen U18 (age 16 to 18 yr), male, Football Academy players followed a randomised, double-blind, placebo-controlled, parallel-group trial during the early competitive season. Players ingested 0.3 g/kg/d of CM (n=7) or placebo (PLA, n=8) during a 1wk loading phase, followed by 5 g/day of CM or placebo during a 7wk maintenance phase. Pre- and post-supplementation participants underwent body composition assessment (via body mass and sum of 8 skinfold thicknesses) and performed a repeated-sprint ability (RSA) test (Rampinini et al., 2009). In a subgroup of 10 outfield players (4 on CM and 6 on PLA), GPS data were obtained during match play in the period leading to the supplementation period and in weeks 4 to 8 of the supplementation period. Key index of sprint performance was % of overall match distance covered at >19 km/h (Osgnach et al., 2010). Data are presented as mean +/-SD, compared by RM-ANOVA. Results Body mass did not significantly change over the course of supplementation in either group. A small but significant ($P=0.007$) decrease in skinfold thickness was observed post-supplementation, with no group difference (-7+/-4% in CM and -5+/-8% in PLA). RSA did not significantly improve post-supplementation (mean RSA time pre- vs post-supplementation: 7.57+/-0.18 vs 7.52+/-0.22 sec in CM; 7.44+/-0.30 vs 7.24+/-0.18 sec in PLA). Sprint performance during competitive match play did not significantly differ pre- to post-supplementation, or between groups (overall match distance covered at >19 km/h: pre 4.8+/-0.7 and post 5.6+/-1.6% in CM vs pre 7.3+/-2.8 and post 7.2+/-2.9% in PLA). Discussion In youth, elite players 8wk of CM supplementation did not induce muscle mass gain beyond that observed with training alone. Further, CM did not significantly improve sprint performance. Thus these findings cast doubt about the effectiveness of CM as an ergogenic aid in youth, elite football. References Osgnach C, Poser S, Bernardini R, Rinaldo R, di Prampero PE (2010). THE INFLUENCE OF ACUTE DIETARY NITRATE SUPPLEMENTATION ON PERFORMANCE DURING A SOCCER SPECIFIC TREADMILL PROTOCOL

PETERS, G., HENDERSON, K., STONE, M.

Bucks New University

Introduction Research shows that dietary nitrate supplementation (DNS), reduces the O₂ cost of walking and running (Lansley et al. 2011). Further research suggests that DNS reduced the O₂ cost of low intensity exercise, and enhanced tolerance to high intensity exercise (Bailey et al. 2009). Field based research has shown that DNS improves intermittent running performance by around 3.8% when time to fatigue is assessed (Wylie et al. 2013). However no studies so far have examined the effect of acute DNS on the physiological responses to high intensity interval exercise (HIE). Therefore the aim of the study is to show the effects of DNS on high intensity intermittent running. Methods Participants visited the Human Performance Laboratory (HPL) four times. The first visit was a maximal oxygen uptake (V' O_{2max}) test, to volitional fatigue. Following a pilot session, the participants then performed two exercise tests 10 days apart, in a doubly blind randomised crossover design. Participants ingested a 70 ml shot of Beetroot juice (BRJ) containing 0.4 g (4mmol) of dietary nitrate, or 70ml placebo (PL) 60 min prior to an intermittent treadmill protocol. Results At time of submission, seven participants completed study. Mean Oxygen uptake (V' O₂) was 36.6 and 36.2 ml.kg.min⁻¹ between BRJ and PL respectively. Mean blood lactate concentrations are 4.89 and 5.76 mmol.L⁻¹ for BRJ and PL respectively. Mean blood glucose concentrations are 4.38 and 4.46 mmol.L⁻¹ for BRJ and PL respectively. Perceptual responses are 13 v 12 for BRJ and PL respectively. Discussion Early results suggest that acute dietary nitrate supplementation reduces the perceptual effort of high intensity exercise, despite no changes in oxygen consumption. Blood lactate and glucose also show no differences between BRJ and PL respectively. Further data to be collected to ensure type I or II errors are not made. References Bailey, S. J., Winyard, P., Vanhatalo, A., Blackwell, J. R., DiMenna, F. J., Wilkerson, D. P. Jones, A. M. (2009). DIETARY VITAMIN D INTAKE, SERUM VITAMIN D CONCENTRATION, AND MUSCLE STRENGTH OF COLLEGIATE FEMALE BASKETBALL PLAYERS IN JAPAN.

NAGANO, M.

Keio University School of Medicine

BACKGROUND & PURPOSE: Vitamin D is one of the substances involved in bone metabolism, besides, vitamin D receptor expresses on several organs and it has been shown that vitamin D play many positive roles in human body (Cannell, 2009). It is reported that vitamin D

supplementation in older individuals improved muscle strength and mobility(Zhu, 2010), and serum vitamin D concentration respond to vitamin D supplementation in a dose-dependent manner(Heaney, 2003). The aim of this study is to investigate and assess relationships between Vitamin D intake, serum Vitamin D concentrations, and muscle strength of collegiate female basketball players in Japan (FBPJ). METHODS: The subjects were eleven FBPJ. We used Food Frequency Questionnaire designed for vitamin D intake (Uenishi, 2008). Blood test of serum 25(OH) D was performed and quadriceps strength was measured with Biomedex. Regression analysis was done for the assessment of correlations between dietary Vitamin D intake, serum 25(OH)D, and quadriceps strength. RESULTS: FBPJ had enough intake of vitamin D(mean 410.9 ± 86.3 IU), however, almost all FNPJ had low concentrations of serum 25(OH) D (mean 19.2 ± 2.9 ng/ml). Regression analysis revealed no significant correlations between dietary Vitamin D intake, serum 25(OH)D, and quadriceps strength. DISCUSSION: FBPJ had enough vitamin D intake, but almost all of them had low vitamin D concentrations. It seems that the lack of sun exposure has a negative effect on maintaining serum vitamin D concentrations. To maintain optimal serum vitamin D concentrations, sun exposure may be more effective than nutritional intervention for Japanese female athletes. This study could not reveal the relationships between dietary vitamin D intake, serum 25(OH)D, and muscle strength. It seems to be mainly because of small sample sizes. Further studies containing enough sample sizes are needed. REFERENCES: Cannell, J., Hollis, B., Sorenson, M., Taft, T. & Anderson, J. (2009). Medicine and science in sports and exercise, 41, 1102–10. EFFECT OF HIGH-FAT DIET AND INSULIN DEFICIENCY ON METABOLISM OF BIOACTIVE SPHINGOLIPIDS IN DIFFERENT BLOOD COMPARTMENTS.

GORSKI, J., BLACHNIO-ZABIELSKA, A., ZABIELSKI, P., CHABOWSKI, A.

Department of Physiology, Medical University of Białystok, Białystok, Poland

Bioactive sphingolipids play very important regulatory role in the body. There are data indicating that exercise affects metabolism of the sphingolipids not only in skeletal muscles but also in different blood compartments (1,2,3). However, factors regulating metabolism of the blood sphingolipids is very poorly recognized. The aim of the present study is to examine effect of high-fat diet and insulin deficiency on the level of different bioactive sphingolipids in plasma, erythrocytes and platelets. Methods The experiments were carried out on three groups of rats, 280-300g of body weight: 1-control, 2- fed on high-fat diet (HFD), 3- with insulin deficiency (streptozotocin diabetes, STD). Sphingolipids were extracted from plasma, erythrocytes and platelets. The following sphingolipids were analyzed by mass spectrometry: eight ceramides (CER), sphinganine (SA), sphingosine (SE) and sphingosine-1-phosphate (S1P) (2). Plasma insulin and blood glucose level was also determined. Results Plasma. The diet elevated the level of SA, SE and reduced the total level of CER (it was the sum of individual CER). STD did not affect the plasma level of either compound determined. HFD increased and STD markedly reduced the plasma insulin concentration. Erythrocytes. HFD reduced the level of SA and SE and increased the level of S1P. STD elevated the level of SE, S1P and total CER. Platelets. HFD increased the level of each compound with the exception of S1P. STD reduced the level of SA and SE. Discussion The source of plasma sphingolipids is different. CER is secreted by the liver, SA and SE come from solid tissues and S1P is released mostly by erythrocytes, platelets and endothelial cells. Regarding CER, we found that behavior of particular ceramides is not uniform but depends both on a type of ceramide and the blood compartment. It would indicate on selective metabolism of the compounds in the blood compartments. The blood cells do not have an ability to synthesize sphingolipids de novo. They take up plasma SE, phosphorylate it and release into the plasma. The elevation of S1P in erythrocytes with concomitant reduction in the content of SE would indicate increased phosphorylation of the latter compound by HFD. The results obtained in STD indicate on a role of insulin in regulation of sphingolipid metabolism in different blood compartments. Conclusion: Both HFD and severe reduction in the plasma insulin level affect metabolism of sphingolipids in plasma, erythrocytes and platelets. 1. Baranowski et al. COMPARISON OF BADMINTON LONG SERVE BETWEEN SKILLED PLAYERS AND BIGGINERS IN PHYSICAL EDUCATION CLASS

SUDA, K.1, TANIGAMI, T.1, KODERA, T.1, USUI, S.2, FUJIMOTO, M.2, UMEBAYASHI, K.3

1:Tokyo Institute of Technology, 2:Tokyo International University, 3:Osaka University of Health and Sports Sciences

Introduction Long service is a fundamental skill in badminton with which rallies start. But stroke production of long serve is somewhat difficult for beginners. If the serve flight length is short, the rally will be disadvantageous for the server. Therefore, we compared long serve between skilled players and beginners in PE class to find important elements. Methods All participants were university students who attended badminton (physical education) class. 15 skilled players and 15 beginners were selected from these students by the initial shuttlecock speed of long serve all participants were right handed. Participants were asked make long service from the right side of the badminton court to the target placed on the back boundary line and center line of the opposite court. They tried 5 times and successful services were analyzed. The players' motions were recorded with 4 cameras 300 frames per second. The control points were recorded before making the services. 3 dimensional coordinates of the shoulders, the right elbow, the right wrist, racket head of the servers were calculated with computer software. We defined the start of the forward swing as the time when the racket head vertical speed changed to downward. We used t-test for the statistical comparison between the two groups and considered significant if $p < 0.05$. Results Average initial shuttlecock speed was significantly higher in the skilled players (15.7m/s) than the beginners (10.8m/s). Increment of speed from the right shoulder to the right elbow was significantly larger in the skilled player than the beginners at the start of forward swing but similar at impact. Increment of speed from the right elbow to the right wrist was also significantly larger in the skilled player than the beginners at the start of forward swing but not significant at the impact. In contrast, increment of speed from the right wrist to the racket head was not significantly different at the start of forward swing but significantly larger in the skilled player than the beginners at impact. Discussion We focused on the increment of speed from proximal point to distal point for the servers. Speed increment was larger in the skilled player from the shoulder to the wrist at the start of forward swing. These results suggest the skilled server can accelerates speed from the prox-

imal points to distal points from forward swing start to the impact. In the beginners, acceleration was especially weak at the start of forward swing, this resulted small speed increment from the wrist to the racket head. Wang et al.,(2009) reported beginners tend to use elbow flexion and extension only for overhead strokes. In accordance with their study, although participants performed underhand service, beginners tended to use simple segmental movement which caused less speed increment from proximal to distal point than skilled servers. Reference Wang, J. et al. Steps for arm and trunk actions of overhead forehand stroke used in badminton games across skill levels Perceptual and Motor Skills, 109,177-186, 2009.

THE RELATIONSHIP BETWEEN MOTOR PERFORMANCE AND ATTENTION PERFORMANCE AMONG 11-12 YEARS OLD AUSTRIAN STUDENTS

GERHARD, R., HOLLAUS, M., GREIER, K., KOPP, M.

University of Innsbruck

Introduction Studies suggest that there is a positive association between participation in physical activity and cognitive performance (Etnier et al., 2006). Therefore the aim of this study was to investigate the relationship between motor performance and attention among 11-12 years old Austrian students. Methods Height, weight and motor performance among 255 11-12 years students (57% males,) were measured using the German motor performance test DMT 6-18 (Bös and Schenker 2011) delivering age- and gender-related z-parameters of 20-meters-sprint (ZSp20m), backward balancing (ZBall), jumping sideways (ZSHH), stand-and-reach (ZRB), push-up (ZLS), standing long jump (ZSW) and 6-minute run (ZL6Min), and total motor performance (ZGes). In addition, students completed the d2-test of attention (Brickenkamp and Zillmer 2002). To assess the relationship between motor performance and attention, correlation analyses between the values for the total motor performance (ZGes) and for each single motor test item with the total attention performance value (KL) were conducted. Results Correlation analyses showed significant relationships between the attention value KL and total motor performance value ZGes ($r=.218$) as well as between KL and ZSp20 ($r=.162$), ZSHH ($r=.200$), ZRB ($r=.152$), ZLS ($r=.167$), ZSU ($r=.228$), and ZSW ($r=.132$), respectively. Discussion Among this cohort of secondary school children small but significant positive correlations between attention and total motor performance as well as between attention and 6 out of 8 motor test items were detected. In accordance, Vanhelst et al. (2016) found that the attention capacity of adolescents (measured via d2-test of attention) was significantly and positively associated with longer time spent in moderate or moderate-to-vigorous physical activity in free-living conditions. Ericsson and Karlsson (2014) found that daily physical education lessons during compulsory school years improved not only motor skills but also school performance and the proportion of pupils who qualified for upper secondary school. Therefore, an increase in physical activity and motor performance through an increased number of physical education lessons in school settings may be beneficial not only for health reasons but also for cognitive performance and academic achievement of adolescents. EFFECT OF THE SENSORY INTEGRATION THERAPY ON POSTURAL STABILITY IN CHILDREN 4-6 YEARS OLD

MACIASZEK, J., KILAN, N., OSIŃSKI, W.

University School of Physical Education in Poznan

The aim of research was to examine the influence of sensory integration therapy (SIT) on one leg standing test in children with very low level of postural stability. Twenty eight children between the ages of 4 – 6 participated in this study. Children that could not stand on one leg for more than 20 seconds were randomly divided into two groups – control "C" (7 boys and 7 girls) and experimental "E" (8 boys and 6 girls). Children from group "C" participated in standard classes in the kindergarten and did not make any changes to their daily routine. Children from group "E" participated in SIT for 2 weeks (additionally to the standard classes). Therapy was conducted 5 times a week. Each session lasted 30 minutes. Postural stability in children was measured with use of one leg standing test. The test always was performed in the same sequence: 1) on the right leg with eyes open, 2) on the left leg with eyes open and 3) on the right leg with eyes closed, 2) on the left leg with eyes closed. The change in time of standing on the right leg with eyes open in the "E" group was statistically significantly higher than the changes observed in the same time in group C ($F = 22.5$, $p = 0.001$, $\eta^2 = 0.44$). Results of standing on the right leg with eyes closed in group "E" were higher in group "E" than in group "C" ($F = 16.1$, $p = 0.004$, $\eta^2 = 0.36$). Similar results were observed during on the one, left leg standing. The time of one leg standing with both eyes open and closed improved more significantly in group "E" than in group "C" ($F = 20.4$, $p = 0.001$, $\eta^2 = 0.42$ respectively for the test with eyes open and $F = 7.4$, $p = 0.010$, $\eta^2 = 0.21$ for the test with eyes closed). The positive influence of SIT on children with low level of postural stability was observed. Its statistically significant improvement in children is important not only for the current functioning of those children but for their future. Good level of postural stability can help children develop their gross motor skills and be more active. Staying active through gross motor exercise can also help children avoid the obesity that can come through inactivity.

THE EFFECTS OF A SPORTS GAME-ORIENTATED EXERCISE PROGRAM ON PEOPLE WITH MENTALLY DISABILITY - A PILOT STUDY

BELLER, R., SCHWAB, S., KIRMSE, M.

German Sport University Cologne, Ruhr-University Bochum

Motor abilities and concentration skills are critical factors while working with people with intellectual disabilities and can be improved by specific sport programs such as the Ballschule Heidelberg [1]. Their program was created in order to improve children's technical, tactical and motor abilities. The aim of this study is to evaluate the efficacy of this specific program on concentration and coordination skills in people with intellectual disabilities. 12 adults participated in this study (6m/ 6w; 29.9 ± 11.4 y) and were divided into two groups (group 1: 1m/ 3w, 34.0 ± 16.7 y; group 2: 5m/ 3w, 27.9 ± 8.4 y) by their level of disability (group 1: mental disorders, group 2: learning disabilities). Subjects were tested prior and after the intervention of 6 weeks (1-d/w for 45 min) with the d2 [2] and KTK [3] test. D2 showed no differences over all subjects in the concentration capacity ($p \geq 0.05$). However, an increase in concentration capacity was recorded in group 2 (81.5 ± 33.1 vs. 101.4 ± 45.3 , $p = 0.065$). Whereas the processing speed of group 2 increased significantly (343.3 ± 78.0 vs. 405.0 ± 86.4 , $p \leq 0.05$), that of group 1 remained unaffected ($p \geq 0.05$). No change between pre- and post-testing was found in KTK ($p \geq 0.05$). A higher increase in concentration capability was found in participants of group 2. Thus, the ability to improve mental and physical capacities through sport tends to depend on the degree of intellectual disability. Further studies are needed, including a larger group of participants as well as a

control group to provide definite results. [1] Roth, K. & Kröger, C. (2011). Ballschule. Ein ABC für Spielanfänger (4th ed.). Schorndorf: Hofmann. [2] Brickenkamp, R. (1994). CORE VALUES IN NOVICE PHYSICAL EDUCATION TEACHERS AND SPORT SCIENCE STUDENTS

CASOLO, F., COCO, D., COLOMBO, L., FRATTINI, G., GATTI, M., VAGO, P.

Catholic University, Milan

Introduction: The purpose of this study is to explore the values orientation of individuals (students and teachers) involved in Sport Science and Sport Pedagogy fields. Methods: 147 individuals (mean \pm SD age: 30 \pm 6.8 years, range 23-53 years, 79 females and 68 males) enrolled either in a Master's Degree in Sport Science (36.7%) or enrolled in PE Teaching specialisation courses for Secondary School (TFA 42.9%; PAS 20.4%) at the Catholic University of Milan were recruited for this study. The participants completed an ad-hoc prepared socio-anographic questionnaire and the PVQ (Portrait Values Questionnaire), a list of 40 item that describe the values of a general person and the subjects express how much they perceive themselves similar to the hypothetical person (in a Likert 6 points scale). The values orientation is organized in two bipolar dimensions: self-enhancement versus self-transcendence; conservatism versus open to change. Results: Regarding the bipolar values orientation, the sample showed higher values in self-transcendence (mean 4.77) and open to change (mean 4.39). Self-enhancement was higher in men (Student's t-Test, $p<0.01$) and in young people (Pearson's r - .334, $p<0.01$); instead self-transcendence was greater in the teachers, who were also the eldest (positive correlation with age; r .223, $p < 0.01$). Discussion: Individuals involved in physical activity seem to have a good social predisposition (prevailing values orientation of self-transcendence), especially those who chose a teaching career and are interested in other people's wellbeing. (2005), La misura dei valori. Un contributo alla validazione del Portrait Values Questionnaire su un campione italiano, *Bollettino di Psicologia applicata*, 246, 29-41.

PERSONALITY TRAITS IN PHYSICAL EDUCATION PRE-SERVICE TEACHERS AND SPORT SCIENCE STUDENTS

VAGO, P., COCO, D., COLOMBO, L., FRATTINI, G., GATTI, M., CASOLO, F.

Catholic University, Milan

Introduction: The aim of the study is to trace the personological profile of individuals involved in Sport Science and Sport Pedagogy fields (students and teachers) in order to identify their specific personality traits. Methods: A sample of 147 individuals (mean \pm SD age: 30 \pm 6.8 years, range 23-53 years, 53.7% females and 46.3% males) following a Master's degree in Sport Science (36.7%) or enrolled in PE Teaching specialisation courses for Secondary School (TFA 42.9%; PAS 20.4%) at the Catholic University of Milan, were recruited for this study. The participants completed a socio-anographic questionnaire - evaluating education and experience both in school teaching and in sports context as fitness centers and sports teams - and the BFO (Big Five Observer), a questionnaire designed to investigate the main dimensions of personality (Energy/extraversion, Agreeableness, Conscientiousness, Emotional Stability, Mental Openness) through a list of 40 pairs of bipolar adjectives. Results: The sample – comparing to general population's standardized values - shows high levels of emotional stability (T points mean 57; 58 in men) and mental openness (T higher points mean 56). Student's t-Test ($p < 0.01$) highlighted some gender differences: females presented values in conscientiousness and males in emotional stability. Instead, there were no significant differences between students and teachers about personological aspects. There was a positive correlation (Pearson's r 0.166 $p < 0.05$) between age and energy/extraversion: this dimension grew with the years. Discussion: Personological aspects are often overlooked when studying the population of sport science and sport pedagogy, but it seems important to consider this information both to understand the reason of this career choice (also comparing in the future our study population with another sample, for example of human sciences) and to define appropriate training courses in sport education field. SLEEP DURATION AND ACADEMIC PERFORMANCE IN JAPAN'S JUNIOR HIGH SCHOOL STUDENTS

NAKAJIMA, T., MORITA, N., SAGAWA, M., YAMATSU, K.

Hokkaido University of Science, Hokkaido University of Education, Japan, Saga University, Japan

Introduction. In recent years, there have been many reports on the effects of lifestyle of students on academic performance. In particular, the length of the sleep time is thought to be involved strongly with academic performance. According to Ortega et al. (2010), male adolescents who take sleep more than 8 hours have shown higher cognitive performance than others with less than 8 hours sleep. However, many of these studies were intended for children in Europe and North America, it has not been clear yet about the actual situation of children living in other cultures, including in Asia. The purpose of this study is to reveal the influences of sleep duration on the school grades as the actual academic achievement in Japanese junior high school students. Methods. Participants were 218 male students (body mass index [BMI]: 19.1+/-3.3) and 192 female students (BMI: 18.9+/-2.9) of 1st grade (7th grade in USA style) in public junior high schools in Japan. All students and their parents completed the questionnaires about their sleep duration, household income, and mother's educational background. BMI and academic performance (school grades) were received from school records. The sum total of the 9 subjects' grades (Japanese, social studies, math, science, English, art, music, Technology and Home Economics, and physical education) were used as the academic achievement score. The participants were divided into three groups according to their sleep duration separately for male and female (Group 1 < 6 hours, 6 hours \leq Group 2 < 8 hours, 8 hours \leq Group 3). Results. Using ANCOVA that controlled for covariates (household income and mother's educational background), Group 1 (less than 6 hours sleep, mean grade: 28.1+/-1.2) had significantly lower school grades than Group 2 (6-8 hours sleep, mean grade: 31.6+/-0.5, $p < 0.05$) in male students. On the other hand, in female students, there were no significant differences among the 3 groups in school grades. Conclusions: These results suggest that short sleeping less than 6 hours retard the school grades in Japanese male students. Because this result had some differences in the length of sleep duration from previous studies in Europe and the USA, we have to consider the cultural and ethnic aspects in the relationships between academic achievement and sleep duration. Sleep duration and cognitive performance in adolescence. (The AVENA Study). *Acta Paediatrica*. 99: pp454-456.

means systematically to strengthen their health-oriented recreational motion activity in later life; • showing the growth of the health self-esteem and moderate fatigue at the end of Physical Education lessons.

DEVELOPMENT OF STUDENTS' PHYSICAL EDUCATION BASED ON REMOTE TEACHING.

KOVALENKO, T., ULYANOV, D., SHKLYARENKO, A.

1. Volgograd State University (Volgograd, Russia). 2. Kuban State University, the branch in the town of Slavyansk-na-Kubani.

Introduction A promising line of development of high school students' physical education is to apply some forms and methods of students' physical education remote teaching. These require the development of appropriate electronic resources. Methods A set of theoretical (analysis and synthesis of scientific literature, generalization of advanced pedagogical experience, etc.) and empirical (pedagogical observation, questioning, pedagogical testing, pedagogical experiment, etc.) research methods was used in the work; these methods complement each other. Results The developed technology provides multiple differentiation of lessons on 'Physical Education': physical exercise (taking into account the level of physical fitness of students) and physical exercise duration (taking into account the level of students' somatic health). One of the characteristics of the technology is the modular organization of the educational process based on the following modules: M1 – «Active motivation of students to take care of their health»; M2 – «System of health and fitness self-training and self-control»; M3 – «Correctional and supporting sports and fitness activities». Each module includes a section of theoretical and methodological information and assessment procedures provided on thematic sites. Discussion The implementation of development of technology of high school students' physical education by way of health and fitness remote teaching provides gradual formation of students' physical fitness knowledge, motivation attitude towards physical education and their health, motion activity and skills for a healthy lifestyle, practice and methodical ability, etc. The work shows that the number of students with the following characteristics increased significantly within the experimental group compared to the control group: • having full knowledge system for choosing and using physical education means, content and organization of motion activity to promote health as well as acquired practical skills of personal self-esteem of physical education I

FUNDAMENTAL MOVEMENT SKILLS IN YOUNG CHILDREN FROM LOW SES: THE INFLUENCE ETHNICITY

EYRE, E.L.J., HODSON, D.A., HASSAN, H., POOLE, R., GINGER, H., POWELL, M., AJISAFE, A., HARVEY, A., DUNCAN, M.J.

Coventry University

Introduction Children from South Asian backgrounds in the UK have the lowest physical activity levels. Less active children have low levels of fundamental movement skill (FMS) competence and poorer health. While there is some evidence to suggest that age, sex, physical activity, SES is associated with FMS (Barnett et al., 2016), the role of ethnicity in FMS competence is underexplored, particularly in South Asian children. The aim of the study was to examine differences in FMS between White EU and South Asian children aged 4-5 years from low SES areas in West Midlands, UK. Methods Following ethical approval, 42 children aged 4-5 years (21 White EU, 21 South Asian, 24 male, 18 female) were recruited from low SES areas of West Midlands, UK. Each child was assessed performing 4 locomotor skills (run, gallop, hop, and jump) and 4 object skills (strike, catch, kick and overarm throw) according to the Test of Gross Motor -2 checklist (Ulrich, 2001). A 2 (sex) by 2 (ethnicity) ANOVA assessed differences in locomotor composite score, object composite score and total FMS. Significance was set at $P < 0.05$. Results Preliminary data shows, no main effect of gender or ethnicity was found for locomotor or total FMS ($P > 0.05$). A main effect of ethnicity ($P = 0.016$) and an interaction effect between ethnicity and gender ($P = .007$) was found for Object skills. Post hoc analysis following an ANOVA identified significant differences in object skills of White EU females compared to male White EU (mean difference = 5, $P = 0.10$, $d = 1.47$) male South Asian (mean difference = 4, $P = 0.009$, $d = 1.49$) and female South Asian (mean difference = 6, $P = .006$, $d = 1.86$), whereby White EU females had poorer object skills. No further significant differences were found between ethnicity and gender for object skills. Discussion The findings suggest that South Asian children irrespective of gender have better object skills than low SES matched White EU females. This is particularly interesting given that South Asian children have lower PA levels, which has previously been associated with FMS. Further research should examine the association between ethnicity, FMS, PA in a larger sample of multi-ethnic children to confirm this. Reference Barnett LM, et al. PHYSICAL EDUCATION'S STUDENTS AT THE UNIVERSITY OF BRASILIA IN VIRTUAL LEARNING ENVIRONMENT AND THE CHARACTERIZATION AND HABITS OF STUDY DURING THE COURSE

SILVA, A., MAGALHÃES, G., SOARES, J., MIRANDA, D., BENITO, L., SOUZA, S., BARROS, J., TELES, L.

University of Brasilia; Cardiology Institute of the District Federal; Federal University of Rio Grande do Norte

The students's sociodemographic characteristics in a Virtual Learning Environment (VLE) course are diversified. These, may influence the teaching-learning process in VLE. The aim of the study was to describe the characteristics of undergraduate physical education's students distance of UNB and their study habits. There were 81 students in the study. The google docs tool for data collection was used. The descriptive analysis was performed by the statistical software Minitab 17. This study project was approved by the research ethics committee in humans, Faculty of Health Sciences at the University of Brasilia (CEP / CONEP: 03/20/2014). It was observed a predominance of males (51.9%), singles (54.3%) aged over 36 years (44.4%) paid jobs (90.1%) no graduation (84%) attending more than 5 subjects (74.1%), participated in a blended course or distance (60.5%), studying on the internet (38.3%) studying off the internet (63 %) up to 6 hours per week, preferably time to study between 6 p.m to 12 a.m (60.5%) studying alone (86.4%), read just over half of the course content (49.4%). The preponderance of economic, social, demographic and educational characteristics may facilitate the teaching-learning process established in subjects and courses in the distance. However, these characteristics can help the development of strategies's mediation between the tutor and students seeking a more active and reflective participation of students. HOW DOES PHYSICAL EDUCATION AFFECT THE DEVELOPMENT OF LOCOMOTOR AND OBJECT CONTROL SKILLS IN PRESCHOOL CHILDREN

BELLAIORE, M., BATTAGLIA, G., BIANCO, A., THOMAS, E., PATTI, A., CARAMAZZA, G., ALESI, M., PALMA, A.

University of Palermo

Introduction Unlike other European countries, in Italian kindergartens the physical education (PE) teacher is not including in the school organic personnel. This is frequently associated with lack of opportunities to perform PE by preschool children. Therefore, the aim of this study was to analyse whether the effects of a PE program on the development of locomotor and object control skills in preschool children would depend on the hour amount of intervention. **Methods** This study involved 189 children (age: 4.62 ± 0.97 years; Height: 107.83 ± 7.82 cm, body weight: 19.84 ± 4.95 kg) of 8 Palermo kindergartens who were randomly divided in a control group (C, n= 29), an intervention group 1 (I1, n= 120) and an intervention group 2 (I2, n= 40). I1 and I2 children performed a PE program of 16-week length for 4 and 10 hours/week respectively (total hours: 52 and 180), carried out by PE teachers, while C children do not perform any PE program. This program was planned in 21 learning sessions aimed to develop the body schemes, basic motor skills, fine motor control, coordination abilities, confidence and autonomy, socialization, emotion and affect control. Locomotor and object control skills were evaluated with the Test of Gross Motor Development (TGM), (Ulrich, 1985) before and after PE program. Analyses of covariance (ANCOVA) were performed to compare outcomes for I1, I2 and Control groups at post-test and the covariate was the participants' measures of motor skills at pre-test. **Results** I1 and I2 groups showed a significant increase in both locomotor and object control skills compared with C group after PE program. I2 ability level was significant higher than I1 group. The improvement in locomotion skills was bigger than object manipulation those. The two abilities combined provide a Quotient of Gross-Motor Ability that was in the average at baseline in all groups and became high in I1 and I2 after PE program. **Discussion** The improvement of locomotor and object control skills in both intervention groups indicates that PE program positively affects the motor development of preschool children. We suppose that this is dependent on the duration of the intervention given the higher level of improvement showed by the I2. The difference in the ability levels between locomotor and object control skills might be associated with the maturation of nervous system and sensory-perceptual and motor experiences of children. Physiology

DEVELOPMENT OF A NEW PREDICTIVE MODEL ENABLING THE ASSESSMENT OF THE ANAEROBIC CAPACITY FROM A STANDARD AEROBIC EXERCISE STRESS TEST

EFRAT, L., TULER, T., SCHEINOWITZ, M.

Tel Aviv University

Graded exercise stress test (GXT) is a common and widely accepted method to assess the aerobic capacity and to predict maximal oxygen consumption and cardiorespiratory fitness. The first part of the GXT is aerobic while the last part includes the anaerobic component; meaning, utilization of ATP occurs mostly via anaerobic metabolism. The anaerobic capacity can be determined by the Wingate anaerobic test (WAnT) which is an intense test, performed on a bicycle against constant resistance. Our goal is to develop a new computational simulative predictive model, enable to predict the anaerobic capacity from a single GXT. We collected data from (n=52) subjects who underwent cardiopulmonary exercise stress test (CPET) and the WAnT. We looked at two cluster of features: 49 aerobic variables/features that can be extracted from the CPET and 12 features that can only be extracted from a GXT. We used the greedy heuristic algorithm model to test the best aerobic feature at each iteration and added it into the vector of selected features in order to predict peak and mean anaerobic power output obtained from the WAnT. The model was tested separately on the two clusters. All analyses were performed on MATLAB. When using features from CPET, we observed high peak power and mean power predictions [w] of $r=0.88$ and $r=0.87$, respectively. Lower predictions of peak power and mean power were observed when the anaerobic components were normalized by the body weight [w/kg] $r=0.74$ and $r=0.80$, respectively. Relatively lower peak power and mean power [w] predictions were also observed when using features that were obtained from the GXT, $r=0.68$ and $r=0.69$, respectively and when normalized to body weight [w/kg]: $r=0.69$ and $r=0.74$ for peak and mean power, respectively. Our results indicate that prediction of the anaerobic component is feasible by using advanced statistical prediction tools such as greedy heuristic algorithm. Good prediction was noted when using gas exchange data (CPET) ($r=0.87$), but lower prediction values when using GXT data ($r=0.68$). Thus, oxygen consumption and carbon dioxide production are significant factors during aerobic exercise stress test that can predict the anaerobic power output using a single exercise stress test. ROLE OF SODIUM-HYDROGEN EXCHANGER-1 IN THE EFFECTS OF EXERCISE ON INTERMITTENT HYPOXIA-INDUCED LEFT VENTRICULAR CARDIAC FIBROSIS

CHEN, T.I., YANG, K.T., TU, W.C.

Tzu Chi University

Background: Intermittent hypoxia (IH) of obstructive sleep apnoea (OSA) can increase oxidative stress levels that exacerbates the progression of cardiac fibrosis, leading to left ventricular dysfunction. Exercise can attenuate oxidative stress-induced myocardial sodium-hydrogen exchanger-1 (NHE-1) hyperactivation, preventing IH-induced left ventricular dysfunction. However, whether exercise attenuates cardiac fibrosis by reducing myocardial NHE-1 hyperactivity is still unclear. **Purpose:** To investigate the role of NHE-1 in exercise-mediated cardiac fibrosis attenuation in OSA patients using an animal model mimicking the IH of OSA. **Methods:** Eight-week-old male Sprague-Dawley rats were randomly assigned to room air (CON), IH, exercise (EXE) or IH combined with exercise (IHEXE) group. All groups were randomly assigned to subgroups receiving a vehicle or cariporide, NHE-1 inhibitor, at the beginning of 9th week. IH rats were raised without any intervention for the first 8 weeks and exposed to 14 days of IH (2–6% O₂, 2–5 s/75 s) for 8 h/day at the 9–10th week. EXE rats were subjected to an animal treadmill for 10 weeks (5 days/week, 60 min/day, 24–30 m/min, 2–10% grade) without IH exposure. IHEXE rats were made to exercise with IH at the 9–10th week. At the end of 10th week, the rats were sacrificed, and hearts were removed to determine the myocardial levels of fibrosis index (Masson's trichrome stain and Sirius red stain), lipid peroxidation, catalase activity and NHE-1 activation. **Results:** Compared with CON rats, IH caused an increased cardiac fibrosis, a decreased myocardial catalase activity and an increased lipid peroxidation and NHE-1 activation ($p < 0.05$, in all) that were abolished by cariporide. These changes were not

observed in EXE and IHEXE rats ($p > 0.05$, in all). Compared with IH rats, an increased anti-oxidant capacity and a decreased cardiac fibrosis, lipid peroxidation and NHE-1 activation were found in IHEXE rats ($p < 0.05$, in all). Conclusion: The 10-week exercise training caused inhibition of IH-induced myocardial NHE-1 hyperactivity, which can provide potent cardioprotective effects by attenuating IH-induced cardiac fibrosis. Thus, NHE-1 plays a critical role in the effects of exercise on IH-induced cardiac fibrosis.

EFFECT OF RAIN ON THERMAL RESPONSES AND ENERGY METABOLISM WHILE RUNNING AT HIGH INTENSITY IN COLD TEMPERATURES

ITO, R., SUZUKI, E., YAMASHITA, N., MATSUMOTO, T.

NIHON FUKUSHI UNIVERSITY

Introduction: Outdoor exercise such as marathons, soccer, and rugby often proceed under rainy conditions. We previously showed that esophageal temperature decreases and oxygen consumption and plasma lactate concentrations increase while moderately running in rain at 5°C. However, only a few studies have investigated physiological responses in humans during exercise in rainy conditions. To our knowledge, no reports to date have investigated human physiological responses in the cold, rainy conditions during high intensity exercise such as competitive outdoor sports. **Purpose:** The present study aimed to determine the effects of rain on physiological responses while running at 80%VO_{max} at 5°C. **Methods:** Seven healthy men [age, 21.7 ± 3.3 yr; height, 176.6 ± 8.5 cm; mass, 68.8 ± 7.1 kg; VO_{2max}, 62.3 ± 5.09 mL/kg/min; means ± SD] who were non-smokers and not currently under medication participated in this study. They rested for 10 min and then exercised on a treadmill at 80%VO_{max} intensity for 60 min in the presence (RAIN) or absence (CON) of rain at 5°C. A headwind equal to running speed was blown during both trials, which were randomly assigned and balanced for order. **Results:** Rectal temperature was significantly lower in RAIN than that in CON at 10, 40, 50, and 60 min ($p < 0.05$). Weighted mean skin temperature was significantly lower in RAIN than that in CON during exercise ($p < 0.05$). Thermal sensation was significantly lower in RAIN than in CON from 30 to 60 min ($p < 0.05$). Oxygen consumption, heart rate, and rating of perceived exertion were significantly higher in RAIN than in CON at 50 and 60 min ($p < 0.05$). Plasma lactate was significantly higher in RAIN than in CON from 40 to 60 min and plasma norepinephrine was significantly higher in RAIN than that in CON at 10, 40, 50, and 60 min (both $p < 0.05$). Plasma glucose, plasma epinephrine, serum triglycerides, serum free fatty acids, and the respiratory exchange ratio did not significantly differ between RAIN and CON. **Discussion:** The lower rectal temperature and higher plasma norepinephrine at 10 min in RAIN indicate that rain increases heat loss during the early phase of exercise in the cold. Thereafter, heat production increases through high-intensity exercise and transiently suppressed cold stress. However, a wet area that increased over time in RAIN intensified the loss of body heat and then energy expenditure and plasma lactate increased more in RAIN than in CON due to cold stress. **Conclusion:** Rain intensifies body heat loss and increases energy expenditure while running at high intensity at 5°C.

EFFECTS OF COLD SHOWERS ON PHYSIOLOGICAL RESPONSES AFTER EXERCISE IN HOT ENVIRONMENT

AJJIMAPORN, A., WIDJAJA, W., SIRIKUN, P.

Sports Science and Technology

Introduction While CWI is the most popular recovery method in the literature worldwide, it has been reported to have adverse effects on cardiovascular response¹ and thermal comfort sensation² especially in those athletes who are susceptible to cold temperature. Taking a shower is an activity that millions of people make a part of their daily routine. Unfortunately, the information of cold showers for recovery purpose has yet to be identified for individuals in the tropical climate of Southeast Asia. The present study investigated recovery effects of cold water showers on heart rate (HR), core temperature (Tc), cortisol and thermal comfort scale (TCS) after exercise in hot environment. **Methods** Nine healthy males (mean ± SD: age 21±1 yr; body mass index = 22.9±1.8 kg.m⁻², % fat mass = 16.6±6.1, V' O_{2peak} = 32.6± 4.1 mL.kg⁻¹.min⁻¹[mean + S.D.]) randomly underwent two interventions following an exercise period of 45 minutes in a hot environment (35 °C room temperature, 40-60% relative humidity) on a cycle ergometer at 65% of their peak oxygen uptake. The two interventions compared a 15 °C water showers (CWS) with sitting in a 25 °C room (SIT25) for 15 min after exercise. After the 15 min intervention, measures of Tc and HR were recorded at 30 min, 1h, and 2h; salivary cortisol levels determined at 1h and 2h; and the thermal comfort scale (TCS) recorded at the end of intervention. **Results** The results showed that the % change of HR had decreased significantly faster with a CWS than with a SIT25 at the first 30 min of recovery period ($p < 0.05$), but no differences were observed for %change of Tc as well as salivary cortisol levels at all the time points of recovery period. TCS was lower in SIT25 (+2; Just comfortable) than CWS (+4; Very comfortable) after 15 min of intervention. **Discussion** The finding of significant recovery benefits for CWS over SIT25 on HR and TCS demonstrates that taking a cold shower can be a good choice for facilitating HR recovery after high intensity performance in a hot environment. **References** Tipton MJ (2015). Physiological response to cold water immersion and submersion:from research to protection. In: Taber, Michael, ed. EFFECTS OF LEARNING TASKS ON HEART RATE VARIABILITY

PERINI, R.1, CAPOGROSSO, M.1, BORTOLETTO, M.2, FERTONANI, A.2, MINIUSI, C.1,2

University of Brescia

Introduction Cardiac autonomic activity has been extensively evaluated by analysis of Heart Rate Variability (HRV) in many physiological conditions, including the execution of cognitive tasks. It has been shown that the higher the mental load the larger the effect on HRV, vagal indices especially decreasing more in executive than in non-executive tasks. The influence of different cognitive functions on autonomic modulation of HR have not however clearly defined. Our aim was to evaluate the effect of learning tasks, specifically in motor and visual domain, on HRV. **Methods** Thirty healthy males (age: 23±2 yrs, mean±SD) were administered a motor task (MT) and a visual task in two separate sessions. The MT consisted of performing a sequence of 64 abduction movements with the left thumb as fast as possible. The visual task was an orientation discrimination task (ODT), in which the subject had to decide whether the presented stimulus was tilted clockwise or counter-clockwise relative to the previously presented stimulus. Heart Rate (HR) was continuously recorded (Polar S-810) before (6-8 minutes, while quiet sitting; control, ctrl) and during the execution of the tasks (each lasting about 5 minutes). HRV was analyzed in time and frequency domains and by Poincaré plot. **Results** R-R interval was 819.6±133.4 ms in ctrl and did not change during both MT and ODT (907±172 ms and 888±190 ms, respectively). SDNN decreased from ctrl value (83±31 ms) by about 25% in both tasks ($p < 0.05$), whereas no change was found for rMSSD (overall mean 63±53 ms). SD1 showed no modification during the two tasks (44.78±37.2 ms). In contrast SD2 decreased from 107.9±34.9 ms in ctrl to similar values in MT and ODT, i.e. 70.9±39 ms. LF/HF ratio was

5.15 ± 4.2 in ctrl and dropped to 1.7 ± 1.0 during MT and to 2.2 ± 3.5 during ODT ($p > 0.05$ between tasks). Discussion The execution of both MT and ODT was associated with unchanged R-R interval, i.e. HR was stable compared to control, but with different values of HRV. During the two tasks, indices of slow fluctuations of HR (SDNN and SD2) were significantly lower than in control, while markers of rapid fluctuations (rMSSD and SD1) remained almost constant. This would suggest a selective effect of learning on rhythmic autonomic modulation of HR. The decreased LF/HF ratio found during both tasks would indicate a shift in the autonomic interaction toward a vagal dominance, possibly as an effect of the demand of learning process. renza.perini@unibs.it

THE EFFECT OF PRACTICALLY APPLIED BLOOD FLOW RESTRICTION OF THE LOWER LIMBS DURING HIGH INTENSITY CYCLING EXERCISE ON CIRCULATING GROWTH HORMONE

STOREY, A., MCDONNELL, D., BOWDEN, S.

Waterford Institute of Technology

Introduction Growth hormone (GH), a key regulator of protein synthesis, is secreted in response to resistance and aerobic exercise in an intensity-dependent fashion. Blood flow restriction (BFR) during low intensity resistance and aerobic exercise has been demonstrated to potentiate GH secretion (Abe, Kearns, & Sato, 2006). The objective of this study was therefore to investigate whether the GH response to high-intensity exercise (HIE) is further potentiated by BFR. Methods Eight young healthy males (age 22.5 ± 2.1 y, height 177 ± 5.9 cm, weight 76 ± 11.0 kg) completed two trials consisting of 3×30 s maximum sprints on a cycle ergometer with 4min of active recovery between sprints. Trials were performed in random order with (RBF) or without (CON) elastic wraps applied around the proximal thigh with a compression equivalent to a subjective rating of seven on the Pain Visual Analog Scale. Venous blood samples collected before and 20min post-exercise were analysed for GH by ELISA (Leinco Technologies Inc., Missouri) and capillary blood lactate concentration (Blac) was determined before and immediately post-exercise. Cycling power and pre-to-post changes in GH and Blac were compared between trials using a paired t-test. Results No differences were observed between trials in peak power (CON = 1192 ± 31.5 W; RBF = 1153 ± 47.7 W; $p = 0.30$), mean power (CON = 517 ± 43.5 W; RBF = 517 ± 45.1 W; $p = 0.50$), Blac (CON = 12.2 ± 0.25 mmol/L; RBF = 12.1 ± 0.17 mmol/L; $p = 0.60$) or GH-response (CON = 32.2 ± 5.87 ng/ml; RBF = 32.1 ± 6.36 ng/ml; $p=0.98$). Discussion Restricted blood flow induced muscle hypoxia resulting in accumulation of metabolic products and secretion of anabolic hormones is the primary postulated mechanism underlying adaptations associated with RBF during low intensity exercise (Pearson & Hussain, 2015). However this study showed no effect of RBF during HIE on exercise performance, Blac or GH. Perhaps the time course of oxygen uptake and the heavy dependence on anaerobic metabolism during non-RBF HIE renders the muscles in a similar state to RBF HIE, therefore resulting in little additional effect of RBF. A review on the mechanisms of blood-flow restriction resistance training-induced muscle hypertrophy. Sports Medicine (Auckland, N.Z.), 45(2), 187–200. doi:10.1007/s40279-014-0264-9

ACUTE PHYSIOLOGICAL RESPONSES IN MUSICIANS DURING A PUBLIC CONCERT AND REHEARSAL: A PILOT STUDY

KORINEK, M., TSCHAKERT, G., HOFMANN, P.

University of Graz, Austria, Institute of Sports Science

Introduction Playing music is a demanding activity, but up to now only few studies evaluated the physiological responses in musicians (1, 2). The aim of this pilot study was, therefore, to analyse the metabolic and cardiorespiratory responses during a public concert and a rehearsal in Rock'n'Roll band members. Methods 4 male musicians (all of them members of a Rock'n'Roll Band; age: 26 ± 3 years old; height: 180 ± 10 cm; weight: 75 ± 8 kg; VO_{2max}: 51.2 ± 10.3 ml/min/kg) were tested while playing their instruments (drums, double bass, e-guitar, accordion). Heart rate (HR) was measured during a public concert and a rehearsal. The blood lactate concentration (La) was measured during the rehearsal at the end of each song. The determined data were compared to the values at the first (LTP1) and second (LTP2) lactate turn point detected during a preliminary maximal incremental exercise test (IET) performed on a cycle ergometer (3). Results In absolute terms and expressed as % of the according values at LTP2, playing drums, double bass, e-guitar, and accordion induced the following acute responses during the rehearsal: HRmean: 142, 151, 110, 103 b/min (88, 92, 73, 64 % of HR at LTP2); Lamean: 4.7, 4.0, 2.7, 2.4 mmol/l; HRpeak: 180, 177, 132, 126 b/min (112, 108, 87, 78 % of HR at LTP2); Lapeak: 6.1, 5.6, 4.2, 2.8 mmol/l. During the public concert, values were found at: HRmean: 162, 165, 142, 111 b/min (101, 101, 94, 69 % of HR at LTP2); HRpeak: 175, 182, 162, 148 b/min (109, 111, 107, 92 % of HR at LTP2). Discussion The level of physiological strain depends on the style of the song, the intensity of movement which varies according to the certain instrument and extra activities e.g. vocals. Rock'n'Roll music was shown to be a physiologically demanding activity inducing acute physiological responses which were mostly higher compared to LTP1 and partly higher compared to LTP2 from IET (1, 2). Double bass playing combined with singing and the higher amount of movement in drumming are expected to be responsible for the increased physiological responses in these two instruments. The need for an appropriate endurance capacity for musicians to sustain long lasting concerts is obvious. Due to the received data, playing music is supposed to generate aerobic effects and regular exercise training should be suggested to maintain quality during concerts. Playing this kind of music might be a possible alternative to sportive activities especially for inactive people. HAEMATOLOGICAL PARAMETERS IN MIDDLE-AGED AMATEUR FEMALE RUNNERS FOLLOWING TWO DIFFERENT SCHEDULE TRAINING FOR A HALF-MARATHON RUN

TORRELLA, J.R., BONET, J.B., ALAMO, J., MANCERA, E.M., RAMOS, D.M., RIZO, D., PAGÈS, T., VISCOR, G., MAGALHÃES, J., JAVIERRE, C.

Universitat de Barcelona

INTRODUCTION Amateur running for distances from 10 to 20 km is being increasingly popular. Since the half-marathon is a common challenge for amateur runners, several training schedules are available, even for master sport practitioners (1). Most are extensive schedules involving high training volumes in km/wk. We designed an intensive schedule with higher loads and lower running volumes. Our objective was to evaluate the changes in haematological parameters before and after two different training schedules. METHODS Twenty-two women (39 ± 6 years) followed an extensive (EX) or intensive (IN) schedule of 3 sessions/wk during 12 wk. EX group trained a mean of 31 ± 4 km/wk at an intensity below 80% VO_{2max}. IN group run 25 ± 5 km/wk (80-100% VO_{2max}) combined with uphill running

and resistance training circuits. Blood samples were obtained before (S1) and after (S2) both training programmes and after 20h of a half-marathon run (S3). One way ANOVA with repeated measures allowed to compare S1-S2-S3 within schedules whereas a Student's t test was used to contrast the two programs. RESULTS Haemoglobin concentration (Hb) and RBC count showed a non-significant decrease in both groups, with a greater decrease in EX (Hb, 2.3%; RBC, 2.1%) than in IN (Hb, 0.8%; RBC, 0.6%). Haematimetric indices related to Hb concentration showed significant ($P<0.001$) decreases from S1 to S2 in EX but not in IN, whilst MCV increased in both groups ($P<0.05$) from S1 to S3. Haematocrit (Hc) increased in EX (S1=40.0%, S2=42.3%; $P<0.001$) but remained almost unchanged in IN (S1=39.3%, S2=39.5%), resulting in higher significant ($P<0.05$) values in S2 for EX group. From S2 to S3, WBC counts increased (26%, $P<0.05$) only in IN, whilst platelets decreased in both groups (EX, 13%; IN, 17%; $P<0.01$). DISCUSSION A 12-wk schedule of EX training (S2) caused a greater reduction in total and mean Hb concentrations, and in RBC count as compared to IN training, maybe due to a greater haemolysis provoked by the higher volume of running. The greater Hc in EX group indicates that this schedule could elicit a greater aerobic capacity. After 20h of the half-marathon (S3), macrocytosis of RBCs reflect an elevated RBC turnover response to intense exercise (2) and the lower platelet count a result of a shear-induced platelet adhesion and aggregation (3). The half-marathon also induced a higher increase in WBCs in IN than in EX, which may be related with different inflammatory and oxidative stress responses provoked by the different training schedules. INHIBITION OF ERK 1/2 PHOSPHORYLATION DOES NOT SUPPRESS EXERCISE-INDUCED S6K1 PHOSPHORYLATION AND MUSCLE PROTEIN SYNTHESIS

ARATA, T.1, RIKI, O.2, DAISUKE, T.3, TAKAHIRO, M.3, SHIGETO, T.1, KOICHI, N.1

1:Nippon Sport Science University, 2:Nagoya Institute of Technology, 3, The University of Tokyo

Introduction Muscle contractions that generate large amounts of force, like resistance exercise, rapidly increase muscle protein synthesis (MPS) and subsequently cause hypertrophy. Exercise-induced increase in MPS has been reported to be regulated by multiple signaling pathways, of which the mTORC1 signaling pathway is a pivotal regulator. The MAPK signaling pathway is considered another regulator of the increase in MPS. The mTORC1 and MAPK pathways are coordinated; although activated mTORC1 phosphorylates the T389 site in S6K1, the phosphorylation of T421/S424 sites in S6K1 through the MAPK pathway and subsequent conformational change in S6K1 are necessary. Although ERK 1/2, a molecule in the MAPK signaling pathway, is known to phosphorylate T421/S424 in S6K1, only one study has reported the impact of the inhibition of ERK 1/2 phosphorylation on the exercise-induced increase in MPS in vivo. Thus, we examined whether inhibition of ERK 1/2 phosphorylation affects the exercise-induced increase in MPS. Methods Rats were divided into two groups (n=5 in each group) and were intraperitoneally injected with 10 mg·kg⁻¹·day⁻¹ of either vehicle (40% DMSO in PBS, vehicle group) or MEK inhibitor (U0126, U0126 group) every other day for 1 week. For exercise, an electrical stimulation model from our previous study was modified and employed (Tsutaki et al., 2013). Briefly, rats were anesthetized with 2.5% isoflurane and the right leg was isometrically contracted for 40 contractions by electrical stimulation at 100 Hz. Rats were dissected at 1 h post exercise. The left leg of the rats served as the unexercised leg. Western blotting was used to analyze MPS and signal proteins. In statistical analyses, the paired t-test was used for MPS and two-way ANOVA was used for signal proteins. Results We found that ERK 1/2 phosphorylation was significantly lower in the U0126 group than in the vehicle group, irrespective of exercise. In the same group, ERK 1/2 phosphorylation in exercised muscle was significantly higher than that in unexercised muscle. Increased MPS and phosphorylation of T389 and T421/S424 of S6K1 in exercised muscle were observed in both the vehicle and U0126 groups. Discussion The above results suggest that inhibition of ERK 1/2 phosphorylation does not suppress exercise-induced MPS and phosphorylation of S6K1. Other signaling molecules may be involved in the modulation of mTORC1 signaling in the exercise-induced increase in MPS. References Tsutaki A, Ogasawara R, Kobayashi K, Lee K, Kouzaki K, Nakazato K. CARDIORESPIRATORY RESPONSES TO GRADUAL AND ACUTE HYPOXIA DURING CONSTANT LOAD EXERCISE

ISHIDA, K.1, YAMAUCHI, K.1, SATO, K.2, KATAYAMA, K.1

1: Nagoya University (Nagoya, Japan), 2: Japan Women's College of Physical Education (Tokyo, Japan)

Introduction Acute mountain sickness (AMS) is caused by high altitude hypoxia, and can be fatal. During climbing to high altitude, inspired oxygen content gradually becomes lower. Simulating this situation in a laboratory at sea level may help us predict who is more likely to suffer from AMS before climbing to high altitude, thereby reducing individuals' risk to develop AMS. We are now able to generate a gradually increasing hypoxic stimulus by controlling a gas generator. The purpose of this study was to confirm the validity of this method for screening potential AMS. Methods Sixteen collegiate subjects performed constant load (40% VO_{2peak}) cycling exercise for 5 min at room air, and then continued to exercise for 15 min while inhaling a hypoxic gas mixture. Gradual hypoxia (GR) was conducted by reducing inspired oxygen concentration (FIO₂) linearly from 20.9% (sea level) to 11.8% (4500m altitude) at the rate of 1% / min. Acute hypoxia (AC) was archived by a sudden decrease in oxygen to FIO₂=11.8%. Each test consisted of two different end tidal CO₂ (PETCO₂) conditions: poikilocapnea (PO) simulating a climbing situation, and isocapnea (IS) induced by adding CO₂ to the inspired gas mixture in order to clarify the influence of hypoxia per se. Four hypoxic exercise conditions were studied in total. The same exercise was also performed in room air normoxic conditions (NR). The gradual hypoxia test was also performed in resting poikilocapnic conditions (RS). Results Hypoxia increased minute ventilation (VE) exponentially without delay in AC, while it increased VE in sigmoidal fashion with some delay in GR, and thereafter both reached steady state. The steady state VE in GR was a little smaller than that in AC but there was no significant difference. The steady state VE in PO was significantly smaller than that in IS. The arterial oxygen saturation (SpO₂) change mirrored VE change, but the magnitude of decrease in IS was smaller than that in PO. Heart rate showed a similar change as VE, independently of PETCO₂. The rate of perceived exertion (RPE) estimated by Borg's scale in GR increased mildly as compared with that in AC during early stage of hypoxic exercise. Discussion Physical and mental stress seems milder during GR than that during AC so that GR can safely simulate climbing to high altitude. However, these cardiorespiratory responses had some intra-subject differences. Detailed investigation of these differences between climbers who have or have not experienced AMS may afford prediction of AMS. Further investigation is required. Conclusion Our results suggest that gradual hypoxia during exercise could successfully simulate climbing to high altitude. Contact E-mail: ishida@htc.nagoya-u.ac.jp

THE ANTI-PHASIC REONSE OF BRACHIAL ARTERY BLOOD FLOW TO SINUSOIDAL WORK RATE LEG EXERCISE

FUKUBA, Y.I., MIURA, K.I., EGUCHI, K.I., ENDO, M.Y.I., KASHIMA, H.I., HAYASHI, N.2, FUKUOKA, Y.3, KOGA, S.4

1: Prefectural University of Hiroshima (Hiroshima), 2: Tokyo Institute of Technology (Tokyo), 3: Doshisha University (Kyoto), 4: Kobe Design University (Kobe)

Introduction It has been classically accepted that the blood flow (BF) to non-active muscles decreased during dynamic exercise (i.e., BF in arm muscles during leg cycling). The recent studies (e.g., Simmons et al., 2011), however, showed that, during leg cycling, the BF in brachial artery (BA) did not reduce, rather increased with work rate (WR). To clarify such discrepancy, we observed the control of BF in BA during leg cycle exercise with sinusoidal WR forcing. Methods Nine healthy young male subjects exercised using an electromagnetically braked ergometer which is able to control the sec-by-sec WR via transport cable by external PC software. The subjects were performed for 30 min at a constant WR (the mean of sinusoidal WR forcing) followed by 16-min sinusoidal WR exercises of 4-min period (i.e. 4 times repetitions) where WRs were fluctuated in the range of 20 W to 50 % of peakVO₂. During the protocol, we measured pulmonary gas exchange [breath-by-breath], heart rate (HR) and mean arterial blood pressure (MAP) [Photoplethysmograph], blood velocity (BV) and cross sectional area of BA [Ultrasound Pulsed-Doppler], and forearm skin BF (SBF) [Laser Doppler] and sweating rate (SR) [Capacitance Hygrometry]. The sec-by-sec variables were superimposed every three cycles during 2nd to 4th sinusoidal exercises to fit the sinusoidal model which was parameterized by mean level (M), amplitude (A), and phase delay. Results and Discussion Almost all responses were well described by the sinusoidal model, e.g., the conventional indicators of goodness of fit (r^2) for VO₂, Cardiac Output, BF in BA, and SBF (forearm) were averaged as 0.868, 0.801, 0.533, and 0.682, respectively. The phase delays of variables regarding pulmonary gas exchange and central circulation followed sinusoidal WR fluctuation with approximately 30-60 ° which were similar to those in the previous studies (e.g., Casaburi et al., 1977). Contrarily, the response of BF in BA showed the anti-phase (175 ± 28 °) and large amplitude (A/M: 30 ± 9 %), and did not reflect the phase delays of skin BF and SR. In conclusion, the control of non-active limb circulatory control is substantially different to the main gas exchange and circulatory control of the O₂-delivery to active muscles. EFFECT OF RESISTANCE TRAINING ON INFLAMMATION MARKERS AND ANTI-OXIDANT ENZYME IN AORTA OF OBESERATS

KIM, H., LEE, J., PARK, S.

Konkuk University

Introduction: Obese individuals have excess abdominal visceral fat, which is a better predictor of cardiovascular and metabolic risk than total body fat alone and is also linked to altered vascular function. There is a lack of research in the investigation on the effects of resistance training on obesity resulting in increase of inflammatory response and antioxidant enzymes. Therefore, we investigated the effect of resistance exercise on the inflammatory makers (including NF-κB, TNF-α, COX-2) and Cu-Mn SOD expression in aorta of type 2 diabetic rats. **Methods:** Six week-old male ZDF (Zucker diabetic fatty) and ZLC (Zucker lean control) rats were randomly divided into 3 groups: sedentary ZLC (ZLC-Con), sedentary ZDF (ZDF-Con), and exercised ZDF (ZDF-Ex). ZDF-Ex rats were trained (once every 3 days for 8 weeks) to climb a 1.1-m vertical (80° incline) ladder with weight secured to their tail for progressive resistance exercise. The expressions of inflammatory markers (including NF-κB, TNF-α, Cox-2) and SOD were evaluated using western blotting. **Results:** NF-κB expression was significant decreased ($p < 0.05$) in ZDF-Ex group compared to ZDF-Con group. In TNF-α expression, we there were significant decreased ($p < 0.01$) in ZDF-Ex group compared to ZDF-Con group. In similar trend with NF-κB expression, Cox-2 expression was significantly decreased in ZDF-Ex compared to ZDF-Con. In Cu-Mn SOD expression, there was no difference between ZLC-Con and ZDFCon group, however, significant increases ($p < 0.01$) of Cu-Mn SOD was found in ZDF-Ex compared to ZDF-Con group. **Discussion:** Chronic vascular inflammation is the fundamental mechanism of vascular diseases associated with variety of risk factors, contributing to pathogenesis of atherosclerosis and plaque rupture, leading to acute coronary syndrome [1]. Oxidative stress is characterized with the excessive production of oxidant molecules that overwhelm the anti-oxidant defense systems, resulting in oxidative damage [2]. Based on the previous reports and our results, resistance exercise training might be efficient intervention for the modulation of vascular inflammation and oxidative stress in obesity. **References** [1] Lonn ME, Dennis JM, Stocker R. THE EXTRA FAT MASS AND BODY FLUID VOLUME OF THE RUGBY PLAYER ATTENUATE BY A CAMP

TAKASHINA, T., KUSHI, H., FUKADA, K., AMANO, K., YOSHIDA, A., KATO, H.

Nihon University

[Introduction] Many competition athletes often participate in a camp to update their self-record and to win in a game. In this study, we investigated a camp of a rugby club and examined the change in body composition of competition athletes before and after the camp. **[Methods]** The subjects were 15 university students who were members of rugby football clubs. Using bioelectrical impedance analysis, we calculated their body composition before and after the camp. **[Results]** The weight [pre (90.0 ± 2.5 kg), post (84.8 ± 2.6 kg)] ($p < 0.01$), fat mass [pre (18.3 ± 1.7 kg), post (14.9 ± 1.5 kg)] ($p < 0.01$), body fat percentage [pre ($20.3 \pm 1.5\%$), post ($17.3 \pm 1.4\%$)] ($p < 0.01$), and body fluid volume [pre (51.6 ± 1.2 L), post (50.9 ± 1.3 L)] ($p < 0.05$) showed a significantly low value after the camp in comparison with before the camp. Skeletal muscle mass [pre (40.6 ± 1.0 kg), post (40.4 ± 1.0 kg)] showed no significant difference. However, Skeletal muscle percentage [pre ($45.8 \pm 0.9\%$), post ($47.8 \pm 0.8\%$)] and extracellular water [pre (0.21 ± 0.003 L/kg), post (0.22 ± 0.003 L/kg)] ($p < 0.01$) showed a significantly high value after the camp in comparison with before camp. **[Conclusions]** This study demonstrated a decrease in weight and body fat percentage and an increase in skeletal muscle percentage in the subjects after the camp. However, these changes were not due to an increase in the quantity of muscle, but were due to a decrease in extra fat mass and body fluid volume.

THE CURRENT STATE OF THE WATER INTAKE OF SPECTATORS AT A HIGH SCHOOL BASEBALL IN JAPAN

IIDA, T., SEKI, K., TAKAGI, Y., NISHIMURA, K., MIYASAKA, Y.

Shujitsu University

Introduction Not only sports players but also spectators have the possibility of heat stroke. However, a field survey report about thermo physiological response of sports spectators in a hot environment isn't found. In Japan, the whole country's Senior High School baseball summer championship is the most popular sports event under education. Therefore, this event has many spectators that include students, children and elderly. On the other hand, the heat stroke onset of spectators at this event is actualized. So, the purpose of this study was to show clearly the current state of water intake of spectators at a high school baseball. **Methods** We carried out an investigation in spring and summer. Seven healthy young men (23.0 ± 4.5 yrs, 172.1 ± 7.2 cm, 72.0 ± 8.0 kg) in spring investigation and ten healthy young men (21.1 ± 0.6 yrs, 169.9 ± 4.0 cm, 63.4 ± 7.1 kg) in summer volunteered for this study. These investigations were condition that the subjects could drink mineral water freely during watching one game of a high school baseball. The measurement contents were water intake, sweat loss, weight loss, temperature, humidity and WBGT. **Results and Discussion** The environment condition of spring was temperature: $14.8 \pm 0.6^\circ\text{C}$, humidity: $23.3 \pm 0.4\%$ and WBGT: $10.3 \pm 0.4^\circ\text{C}$. That of summer was temperature: $36.2 \pm 0.9^\circ\text{C}$, humidity: $50.2 \pm 4.2\%$ and WBGT: $34.6 \pm 0.7^\circ\text{C}$. In the spring condition, water intake was 35.7 ± 37.8 ml, body weight loss was 0.2 ± 0.3 kg, and sweat loss was 0.3 ± 0.3 kg. In the summer condition, water intake was 370.5 ± 132.4 ml, body weight loss was 0.5 ± 0.3 kg, and sweat loss was 0.9 ± 0.3 kg. All measurement contents in the summer condition were significantly higher than that in the spring condition ($P < 0.05$). In summer, though the water intake increased, the weight loss increased, too. This result showed that the spectators at high school summer baseball lacks water intake which depended on thirst rating. We concluded that there is possibility that heat stroke onset even if it is the watching sport that is almost rest condition. It's necessary to be careful when watching Tokyo Olympic Games, too.

THE EFFECT OF TAPING ON PAIN-RELATED SOMATOSENSORY EVOKED POTENTIALS

YAMASHIRO, K., SATO, D., ONISHI, H., NAKAZAWA, S., MARUYAMA, A.

Niigata University of health and welfare

Introduction Taping is widely used in sports medicine to prevent injury, protect affected sites post injury and relieve pain. However, it is not clear whether taping affects the perception of noxious stimulation because in previous studies, it was difficult to selectively activate A δ fibers. A recently developed, useful, new tool named intra-epidermal electrical stimulation (IES) can preferentially activate A δ fibers. We aimed to clarify the effect of taping on pain-related somatosensory evoked potentials (pSEPs) using IES. **Methods** We recorded pSEPs following IES of the right medial forearm in seven healthy volunteers. pSEPs were recorded from 9 electrodes on the scalp under control, elastic-taping and white-taping conditions. Under the control condition, subjects relaxed on a comfortable reclining seat without taping, whereas under the taping conditions, they were subjected to taping along the forearm with tension (elastic-taping) and without tension (white-taping). Subjects were asked to assign a visual analog scale (VAS) score after each session. **Results** The peak amplitudes of N2-P2 were significantly lower under the elastic-taping and white-taping conditions than those under the control condition, and VAS score in the elastic-taping condition was the lowest among three conditions. Moreover, there was a significant positive correlation between the amplitude of N2-P2 and VAS. **Discussions** We revealed that taping along the forearm decreased pSEPs and subjective pain perception under the white-taping and elastic-taping conditions. The underlying mechanism of pain relief was the distraction effect in both taping conditions. In addition, elastic taping with tension changes various afferent inputs from the muscle spindles and the skin, and this might more effectively decrease the pain perception than that achieved under the white-taping condition.

PHYSIOLOGICAL STRAIN IN HELICOPTER PILOTS IN EMERGENCY MEDICAL SERVICES

RINNERHOFER, S.1, WULTSCH, G.2,3, FASCHING, P.1, HOFMANN, P.1

University of Graz

1: Institute of Sports Science, Exercise Physiology, Training & Training Therapy Research Group, University of Graz; 2: Medical University Graz; 3: AMEZ GRAZ, Austria **Introduction** Pilots in helicopter-based emergency medical services operate up to 16 h of duty for 7 consecutive days. This kind of work represents mainly heavy peak psychological strain with permanent operational readiness which is not hard work in a traditional sense. But acute and chronic stress can lead to depression, metabolic syndrome, myocardial infarction with a higher probability (Öhlin et al. 2004; Hamer et al., 2012). Samel et al. (2004) showed that stress hormones in emergency helicopter pilots increased up to 80% due to a monitoring day. Aim of the study was to determine physical strain and stress parameters (HRV, stress hormones) in emergency medical services pilots in Austria. **Methods** The study included 21 male (age: 44.5 ± 6.2 yrs) pilots of emergency medical services in Austria. Cycle ergometer test to determine exercise performance was performed in 12 pilots. Thresholds for blood lactate and gas exchanges variables were determined by linear regression break point analysis. Heart rate (HR) and HR variability (HRV) were measured during 24 hours including a whole work-shift (A) (13.25 ± 1.68 h), different phases during worktime (e.g. in flight, in alerting time) and was compared to a leisure time day off (F). 24 hour cortisol, adrenalin, noradrenalin and dopamine were measured in urine samples. Every three hours cortisol was measured from saliva samples. Results Pilots had a maximal oxygen uptake of 3.202 ± 0.367 l/min and HR at the first lactate turn point (LTP1), a marker of heavy work occupational work, was 116.3 ± 9.4 b/min. Mean HR during work time was significantly different from the day off (A: 75.7 ± 9.0 b/min; F: 70.6 ± 9.1 b/min). HRmax during different phases in work reached 156 ± 14.3 b/min. RMSSD during worktime was 30% lower than in F. Significant differences were also found for cortisol, adrenalin, noradrenalin and dopamine being 50 to 70 % higher in worktime. Cortisol in saliva was not significantly different between work and leisure time. **Discussion** Considerably increased stress parameters were found in pilots in Helicopter-based emergency medical services which was similar to the study of Samel et al. (2004). It has to be questioned which health related consequences this kind of psychological strain combined with long duty cycles of up to 12 hours and longer could cause. In future long term studies are needed to investigate possible health consequences. **References** Samel A, Vejvoda M, Maass H. Aviat Space Environ Med 2004; 75:935–40. TREADMILL RUNNING AMELIORATES MUSCULAR DYSFUNCTION IN LACTATIONAL DEHP-EXPOSED RATS

WANG, D.C.

Kaohsiung Medical University

Introduction Di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, is regarded as an endocrine disruptor to exert adverse effects on the myogenic differentiation (Chen et al., 2013). Exercise has been proposed as a strategy for ameliorating a range of muscular disorders by strengthening strength and increasing resistance to fatigue (Alexanderson et al., 2014). In this study, we conducted an experiment regarding the effects of treadmill running on muscle strength in young adult male rats receiving postnatal DEHP exposure. Method Rat dams were fed with vehicle or DEHP (10 mg/kg per day) during lactation. After weaning, the male offspring were divided into 4 groups: control (C), DEHP (D), exercised control (Cex), and exercised DEHP (Dex). Rats were trained to exercise on a treadmill for 5 weeks from postnatal day 22 to 60 and then the muscle strength was measured by force transducer. The function of gastrocnemius was evaluated by measuring the plasma levels of insulin-like growth factor (IGF-1), the expressions of myosin heavy chain (MHC), peroxisome proliferator activated receptor gamma coactivator-1 α (PGC1 α), and mammalian target of rapamycin (mTOR). Result The results demonstrate that the lactational DEHP-exposed rats exhibited decreased muscle strength. Decreased IGF-1, MHC-I, PGC1 α , and phosphorylated mTOR (p-mTOR) were observed in the lactational DEHP-exposed animals. Importantly, in the lactational DEHP-exposed animals, treadmill running during childhood-adolescence restored the muscle strength by normalizing the expressions of MHC-I, PGC1 α , and p-mTOR. Discussion Lactational DEHP exposure may impair the muscle strength and the muscular development. Meanwhile, treadmill running during the childhood-adolescence can restore the muscle strength by improving the expressions of MHC-I, PGC1 α , and p-mTOR in DEHP-exposed young male rats. These findings suggest that treadmill running may provide beneficial effects on ameliorating the dysfunction of muscle in the lactational DEHP-exposed adolescent male rats. References 1. TREADMILL RUNNING PROTECTS THE SPATIAL LEARNING IN LACTATIONAL DEHP-EXPOSED YOUNG RATS

LEE, Y.C.

Tainan University of Technology

Introduction Aerobic exercise can improve learning and memory by enhancing the expression of brain-derived neurotrophic factor (BDNF) (Singh and Staines, 2015). Early life exposure to di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, may impair the expression of BDNF in rats (Smith and Holahan, 2014). In this study, we investigated the effects of treadmill running on the expression of BDNF and the performance of spatial learning in young rats that were exposed to DEHP during their lactational period. Method Rat dams were fed with vehicle or DEHP (10 mg/kg per day) during lactation. After weaning, the male offspring were divided into 4 groups: control (C), DEHP (D), exercised control (Cex), and exercised DEHP (Dex). Rats were trained to exercise on a treadmill for 5 weeks from postnatal day 22 to 60 and then the spatial learning was examined by Morris water maze. The functions of brain were evaluated by measuring the plasma levels of brain-derived neurotrophic factor (BDNF), hippocampal expressions of activity-regulated cytoskeleton-associated protein (Arc), phosphorylated cAMP response element-binding protein (p-CREB) and synaptophysin. Result Spatial learning of Morris water maze was impaired in the D group. Expressions of BDNF, Arc, and p-CREB were significantly decreased in the D group compared to the C group, however, there was no difference in the expression of synaptophysin between groups. After 5 weeks of treadmill running, spatial learning was improved in Dex group compared to D group. Biochemical evidence showed that expressions of BDNF, Arc, and p-CREB were increased in Dex group compared to D group. Discussion Lactational DEHP exposure may impair the spatial learning and the learning-induced expressions of BDNF, Arc, and p-CREB in the hippocampus, suggesting an impairment of synaptic plasticity in the DEHP-exposed rats. Meanwhile, aerobic exercise during the childhood-adolescence can restore the synaptic plasticity by improving the learning-induced expressions of BDNF, Arc, and p-CREB in the hippocampus of DEHP-exposed young male rats. ACUTE IMPACT OF COFFEE INTAKE ON CEREBRAL BLOOD FLOW AND ARTERIAL STIFFNESS IN THE SYSTEMIC CIRCULATION

WASHIO, T., SASAKI, H., OGOH, S.

toyo university

Introduction Previous research suggests an acute increase in risk of ischemic stroke in the hour after coffee intake (Mostofsky et al., 2010), while caffeine increases acutely arterial stiffness as well as blood pressure and peripheral resistance (Mahmud et al., 2001). An increase in brachial-ankle pulse wave velocity (baPWV) elevated pulsatility index (PI) of middle cerebral artery velocity (MCAv) with an increase in systemic pulse pressure (Xu et al., 2012). Therefore, coffee drinking-induced increase in arterial stiffness may increase pulsatile stress which may cause to microvascular damage at highly-perfused organs, such as the brain (Zarrinkoob et al., 2016). The purpose of the present study was to examine whether coffee intake elevates PI of MCAv which is associated with an increase in baPWV. Methods Ten healthy young subjects participated in the present study. Arterial blood pressure and MCAv were measured throughout the experiment. Also, the baPWV and PI of MCAv were calculated under two different conditions; coffee and decaffeinated coffee-intake conditions. After baseline measurement in upright sitting position, each subject drank coffee (250ml, caffeine 150mg) or decaffeinated coffee (250ml) randomly. Results Coffee intake increased mean arterial blood pressure ($P < 0.01$) with decreases in mean MCAv and MCA conductance index ($P = 0.02$, $P < 0.01$). Also, coffee increased baPWV, while it did not change PI of MCAv compared with decaffeinated coffee. Discussion Main finding of the present study is that coffee intake does not increase PI despite an increase in baPWV. This findings suggest that coffee drinking dose not increase pulsatile stress in the intracranial cerebral circulation. Thus, acute increase in arterial stiffness after coffee intake does not impair cerebral blood flow regulation, indicating that coffee intake induced increase in risk of ischemic stroke may not be associated with an elevation in arterial stiffness in the systemic circulation. FLUTTERING ON OXYGEN PULSE DURING EXERCISE IN DIASTOLIC HEART FAILURE

ROBERTO, S., MULLIRI, G., MILIA, R., BASSAREO, P., SOLINAS, R., PINNA, V., SAINAS, G., CRISAFULLI, A.

University of Cagliari

Oxygen pulse (OP) is a quantity defined by the oxygen uptake (VO_2)/heart rate (HR) ratio and represents the amount of oxygen being consumed by the body for each single cardiac beat. Moreover, it is an index of stroke volume (SV). In normal subjects, evidence suggests that this parameter increases linearly with respect to workload. Moreover, other research has demonstrated that, in the presence of cardiovascular disease such as ischemic myocardial disease and systolic heart failure, OP does not increase linearly with the increasing effort. Rather, it shows a leveling-off behavior at relative mild work intensities. However, to date there is not study on the OP time course in patients with diastolic heart failure (DHF). This investigation was set to analyze the difference in the OP time course during an incremental exercise test in DHF patients and normals. Methods: Two groups took part in this study: CTL group composed by 8 healthy subjects (3 females, 33.2 ± 6 yrs); and DHF group composed by 9 patients suffering from DHF (4 females, 59.8 ± 9.4 yrs). Each individual performed an incremental exercise test with on an electromagnetically-braked cycle-ergometer until exhaustion during which cardiopulmonary (CPX) parameters were collected. Workload, VO_2 , and HR were assessed throughout the test. OP was also calculated as VO_2/HR . Results: The analysis of OP time course revealed that this parameter was significantly different between groups. In detail, in the CTL group OP continuously increased from 25% to 100% of the workload achieved ($+7.04 \pm 3.99$ ml/bpm in the difference between 100%-25% workloads), whereas in the DHF group it showed a blunted increment ($+3.31 \pm 2.74$ ml/bpm in the difference between 100%-25% workloads, $p < 0.05$ vs the CTL group). Similarly, in the transition from 75% to 100% of the workload achieved patients showed a reduced capacity to increase OP as compared to normals ($+0.68 \pm 0.65$ vs. $+2.98 \pm 1.68$ respectively, $p < 0.05$). Conclusions: This investigation demonstrates that DHF patients can not properly increase OP during incremental exercise. This finding is in accordance with their impaired capacity to recruit the pre-load reserve and to enhance SV. Finally, these results indicate that OP can be useful in order to detect differences between normals and DHF patients during the CPX test. References: 1 Crisafulli A et al. THE EFFECTS OF EXERCISE TRAINING ASSOCIATE WITH LOW-LEVEL LASER THERAPY ON BIOMARKERS OF BROWNING IN OBESE WOMEN

CAMPOS, R.M.S.1, DÂMASO, A.R.2, MASQUIO, D.C.L.2, DUARTE, F.O.1, SENE-FIORESE, M.3, AQUINO JR, A.E.3,4, TOCK, L.5, BAGNATO, V.S.3,4, PARIZOTTO, N.A.1,4

Introduction Recently investigations suggest the benefits of Low-Level Laser Therapy (LLLT) in improvement of body contouring noninvasive treatment. However, the mechanism for such potential effects associated to exercise training (ET) to reduce body fat, inflammation, insulin resistance and possible implications in browning adiposity process still unclear. Methods It was involved 49 obese women, aged of 20-40 years, body mass index (BMI) 30-40 kg/m². The volunteers were allocated in Phototherapy (ET-PHOTO) and SHAM (ET-SHAM) groups. Interventions consisted on exercise training and application of phototherapy post exercises during 4 months. Body composition, lipid profile, insulin resistance, atrial natriuretic peptide (ANP), WNT5 signaling, interleukin-6 (IL-6) and fibroblast growth factor-21 (FGF-21) were measured. Results It were demonstrated improvement in body mass, BMI, fat mass, lean mass, visceral fat, waist circumference, insulin, HOMA-IR, total cholesterol, LDL-cholesterol, triglycerides and ANP in both groups. Only ET-PHOTO group showed reduction in interleukin-6 and increase in WNT5 signaling. Moreover, it was showed that exercise training associated to LLLT is more effective than exercise training alone to reduce fat mass, insulin, HOMA-IR and to promote change in FGF-21 concentrations. Discussion In the present investigation it was confirmed that exercise training associate to LLLT promote an improvement in body composition, inflammatory process as previous demonstrated (da Silveira Campos et al., 2015; Duarte et al., 2015; Sene-Fiorese et al., 2015). In highlight, in ET-PHOTO group was showed benefic modifications of WNT5 signaling, FGF-21 and ANP, possible biomarkers associated with browning adiposity process, suggesting that this kind of intervention promote results applicable in the clinical practice to control of obesity and related comorbidities. ACUTE AND TWO-WEEK EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING AND ENDURANCE TRAINING ON FLOW-MEDIATED DILATION

RECTOR, M., MARTINEZ-VALDES, E., KOTSCH, P., MAYER, F.

University of Potsdam

INTRODUCTION: Endothelial dysfunction is an early clinical biomarker of atherosclerosis and cardiovascular risk. Studies have demonstrated the benefits of long-term high-intensity interval training (HIIT) and endurance training (ET) on the surrogate marker, flow-mediated dilation (FMD). However, even in healthy populations, there is still a lack of knowledge regarding their acute effect, minimum effective dose and possible relations between the two. PURPOSE: To investigate the acute and two-week effects of HIIT and ET on FMD in young healthy adults. METHODS: Twelve healthy men (29 ± 3 yr.; 177 ± 7 cm; 78 ± 8 kg) were assigned to either HIIT ($n = 7$) or ET ($n = 5$) and performed six training sessions over two weeks. Each session consisted of either 8-12 intervals at 100% peak power output (335 ± 55 W) separated by 75 s of recovery (HIIT) or 90-120 min continuous cycling at 65% $\text{VO}_{2\text{peak}}$ (165 ± 20 W, (ET)) (HIIT vs. ET total exercise volume: ~1375 kJ vs. ~6250 kJ). Baseline FMD of the brachial artery was assessed using B-mode ultrasound prior to training intervention, acutely after the first training session and again after two weeks of intervention. $\text{VO}_{2\text{peak}}$ and peak power output were determined pre- and post-intervention. Data are described descriptively (means \pm SD). To investigate differences between baseline and post-exercise values, a two-way repeated measures ANOVA (between and within factors) was employed, ($\alpha = 0.05$). Correlations between acute and two-week effects were analyzed with Pearson's correlation coefficients (r). RESULTS: Preliminary results show FMD is decreased acutely after both HIIT ($8.3 \pm 2.1\%$ v. $4.7 \pm 2.3\%$) and ET ($10.2 \pm 2.0\%$ v. $2.8 \pm 2.7\%$), $p = 0.02$, with a significantly greater decrease immediately after ET, $p =$

0.01. These changes and differences were independent of baseline artery diameter and shear stress. Although increases in VO_{2peak} (HIIT: 44.5 ± 7.6 v 47.3 ± 8.6 ml/kg/min; ET: 43.8 ± 7.6 v 47.3 ± 5.0 ml/kg/min, $p = 0.001$) and peak power output (HIIT: 4.3 ± 0.7 v 4.6 ± 0.6 W/kg, ET: 4.3 ± 0.4 v 4.6 ± 0.3 W/kg, $p = 0.001$) were observed, no changes in FMD were found after two weeks of either HIIT ($8.3 \pm 2.1\%$ v $7.6 \pm 1.8\%$) or ET ($10.2 \pm 2.0\%$ v $10.7 \pm 2.5\%$), $p = 0.31$. No relationship between acute and two-week FMD effects was found in either group (HIIT: $r = 0.46$, $p = 0.55$; ET: $r = -0.23$, $p = 0.62$). CONCLUSIONS: Considering differences in total work and volume, HIIT and ET both provoked acute reductions in FMD with ET having greater effect. However, no improvements in FMD could be demonstrated after two weeks of training despite both HIIT and ET enhancing VO_{2peak} and peak power output. Future studies should include longer interventions and more heterogeneous cohorts to help clarify the minimum effective dose of exercise to elicit favorable FMD adaptations and if acute effects of exercise on FMD could help predict intervention outcomes. EFFECTS OF PILATES EXERCISE ON S-IgA SECRETORY LEVELS IN OLDER WOMEN

HWANG, Y., PARK, J., LIM, K.

Konkuk University

Effects of Pilates exercise on S-IgA secretory levels in older women Yoonyoung Hwang¹, Jonghoon Park², Kiwon Lim^{1,3*} ¹Physical Activity & Performance Institute, Konkuk University, Seoul, Republic of Korea ²Department of Physical Education, Korea University, Seoul, Republic of Korea ³Department of Physical Education, Konkuk University, Seoul, Republic of Korea Purpose The purpose of this study was observed whether the mucosal immune function could change during acute high-intensity exercise after 3 months of Pilates exercise. METHODS Subjects The study population comprised 12 older women who were divided into a Pilates group (PG, n=6) that participated in a Pilates exercise program and a control group (CG, n=6) that did not participate in an exercise program. Study design The Pilates exercise program Before and after was performed for 3 months. In addition, acute high-intensity exercise was performed before and after the 3-month Pilates exercise program, and saliva samples were obtained immediately after exercise and at 30 and 60 min after exercise. Pilates exercise program The experiment group (PG group) carried out the program for twelve weeks (three days a week, 50 minutes a session). The intensity of the exercises was 40% of the Target Heart Rate (THR) at the beginning and was progressively increased to 60% of the THR by the end of the study. Aerobic capacity/graded exercise test All subjects performed a trial consisting of 50 rpm with 50 watts for a 6-minute single-stage protocol. If HR was < 130 bpm at the end of the exercise session, the workload was increased to 60 watts at 60 rpm for 6 more minutes. Saliva collection Saliva samples were collected in 10 ml tubes. The acute exercise was always performed between 09:00 and 10:00 AM. To measure salivary flow rate, saliva was collected in a tube for 15 min. Results Mucosal immune function before and after the 3-month Pilates exercise program The exercise intensity was measured during the 3-month Pilates program and was 45% of the maximum HR at 8 weeks and 61% of the maximum HR at 3 months. Mucosal immune function after acute high-intensity exercise before and after the 3-month Pilates exercise program (a) Salivary flow rate After the 3-month Pilates exercise program, salivary flow rate was significantly higher before and after acute high-intensity exercise at all-time points in the PG than in the CG. (b) Absolute S-IgA concentration This level was sustained 30 min after acute exercise in the PG, but the S-IgA level decreased 30 min after acute exercise in the CG. (c) S-IgA secretion rate The S-IgA secretion rate was significantly higher at 30 min after acute high-intensity exercise in the PG than in the CG. Conclusion This study suggests that participation in a moderate-intensity Pilates exercise program can increase the resting salivary flow rate in older women. Furthermore, a Pilates exercise program can increase the S-IgA secretion rate when needed during high-intensity physical activity.

EFFECTS OF SUPINE IMMERSION OF THE BODY IN WATER ON THE REGIONAL PULSE WAVE VELOCITY

SAITO, T.1, NISHIMURA, M.2, MURATA, M.3, YOSHIOKA, A.4, ONODERA, S.1

1Kawasaki University of Medical Welfare, 2Tottori University, 3Graduate School, Kawasaki University of Medical Welfare, 4Okayama University

Background: A human body is immersed in water is affected by the physical properties of water and accordingly manifests physiological responses. In this study, we compared the brachial-ankle pulse wave velocity (baPWV) of the body when it was in the supine position at rest on the ground with that when it was immersed in water at a temperature of 30°C. The results showed that the baPWV in the supine position in water was significantly higher than that at rest on the ground. However, baPWV is an indicator of arterial stiffness, including both elastic and muscular arteries, and therefore, it is difficult to determine in terms of arterial stiffness which parts of the body are affected by the immersion in water at 30oC. Thus, this study aimed to demonstrate the effects of supine immersion of the body in water on the regional pulse wave velocity. Method: The subjects were eight healthy adult males. Measurements were conducted during the 15 min of rest in the supine position at the poolside with a room temperature of $28.3 \pm 1.3^\circ\text{C}$ and humidity of $84.0 \pm 6.6\%$. Similarly, measurements were conducted during the 15 min of immersion in water at a temperature of 30oC. The participants were in the supine position and were fully immersed in water except for the face. The parameters measured were baPWV, heart-carotid PWV (hcPWV), heart-femoral PWV (hfPWV), femoral-ankle PWV (faPWV), heart rate, blood pressure in the upper arm and ankle, rectal temperature, skin temperature (using the 4-point method), and skin blood flow at the dorsum of the foot. Results and Discussion: The baPWV, faPWV, and diastolic blood pressure values in the ankle during immersion in water were significantly higher than those in the supine position at rest on the ground ($P < 0.05$). Rectal temperature, skin temperature, and skin blood flow values were all significantly lower when immersed in water compared with those in the supine position at rest on the ground ($P < 0.05$). There was a significant positive correlation between faPWV and baPWV at 5, 10, and 15 min after entering the water (5min: $r = 0.94$, $P < 0.01$; 10min: $r = 0.80$, $P < 0.05$; 15min: $r = 0.93$, $P < 0.01$). The pulse wave is conducted from the central arteries to the peripheral arteries. The faPWV is an index of muscular arterial stiffness. The results of this study suggest that increases in baPWV associated with supine immersion of the body in water may not be caused by changes in both elastic and muscular arterial stiffness but by changes in only muscular arterial stiffness. Conclusion: The results suggest that faPWV may be associated with an increase in baPWV during supine immersion of the body in water. [This work was supported by JSPS KAKENHI Grant Number 15H06786.]

FUNCTIONAL ASSESSMENT OF SEVERE HAMSTRING MUSCLE DAMAGE FOLLOWING INTENSIVE ECCENTRIC EXERCISE: DIFFERENCES BETWEEN AND WITHIN SUBJECTS

CARMONA, G.1, PADULLÉS, J.M.1, SERRANO, D.1, RODAS, G.2, NESCOLARDE, L.3, ALOMAR, X.4, CUSSÓ, R.5, CADEFAU, J.A.1,5

1:INEFC-UB (Barcelona, Spain); 2:Medical Department, Futbol Club Barcelona, (Barcelona, Spain); 3:Department of Electronic Engineering, UPC, (Barcelona, Spain); 4:Clinica Creu Blanca (Barcelona, Spain)

Introduction The aims of this study were to investigate the degree of damage inflicted to the hamstring muscles by an intensive voluntary eccentric exercise and to analyse differences in the extent of damage between-subjects and within-subjects (limb-to-limb comparison). **Methods** Thirteen healthy and physically active men (age 22.9 ± 2 yr) performed six sets of 10 eccentric unilateral hamstring leg curls (EULC) (Prone Leg Curl TechnogymTM, Italy) at 120% of their 1-repetition maximum (1-RM) with each leg, with 3-min rest between sets. Proxy markers of exercise-induced muscle damage (EIMD) such as force-generating capacity (FGC) (measured as maximal isometric voluntary contraction (MVC)), creatine kinase (CK) and magnetic resonance imaging (MRI) transverse relaxation time (T2) were measured at baseline and at regular intervals for 7 d after exercise. **Results** Two groups of subjects were identified according to the extent of EIMD reflected by MVC declines: high responders (HR) (n=10) and moderate responders (MR) (n=3) (3). Significant differences were also found in MVC within-subjects (limb-to-limb comparison) from the HR group. Changes in the CK serum levels after EULC were significantly different between HR and MR, and were correlated with MVC losses. The MRI T2 analysis revealed that semitendinosus (ST) was the hamstring muscle mainly damaged by EULC. ST T2 values obtained 7 d after exercise from the leg whose hamstring muscles showed the greatest FGC decline were correlated to MVC reductions but no correlations were found between T2 values and MVC reductions in the leg whose hamstring muscles showed the lesser FGC decline. **Discussion** Although large differences between subjects (HR and MR) were found, results challenge the notion that severe EIMD in humans is restricted to electrical stimulation protocols (1). CK reflects the amount of damage, especially when damage becomes severe (2). Within-subjects (limb-to-limb comparison) differences reveals that experimental designs using contralateral limbs as a control need to take into account that different degree of hamstring damage can be induced between legs. When muscle function is recovered (i.e., MVC), long-lasting increases in T2 values suggests an adaptive process rather than EIMD. **References** 1. LEUKOCYTE ALTERATION IN RESPONSE TO A SOCCER GAME

DEVRNJA, A., BARIŠIĆ, V., BAŠIĆ, M., MATKOVIĆ, B.R.

Faculty of Kinesiology

Introduction Soccer is one of the most popular modern sports played by men and women all around the world. It is estimated that players cover approximately 8 to 13 km per game, including different intensities of movement: walking, moving backwards, jogging, running and sprinting. During the game soccer players experience a number of short accelerations and decelerations at near maximal or even maximal intensities that could represent an important source of muscle damage and inflammation. The aim of the study was to determine the effect of soccer game on changes in leukocyte subpopulations in young soccer players. **Methods** 44 male field players aged 16 to 18 years, members of two soccer teams competing on junior national level, volunteered to participate in this research. All subjects signed informed consent. The study was carried out in accordance with and approved by the Research Ethics Committee of Faculty of Kinesiology University of Zagreb. 30 minutes before and immediately after the game (2 x 45min) blood samples were taken and leukocyte numbers were determined. Focus X2 was used to analyze player on-field activities. Statistical computations were performed using Statistica for Windows software. **Results** Total absolute number of leukocytes increased significantly from 5271 to $9465 \times 10^9/L$. Compared with circulating numbers at rest before the game increased number of neutrophils, eosinophils and monocytes were determined, while the number of lymphocytes significantly decreased. Significant differences were determined among the changes according to the player's position. **Discussion** The changes in total leukocyte numbers and all leukocyte subpopulations were identified. The similar changes were observed for all positions of players, but the level of changes was different. In goalkeepers the changes were not significant which is in accordance to their lower load during the game. More pronounced differences were present for defenders and midfield players. **Conclusion** These large increases in total number of leukocytes and especially in segmented neutrophils from pre-match to post-match are in agreement with other studies observing muscle damage changes in soccer players during the game. The correlation with distances covered was noticed. **References** Meyer T, Meister S (2011). Routine blood parameters in elite soccer players. *Int J Sports Med*, 32(11):875-81. INTRODUCTION Trail running consist in long-distance outdoor running through mountains, backcountry and/or deserts. As is known, inadequate fluid strategies in prolonged exercises can lead to dehydration, negatively affecting health and performance. Body mass (BM) is usually used to control the hydration status. Other techniques, such as BIVA, have emerged for the assessment of hydration variations. This study applied BIVA to assess possible hydration changes evoked by different distances of trail running (14km, 35km and 52km) in three groups of trail runners (TR). **METHODS** 56 TR (14km: n=14; 35km: n=28; 52km: n=14) were assessed before and after running (14km: 102 ± 24 min; 35km: 228 ± 42 min; 52km: 408 ± 78 min). A 50 kHz, phase-sensitive bioimpedance analyser (BIA-101 ASE; Akern Srl) was used to measure resistance (R) and reactance (Xc). Electrodes (Biatriode, Akern Srl) were placed according to the standard tetrapolar electrode placement. Whole-body impedance vectors were analysed using the RXc graph method. Hotelling's T2 tests were performed to analyse

the vectors of TR. RESULTS Significant changes were observed after runs in BM ($p<0.01$): 14km:-0.9±0.9kg; 35km:-2.5±1.6kg; 52km:-2.2±0.8kg. Athletes showed vectors significantly shifted to the left compared to their healthy reference population ($p<.001$). No statistical differences were found in BIVA between athlete groups (Fig. 1). BIVA showed significant whole-body vector migration after runs in all groups ($p<.001$) (Fig. 2). DISCUSSION Differences in BIVA between TR and the reference population indicate increased body cell mass and fluid content, maybe due to sport adaptations (Micheli et al., 2014). Significant differences in BM were found after runs. Additionally, BIVA also showed significant vector migrations after exercise, identifying fluid loss and likely indicating fluid shifts between intracellular and extracellular compartments (Gatterer et al. 2014). Surprisingly, 52km runners showed a vector displacement smaller than 14km and 35km runners. Weather conditions, previous performance level, running intensity, and fluid/food intake strategy during the run, could explain these results and should be taken into account in future investigations to determine the causes of the vector migration. Therefore, BIVA appears to be sensitive to hydration changes in different distances of trail running. Further research is needed in order to support these findings.

INFLUENCE OF EXERCISE INTENSITY ON CHANGES IN HUMAN SKIN-GAS ACETONE CONCENTRATIONS FOLLOWING SUBMAXIMAL CYCLE EXERCISE

ITO, H.1, MATSUURA, K.1, TAMURA, K.1, YOSHII, Y.1, KATO, H.1, UTSU, Y.1, TAKAI, S.1, OHKUWA, T.1, TSUDA, T.1

Introduction Increased ketone bodies (3-hydroxybutyrate, acetoacetate and acetone) during exercise are results of fatty acids oxidation in the liver, and export to peripheral tissues, such as the brain, heart, kidney and skeletal muscle for use as energy fuels (Mitchell et al. 1995). Because acetone is generated from decarboxylation of circulating acetoacetate, a few studies (Mori et al. 2008, Yamai et al. 2009) have reported increased human skin-gas acetone concentrations according to exercise intensity. On the other hand, Romijn et al. (1993) have reported that peripheral lipolysis was stimulated maximally at 25 % VO_{2max} during constant-load exercise. However, no one has confirmed influence of exercise intensity on changes in skin-gas acetone concentrations during submaximal exercise. Therefore, the purpose of the present study was to examine whether differences in submaximal exercise intensity would affect on changes in skin-gas acetone concentrations or not. . Methods Ten healthy male students randomly performed three kinds of constant-load (10, 30, 60% HRmax) cycle exercise for 30 min. The skin-gas samples were obtained by the covering left hand for 30 sec with a polyfluorovinyl bag (Tedlar bag; GLScience, Tokyo, Japan) in which pure nitrogen gas was introduced, and collected in a sampling bag at rest, 3, 6, 9, 12, 15, 20, 30 min after, and 5, 10, 20 min recovery of the exercise. Acetone concentration was analyzed by gas chromatography Results Skin-gas acetone concentrations significantly increased during 30 and 60% HRmax exercise compared to the resting values ($p<0.01$), however, 10% HRmax exercise did not change skin-gas acetone concentrations significantly. Thus, skin-gas acetone levels following 30 and 60% HRmax exercise were significantly ($p<0.01$) higher than 10% HRmax exercise. Discussion In this study, more than 30% exercise intensity increased skin-gas acetone concentrations and reached almost maximum. These results indicated following possibilities. First, the production of ketone bodies in the liver might be reached maximum (Romijn et al. 1993) during 30% HRmax exercise for 30 min and eliminated as expired air and (or) skin-gas acetone (Yamai et al. 2009). Second, the total amount in ketone production in the liver and consumption in peripheral tissues such as skeletal muscles might be same between 30 and 60 % HRmax exercise. ISCHEMIC PRECONDITIONING IMPROVES CARDIAC AUTONOMIC RECOVERY IN MIDDLE-AND LONG-DISTANCE RUNNERS: A RANDOMIZED, PLACEBO AND NOCEBO-CONTROLLED STUDY

PAULA-RIBEIRO, M., FREITAS, T.O., SABINO-CARVALHO, J.L., LOPES, T.R., FERREIRA, T.N., SUCCI, J.E., SILVA, A.C., SILVA, B.M.

Federal University of Sao Paulo

Introduction: Vagal reactivation and sympathetic withdrawal to the heart take place during recovery from exercise (1). This can be assessed by heart rate recovery (HRR) and used to monitor athletes' recovery and performance (2). Ischemic preconditioning (IPC) has been shown to improve exercise performance (ref. 3 for review). However, the effect of IPC on cardiac autonomic recovery remains uninvestigated. Herein, we tested the hypothesis that IPC improves HRR in middle-and long-distance runners. Methods: Eighteen middle-and long-distance runners [14 males (mean±SD: 22±3 yrs; VO_{2max} 67.2±5.1 ml/kg/min) and 4 females (24±4 yrs; VO_{2max} 55.8±4.1 ml/kg/min)] were submitted to three interventions, in random order [IPC; sham ultrasound session (SHAM); and resting control (CT)]. Subjects were told that: 1) IPC and SHAM would similarly improve recovery compared to CT, to control for placebo; and 2) IPC would cause no harm, despite circulatory occlusion pain, to avoid nocebo. Then, subjects underwent a maximal discontinuous incremental test (30-s interval each 3 min) on a treadmill. Blood was drawn for lactate analysis. Ten min later, a supramaximal constant test was performed till exhaustion. HRR after 30 s (HRR30s) and short-term time constant of HRR (T30) were calculated after each stage of the incremental test. HRR30s, T30 and HRR after 60 s (HRR60s) and 120 s (HRR120s) were calculated after the constant test. Results: The lactate threshold (LT) corresponded to 85±4% of peak velocity. IPC increased the HRR30s only at 70% (IPC: 31±2 vs. SHAM: 26±2 vs. CT: 26±3 bpm, $P<0.01$) and 75% (IPC: 29±2 vs. SHAM 24±2 vs. CT 25±2 bpm, $P<0.01$) of peak velocity. IPC did not change T30 in the incremental test, and HRR30s, T30, HRR60s and HRR120s in the constant test ($P>0.05$). Discussion: IPC improved cardiac autonomic recovery from exercise in middle-and long-distance runners and this effect was independent from placebo. The IPC effect was observed only below the LT, which indicates it was intensity-dependent. References 1. Lamberts RP, et al. FUNCTIONAL OUTCOMES AND MUSCLE PROTEINS INTO CIRCULATION AFTER ECCENTRIC EXERCISE IN HUMANS

KOLLIAS, L.1, PAPADOPETRAKI, A.1, TOUMPOULIDIS, K.1, PHILIPPOU, A.2, MARIDAKI, M.1

National and Kapodistrian University of Athens

Introduction A series of eccentric contractions can result in muscle damage characterized by sarcomere overstretching, loss of sarcolemma integrity, leakage of muscle enzymes into the bloodstream and functional impairment of the exercised muscle (Clarkson et al., 1992). The concentration of these enzymes into the circulation depends on their structural size and the degree of muscle damage (Heavens 2014). The aim of the present study was to examine functional outcomes and muscle proteins into circulation after an eccentric exercise protocol in humans. Methods Nine healthy men (years: 23±3.4, height: 180±3cm, mass: 83.5±10.8kg, BMI: 25.76±2.56) performed 8 sets of 6 maximal eccentric actions of the knee extensors muscles of one leg. Baseline measurements including maximum strength, perceived muscle soreness evaluation (palpation and flexion-extension), range of motion (knee angle flexion) and proprioception (knee position sense) were performed in each leg 2 days prior to eccentric exercise, immediately after, as well as 48h and 96h post exercise. Blood samples were also collected at each testing session before the functional measurements and were analysed for CK, MB, LDH, AST. One-way ANOVA with repeated measures was used for statistics. Results Eccentric exercise protocols 14.2mm in a 100 mm visual analogue scale at 0h, 48h and 96h, respectively. Knee angle flexion decreased from 126.6° at baseline to 112.6, 113.8, and 114.2 degrees, and a deflection of 10.4, 7.9, and 5.9 degrees was reported during the position sense test, at 0h, 48h and 96h post-exercise, respectively. Baseline values for CK, MB, AST, and LDH were changed from 170 U/L, 55µg/L, 26 U/L, 147 U/L, respectively at baseline to CK: 227, 5494, 9770 U/L, MB: 71, 96, 99µg/L, AST: 26, 91, 191 U/L, LDH: 152, 301, 441 U/L, at 0h, 48h, 96h, respectively. Discussion Our findings suggest that the eccentric exercise protocol used in this study resulted in muscle damage, as reflected by the prolonged force loss, delayed onset muscle soreness range of motion impairment, and muscle proteins release into circulation post-exercise. These findings suggest that the eccentric protocol caused a severe muscle damage based on the CK levels (>10000 U/L) combined with the degree of force loss (by >50%) (Paulsen et al., 2012). Interestingly, the eccentric protocol led also to a prolonged impairment of proprioception of the exercised muscles. References Clarkson et al. Med Sci Sports Exerc 1992;24:512-20 Heavens et al. EFFECT OF EXERCISE AND GLUCAGON-LIKE PEPTIDE-1 ANALOGUES ON BODY WEIGHT AND GLUCOSE METABOLISM IN OBESE RATS

GHEZZI, A., OLIVEIRA, A.G., VECINA, J.F., LEITE, J.P., SILVA, C.G.B., DIAS, P., SAAD, M.J.A.

Unicamp

Introduction Because of the increase in the type 2 diabetes epidemic, research has been performed in an attempt to develop new therapeutic methods. A promising treatment for diabetes is the use of incretins (hormones that work to increase insulin secretion). Medications such as GLP-1 analogues have been used for diabetes treatment, as has exercise, but it is not clear whether there is a positive additive effect when exercise and GLP-1 analogue medications are combined for the treatment of type 2 diabetes. In light of this question, the aim of this study was to analyze the effect of exercise and GLP-1 analogue on the glucose metabolism of the obese rats. Methods Wistar rats were fed a high-fat diet (HFD) for 12 weeks and were then separated into four groups: the VEIC-S group received the vehicle solution and was sedentary; the VEIC-T group received the vehicle solution and exercise; the GLP-S group received GLP-1 analogue and was sedentary; and GLP-T group received GLP-1 analogue and exercise. Exercise consisted of one hour of swimming per day for two weeks. GLP-1 (Liraglutide, 100 mg / kg) was administered subcutaneously twice a day (9:00am and 4:00pm) for two weeks to the GLP groups. At the end of the experiment, body weight was measured on a digital scale. After six hours of fasting, intraperitoneal insulin tolerance tests (IP-ITTs) and intraperitoneal glucose tolerance tests (IP-GTTs) were performed. The rats were killed for blood sample collection. Results There was a difference in body weight (g) between the groups: VEIC-S: 574±70y; VEIC-T: 565±52y; GLP-S: 539±67x; and GLP-T: 511±68x. In the case of glucose, the following areas under the curve were found (mg/dl120min): VEIC-S: 20.326±1.621f; VEIC-T: 17.478±1.795g; GLP-S: 12.352±1.305e; and GLP-T: 12.890±2.267e. The following KITT values were found (%/min): VEIC-S: 2.26±0.93b; VEIC-T: 3.17±0.99ba; GLP-S: 3.45±0.88a; and GLP-T: 3.46±0.89a. The blood concentrations of insulin were found to be: VEIC-S: 5.69±1.82n; VEIC-T: 2.14±0.85o; GLP-S: 4.29±1.56n; and GLP-T: 2.52±1.66o. Finally, the blood concentrations of IL-10 were as follows: VEIC-S: 26.90±4.24j; VEIC-T: 32.33±6.66i; GLP-S: 38.95±15.00i; and GLP-T: 52.00±17.08m. Discussion GLP-1 analogue and exercise were found to be effective in decreasing body weight. There were also improvements in glucose metabolism and an increase in the circulating antiinflammatory cytokine IL-10. Therefore, some of the parameters revealed the positive additive effects of combining physical exercise and the administration of GLP-1 analogue.

EFFECTS OF CREATINE ADMINISTRATION ON SERUM CPK LEVELS AND SOME PHYSIOLOGICAL VARIABLES FOR ATHLETES DURING COMPETITION PHASE

SABRY, E.

Faculty of Physical education – Tanta University – Egypt.

Introduction: Training enhancers have developed greatly during recent years, especially in natural nutrition supplements(Moon et al 2015). Nutrition supplements are natural food products that athletes use for improving their athletic achievement to the max. Creatine is one of the most popular nutrition supplements with random and uncontrolled usage among athletes. Creatine plays a major role in energy metabolism in the musculoskeletal system. An average human body needs nearly 2 grams of creatine per day. Athletes consume high doses that exceed the real needs and actual production of creatine in the human body. The current research aims to identify the effects of creatine administration on serum CPK levels and some physiological variables among judokas. This is very important according to the widespread uncontrolled use of creatine among athletes. Methods: The researcher used the experimental approach (one-group design) with pre- and post-measurements. Participants (n=8) were purposefully chosen for the judo team of ALSAID Sports Club – Al-Mahalla Al-Kubra – Egypt. The researcher used the experimental approach (one-group design) with pre- and post-measurements. Blood samples were taken before creatine administration. Participants were asked to take 20 grams per day for four days during the first week (the loading phase) and then they were asked to take 5 grams per day for seven weeks. Creatine administration was with warm water to facilitate absorption. After eight weeks of creatine consumption, blood sample were taken as a post-measurement. Results: After creatine administration for (8) weeks, (t) calculated values reached (8.6) while its table value on $P \leq 0.05 = (1.86)$ with a variance percentage of 180% for CPK. No statistically significant differences were noticed for pulse or blood pressure. Discussion: Results indicated that although creatine supplementation was controlled, CPK serum levels increased significantly beyond normal levels (Wang, L. 2015). This particular

enzyme affects muscular work negatively and makes the athlete feel exhaustion rapidly (Sureda et al 2015). References: 1. Moon, A., Heywood, L., Rutherford, S. M., & Cobbold, C. (2015). VARIABILITY IN TOTAL HAEMOGLOBIN MASS TO ALTITUDE TRAINING

ERONEN, T.1, NUMMELA, A.2, KOPONEN, A.3, PELTONEN, J.3, TIKKANEN, H.1,3

1: University of Eastern Finland, Kuopio, Finland, 2: Research Institute for Olympic Sports, Jyväskylä, Finland 3: Foundation for Sports and Exercise Medicine, Helsinki, Finland

Introduction Athletes use high altitude training (HAT) to increase their total haemoglobin mass (tHbmass). Previous studies suggest that there are athletes who do obtain increase in tHbmass (responders) but some do not have response (non-responders) (McLean et al. 2013). Those athletes who do not get a response are less likely to repeat a HAT camp. Assuming that there are marked individual differences among athletes and the response to HAT is personal and repeatable we studied tHbmass in athletes who visited HAT camp and focused on those who visited at least twice. Methods Using carbonmonoxide rebreathing method (Koponen et al 2013) we measured tHbmass, blood volume (BV), plasma volume (PV), haemoglobin (Hb), hematocrit (HCT) in 53 athletes (mean 25 years, SD 6 years). There were total of 77 HATs (at least 21 days, 1400 - 2300m). The researchers did not control training or living during HAT. Athletes attended HAT as following: 1 HAT - n=39, 2 HAT - n=8, 3 HAT - n=5, 5 HAT - n=1. All HATs were also categorized as response and non-response. Results Comparing changes in those athlete who visited HAT camp at least twice tHbmass increased or decreased on a randomized fashion. In all the athletes participating HAT during the study, there was a response in 54 HAT with an increase (mean and range) in tHbmass 4,9% (0,2% - 12,8%), BV 0,9% (-10,1% - 10,5%), Hb 4,2% (-7,5% - 14,5%), HCT 5,0% (-8% - 15,2%) and a decrease in PV -1,9% (-16,8% - 15,7%). In 23 HAT (non-response) there was a decrease in tHbmass -2,8% (-12,9% - -0,1%), PV -5,8% (-30,9% - 8,2%) and BV -4,8% (-24,4% - 3,3%) and an increase in Hb 2,5% (-6,3% - 20,0%) and HCT 2,3% (-7,9% - 17,2%). Discussion According to our results it seems to be that athletes cannot be categorized as responders and non-responders but the response of HAT to tHbmass seems to be random though majority of the HATs (70 %) increased athletes tHbmass. Because we did not control the HAT camp there may have been factors (e.g. infection, ironstatus,injury) that alter training and living during the camp and therefore the response to HAT. In the future it is important to find out why some camps fail to give a wanted response and if there are some predictable factors that can be helpful when timing the HAT. SEX DIFFERENCES IN CHOSEN CYTOKINE CONCENTRATIONS FOLLOWING AN EXERCISE STRESS IN SOCCER PLAYERS

POKORA, I.1, ZEBROWSKA, A.1, KOCHANSKA-DZIROWICZ, Z.

the Jerzy Kukuczka Academy of Physical Education (Katowice, Poland)

INTRODUCTION The production of cytokines in response to exercise is directly linked to the duration, intensity of exercise, the number of muscle fibers recruited and the fitness level of subjects. Recently, researchers have suggested there are sex differences in the immune response to exercise (Northoff et al., 2008, Gillum et al., 2011). It is recognized that women have more brisk immune responses than men and that woman's immune responses are influenced by sex hormones (Timmons et al., 2006). Female sex hormones fluctuate during the menstrual cycle and one would expect that in women immune responses to exercise may depend on the phase of the menstrual cycle. This study investigated whether there are any gender and menstrual phase related differences for physiological strain and whether the cytokine alterations to exercise stress are different in male and female soccer players. METHODS 12 men (M) and 15 women (W) completed an incremental intensity running test to exhaustion. Women were tested during the follicular (F) and luteal (L) phase of the menstrual cycle. All subjects trained football for about 8 years and underwent medical evaluations at the same point of the pre-season training process. Before exercise body mass and body composition were determined. During exercise oxygen uptake (VO₂), heart rate (HR) and tympanic (T_{ty}) temperature were continuously recorded. Before and at the end of exercise a physiological strain index (PSI) was calculated. In the blood samples collected before and following exercise the selected cytokine levels (IL-1 beta, TNF-alpha and IL-6), AIAT, AspAT activity and sex hormones (estradiol-E and progesterone-P only in women) were determined. RESULTS There were significant gender differences in subjects' characteristics. The VO_{2max}, PSI and maximal power (W_{max}) were significantly higher in M than W. Despite higher T_{ty}max in M, the rise of T_{ty}/min, delHR, HRmax were similar in both groups. The analysis of blood samples showed there are significant gender differences in IL-1beta, AIAT and AspAT activity. There were no significant differences in TNF-alpha and IL-6 cytokine responses to exercise between the M and W. There were significant menstrual phase-related differences for PSI, W_{max}, E level and AIAT, AspAT activity in women. CONCLUSION There are gender and menstrual phase related differences in the physiological strain to exercise, however in relation to the PSI women have more visible cytokine responses to exercise than men. Women in the luteal phase demonstrated a slightly greater pro-inflammatory cytokine response to exercise than in the follicular phase. REFERENCES Gillum T, Kuennen M, Schneider S, Moseley P. (2011). CFDNA CHANGES IN RESPONSE TO SWIMMING TRAINING; A PILOT STUDY

MORAWIN, B.1, RYNKIEWICZ, M.2, POKRYWKA, A.2, ORYSIAK, J.3, ZMIJEWSKI, P.3, SITKOWSKI, D.3, ZEMBROŃ-ŁACNY, A.2

1: UPE (Poznań, Poland), 2: UZ (Zielona Góra, Poland), 3: IS (Warsaw, Poland)

Introduction The phenomenon of circulating cell-free DNA (cfDNA) concentrations is of importance for many biomedical disciplines including the field of exercise biochemistry and physiology. Increases of cfDNA due to exercise are described to be a potential hallmark for the non-functional overreaching (NFO) and overtraining syndrome (OTS) and might be related to, or trigger adaptations of, immune function induced by strenuous exercise. It is likely that cfDNA is released into the plasma by immune cells, endothelial cells and circulating endothelial progenitor cells. Chronic, strenuous exercise protocols, either long duration endurance exercise or regular high-intensity workouts, induce systemic inflammatory response that might lead to a slow, constant release of DNA fragments (Breitbach et al. 2012, Fatouros et

al. 2006, Velders et al. 2014). Yet, it has neither been implicated nor proven sufficiently whether cfDNA can serve as a marker for NFO/OTS in physically active men. The relevance of systemic inflammation and cfDNA with NFO/OTS still remains unclear. With this information, we designed the study to explain whether high level of blood cfDNA is caused by physical training at high intensity, and to assess the usefulness of cfDNA for monitoring of training load and to diagnose the NFO/OTS syndrome. Methods Fifteen young swimmers at 14-17 yr old (junior national team) participated in the 6-month study during intensive preparatory period for Junior Swimming Championships. At the every month of observation were performed the measure of maximal oxygen uptake ($\text{VO}_{2\text{max}}$), body mass and body composition as well as serum cfDNA, C-reactive protein (hsCRP), creatine kinase (CK) and uric acid (UA) and white blood cells count. Results There were significant changes in $\text{VO}_{2\text{max}}$, body composition (fat mass and free-fat mass) and serum cfDNA in young swimmers. The changes in cfDNA were related with training load and systemic inflammation (hsCRP and WBCs). Discussion/Conclusion This study demonstrates that serum cfDNA concentrations increase in proportion to training load, suggesting that cfDNA may be a sensitive marker for monitoring of NFO/OTS in young swimmers. HOW TEMPORAL PERCEPTION AFFECTS THE START OF SHORT-TRACK RUNNERS

FURUBAYASHI, T.1, UGAWA, Y.2, TERAO, Y.3

1) Tohoku Bunka Gakuen University 2) Fukushima Medical University 3) Kyorin University

Introduction: Can temporal perception affect that start of short-track runners? Imagine the beginning of a short-distance race in which processing of temporal information is especially important, when the runners prepare for the start on their mark. With "ready", "get set", they assume the starting posture and initiate a dash in response to the "go" signal. To study the effect of time perception on motor preparation required for this process, we used a task in which durations of two sounds presented in succession (S1, S2) were compared. **Methods:** Subjects were 14 healthy volunteers. The duration of S1 (standard) was fixed in each session, either at 700, 2100, and 3500ms. For each trial, the duration of S2 was selected from among seven possible different durations, longer or shorter than the standard. The subjects were instructed to compare the two durations as soon as S2 ended. Reaction time (RT) of key presses and positive answer rate (PAR), i.e., percentage of trials in which S2 was judged as being longer than S1, were measured for each S2. The duration of S2 at which PAR was presumed to reach 50% was defined as PAR50%. **Results:** PAR50% was almost identical to the S1 duration when S1 was 700ms, but became slightly shorter for longer S1 durations (2100, 3500ms). RT was longest when the difference between S1 and S2 was smallest, and became shorter as the difference became longer. RT shortened and reached a steady level when the difference (up to 40% of the S1 duration) was very large. This steady level was significantly shorter when the duration of S2 was longer than that of S1 than when S2 was shorter than S1. **Conclusions:** The present study suggests that time perception can affect how fast a runner can start dashing in response to a go signal. The fact that PAR 50% was shorter than S1 duration for longer S1 durations suggested that the actual duration of S2 get underestimated as the standard S1 duration becomes longer. Thus longer durations between "ready" and "get set" may lead to a tendency for premature start due to this underestimation. Longer RT as the difference between S1 and S2 became smaller may reflect the difficulty in discriminating similar time durations. On the other hand, as for the stable level of RT when difference in S1 and S2 durations was large, RT was longer when S2 was much shorter than S1 than when S1 was much shorter than S2. In the former case, subjects have to respond to the end of S2 which occurred before the memorized length of S1, so that the subjects have to start a motor response on detection of the end of S2, hence longer RT. In the latter case, the subjects already know at the end of S2 that the memorized duration of S1 have already elapsed, so that they can fully prepare the motor response, hence shorter RT.

CHANGES IN NEUROMUSCULAR JUNCTION MORPHOLOGY OCCURRING IN CONJUNCTION WITH MUSCULAR ATROPHY: A COMPARISON OF INACTIVITY, DENERVATION, AND AGING

NISHIZAWA, T., NORIKATU, K.

sigakkan junior university , Aichi University of Education

Introduction: Muscle atrophies as a result of inactivity. Inactivity has a profound effect on muscle both morphologically and functionally, but these changes are reversible. Once muscle becomes active again, it recovers. The neuromuscular junction (NMJ) is a site of neuromuscular signal exchange, and NMJs are sites that maintain neuromuscular function. The current study examined the effects of muscular atrophy on NMJ morphology. Inactivity, temporary denervation, and age were used to conduct an experiment to study muscular atrophy. **Methods :**Laboratory animals: The laboratory animals used were male Fischer 344 rats. 16week-old rats were used to study inactivity. Two groups of animals had their hindlimbs immobilized with a cast for 1 week or 2 weeks. A third group had its hindlimb immobilized with a cast. After two weeks of immobilization, to remove the cast, the animals were usually reared for two weeks. Temporary denervation was accomplished by freezing the sciatic nerve. Denervation was performed in 10weeks old rats. Changes in NMJ morphology were noted 3, 7, 14, and 21 days after freezing of the sciatic nerve. 17weeks old, 1years old, and 2years old rats were used to study aging. **Observation and Analysis of NMJ Morphology:** The muscle EDL was studied. The muscle was removed and then frozen. 50 μm thick longitudinal sections were prepared in a cryostat. Then stained for ChE and stained with silver. Images were imported from a microscope camera to a PC, and the length of the motor endplate (LEL), the area of the motor endplate (EpA), the area of the nerve terminal (NTA), and the diameter of muscle fibers (FD) at NMJs were measured. NMJ morphology was analyzed using the methods described by Fahim et al. **Results:**Findings suggested that 1 week of inactivity caused muscle to atrophy. However, abnormalities in the morphology of axon terminals at NMJs were not noted in rats that were immobilized for 1 week. A decrease in the area of the NMJ was noted in rats that were immobilized for 2 weeks. FD returned to its previous value in rats that were reared normally after immobilization. FD diminished significantly as a result of 2 weeks of inactivity, but it returned to its previous value 2 weeks after activity resumed. There were no changes in the indices of NMJ morphology. NMJs were not affected by inactivity. A decline in NTA was noted in NMJs. There were no changes in EpA. FD, EpA, EPL, and EpA/FD were significantly smaller in 1year-old and 2year-old rats in comparison to the same indices in 16weeks old rats. Morphological abnormalities evident in old age were noted in atrophied muscle fibers at NMJs. **Conclusion:** Muscular atrophy in conjunction with increased or decreased muscle activity changed the morphology of the NMJ. However, morphological changes that occur in conjunction with muscular atrophy and the restoration of that morphology were found to differ early in life and in old age. This finding suggests that the mechanism of muscular atrophy early in life differs from that in old age.

THE EFFECT OF LONG-TERM EXERCISE TRAINING AND HIGH-FAT DIET AND HIGH-CARBOHYDRATE DIET ON ENERGY SUBSTRATES UTILIZATION

TAEIN, L.

Konkuk University

Objectives: Long-term exercise training with high-fat diet (HFD) feeding could lead to increase the fat oxidation, also high carbohydrate diet(HCD) feeding with long term exercise training increase the carbohydrate oxidation at rest and during exercise in rodents and humans. However, the effect of long-term exercise training with high fat and carbohydrate diet feeding on respiratory exchange ratio (RER) and energy substrate utilization in mice has not been clarified yet. Therefore, we investigated the effects of exercise training with HFD and HCD on RER and energy substrate utilization, also we measured MCT1, MCT4 and Glut4, CS mRNA expression in gastrocnemius muscle. **Materials & Methods:** ICR male mice were fed with high-fat(HF) and high-carbohydrate(HC) for 12 weeks. After the 12 weeks, these mice were divided into 4 groups; high fat diet with exercise (HFD-Ex), high-fat diet without exercise (HFD), high-carbohydrate diet with exercise (HCD-Ex), high-carbohydrate diet with exercise (HCD). Exercise mice performed running exercise on a motorized treadmill (1 h/d, 5 d/wk, 12 m/ min, 12% grade, 65~70% VO₂ max) for 12 weeks. mRNA expression in muscle was analyzed by using PCR method. **Results & Findings:** Final body weight and fat mass were significantly higher in both HF groups compared with both LF group. 24-h RER were significantly lower in HF groups compared with LF groups, but there were no significant differences between exercise groups. RER during a 1-h exercise were also significantly lower in both HF groups compared with LF groups. On the other hand, RER during a 1-h exercise was significantly lower in HFD-Ex than in HFD although the exercise effect was not observed in LFD groups. The expression of GLUT4 mRNA was significantly higher HFD in compared with HCD. CS mRNA expression was significantly higher both HF groups in compared with HCD and HFD-Ex significantly higher than HCD-Ex. Also, MCT4 mRNA expression tend to higher both exercise groups compare to the without exercise groups but not significant differences. **Conclusion:** We confirmed that long term high fat diet feeding increases fat oxidation both at rest and during exercise. Especially our results provide important information that long term exercise training can further enhance fat utilization during exercise under the exposure to a high-fat diet feeding. However, the effect of dietary in MCT1, MCT4 and Glut4 mRNA expression involved in substrate utilization of carbohydrate does not appear, but not MCT4 mRNA has shown that higher in both exercise groups. Therefore further studies are needed to examine the protein of mRNA expression in substrate utilization of fat.

THE DIFFERENCE IN AGE IS NOT A KEY-FACTOR IN THE MODULATION OF ACUTE EXERCISE-INDUCED MUSCLE OXIDATIVE STRESS

BRANCHER, E., TROMM, C.B., SOUZA, P.S., PEDROSO, G.S., EFFTING, P.S., SILVA, L.A., SOUZA, C.T., PINHO, R.A.
UNESC

The difference in age is not a key-factor in the modulation of acute exercise-induced muscle oxidative stress INTRODUCTION The effects of exercise on ROS production and on the generation of reactive oxygen species and the response to muscle oxidative stress determines longevity. This study compares the effects of acute exercise with similar relative workload in rats with 3 and 18 months. METHODS The animals were divided into four groups ($n = 6$): control 3-months; exercise 3-months; control 18-months and exercise 18-months. Exercised groups underwent to a single bout of running with 60 minutes in the speed 0.8km/h (18 months) and 1.2 km/h (3 months). Metabolic parameters (lactate levels, glycogen content, succinate dehydrogenase levels, cytochrome c oxidase) and oxidative stress markers (activity of superoxide dismutase, catalase and glutathione peroxidase). RESULTS Evidence in this study shows that changes in the glycolytic and oxidative metabolism are similar in both groups exercised, suggesting that acute exercise at a moderate intensity affects the independent counsel age metabolism. In addition, the skeletal muscles (gastrocnemius) of animals from 3 to 18 months is similarly susceptible to oxidative damage, although age promote responses in different enzymatic antioxidant system. DISCUSSION The effects of exercise on the redox state are inconclusive because the literature have reported that exercise improves (Ghosh S), attenuates (Hatao H) or does not affect (Radak Z) redox homeostasis muscle. Our results show an increase in metabolic markers after acute exercise regardless of the age of the animals and similarity in oxidative damage despite the antioxidant enzymes present different modulation in older animals older animals compared with young animals. These results suggest that the effects of acute exercise at moderate intensity affect the metabolism of aged groups, affects the independent counsel age metabolism, and the differential response in the enzymatic antioxidant system between groups did not promote greater protection against oxidative damage. EFFECTS AND EFFICIENCY OF AEROBIC TRAINING AROUND PUBERTY

CSELKÓ, A.I., TÉKUS, É.I., VÁCZI, M.I., KÓSZEGI, T.Z., WILHELM, M.I.

1University of Pécs, Faculty of Sciences, Institute of Sport Sciences and Physical Education Pécs, Hungary 2University of Pécs, Medical School, Department of Laboratory Medicine Pécs, Hungary

Introduction Monitoring maturation and development among young athletes is an essential factor to the adequate training. Aerobic capacity, progresses age dependently, sensitive period of development is between prepubertal and pubertal ages (9-13 years). Results regarding the efficiency of aerobic training in young age groups are controversial. The aim of our study was to examine physiological, hormonal changes, muscle force of young prepubertal female handball players after an 8 weeks training period in the preparatory season. Methods 18 young female handball players (11.50 ± 0.56 yrs) participated in this study. Before and after the training period venous blood samples were collected (E, cortisol, T, GH levels were measured). Except two subjects players were before menarche. Anthropometric parameters were measured, the hand grip strength test and maximal concentric quadriceps and hamstring torque test were performed. All players took part in a spiroergometric treadmill exercise test (Bruce protocol) and changes in physiological parameters were monitored (e.g. HR, VO_{2max}, RR variability, RER) during the test. Besides regular handball practice a specific endurance program (20-25 min continuous running, 3times/week) was evolved. Paired sample t-test and bivariate correlation were used to analyze data. Level of significance was set at $p \leq 0.05$. Results Significant differences were found in certain anthropometric parameters after 8 weeks of aerobic training. Improvement but no significant difference was detected in relative VO_{2max} after the program (b: 43.32 ± 5.68 ml/kg/min, a: 44.05 ± 5.09 ml/kg/min). Better results were also recorded in force parameters, mean maximal concentric quadriceps torque was significantly ($p=0.022$) higher after (84.39 ± 15.35 Nm) then before (76.38 ± 15.93 Nm). Significantly higher ($p=0.033$) level of cortisol was detected after the training program (b: 340.39 ± 168.06 nmol/l, a: 423.74 ± 199.34 nmol/l). Discussion In accordance with earlier data there was no significantly higher VO_{2max} measured after 8 weeks of strong aerobic training, although young handball players

reached the ventilatory breakpoint later, while minute ventilation did not change. Suggesting that the quality of respiration is improved. Improvement in force parameters in prepubertal ages are the consequences of neuromuscular adaptation. To create efficient training programs, it is important to monitor the biological age/maturity parallel with physiological and anthropometric parameters of young athletes. DOES VITAMIN D IMPROVE PERFORMANCE OF ATHLETES?

GRIVAS, G.V., DAMASCENO, M.V.

Physical Education and Sport Science

Introduction Vitamin D can be synthesized endogenously by exposing the skin to UVB radiation of the sun (Deldicque & Francaux, 2015). Also, low vitamin D status has been linked to various cardiovascular diseases, hypertension and certain types of cancer (Halliday et al., 2011). Athletes have similar risk factors for vitamin D deficiency as the rest of the population. Its insufficiency results in increased risk of injury, poor health, and delayed recovery and therefore impacts athletic performance (Farrokhyar et al. 2015; Hamilton, 2011). Therefore, the aim of the present study is to investigate the effects of vitamin D on performance of athletes. Methods The following databases were searched: Pubmed, SPORTDiscus, Medline and CINAHL (Cumulative Index to Nursing and Allied Health Literature). In each database the title, abstract and keywords search fields were searched. The following keywords, combined with Boolean operators (AND, OR), were used: "vitamin D", "athletic performance", "antioxidants", "sports performance", and "muscle strength". Results There are only two studies in the literature showing beneficial effects of vitamin D supplementation on performance of athletes (Cannell et al., 2009; Yi et al., 2014). On the contrary, the majority of studies have shown no effect of vitamin D supplementation on performance (Close et al. 2013; Nieman et al. 2014; Shanely et al. 2014). Discussion These results indicate that there is uncertainty in regards to how vitamin D helps athletic performance. Also, there is little scientific evidence that vitamin D supplementation improves performance of athletes that are not vitamin D deficient. However, it is clear that vitamin D plays an important role in musculoskeletal health (stress fractures, viral respiratory tract infections) and in the prevention of chronic and acute diseases, such as: cancer, cardiovascular disease, type 2 diabetes and autoimmune diseases (Willis et al., 2013). ENDOCRINE AND INFLAMMATORY RESPONSE TO RESISTANCE TRAINING AT DIFFERENT TIMES OF DAY

MORRIS, T.E., VAN SOMEREN, K.A., BERK, E.S., PARKIN, J.

GlaxoSmithKline

Introduction The physiological response to resistance training (RT) has been well documented; however, the time of day to conduct RT in order to maximize adaptation is not well defined. This study investigated the effect of RT at different times of day on endocrine and inflammatory responses, and markers of muscle damage. Methods 18 healthy male subjects (age: 27.8 ± 4.7 yrs; stature: 179.6 ± 6.4 cm; body mass: 80.1 ± 9.1 kg) with 6 months (2 to 3 times per week) RT experience were randomised to three conditions in a crossover design: no resistance training (NRT), morning resistance training (MRT) and evening resistance training (ERT); each separated by seven days. Blood samples were taken at rest (prior to RT), and at 2, 4, 8, 12, 16, 20, 24, 30 and 36 hours post RT and NRT. Samples were analysed for cortisol, insulin, interleukin 6 (IL-6) and testosterone in all conditions, and for creatine phosphokinase (CPK) and high sensitivity C-reactive protein (CRP) in MRT and ERT conditions. Values were expressed relative to the corresponding time-point in NRT and differences between MRT and ERT were analysed using mixed-model analysis of variance (ANOVA). Results There were condition main effects between MRT and ERT for cortisol ($F= 6.20$; $P= 0.016$) insulin ($F=13.09$; $P= 0.0004$), testosterone ($F= 5.59$; $P= 0.019$), CPK ($F= 12.67$; $P= <0.001$) and CRP ($F= 17.4$; $P= <0.001$). There were time main effects for cortisol ($F= 5.08$; $P= <0.001$), insulin ($F= 19.19$; $P= <0.001$), IL-6 ($F= 2.14$; $P= 0.033$), testosterone ($F= 7.93$; $P= <0.001$), CPK ($F= 0.53$; $P= 0.833$) and CRP ($F= 1.02$; $P= 0.410$). Finally, there were condition by time interaction effects for cortisol ($F= 39.91$; $P= <0.001$), testosterone ($F= 16.09$; $P= <0.001$), and insulin ($F= 19.44$; $P= <0.001$). Post-hoc analysis showed cortisol was higher in ERT at 16 h ($P = 0.0037$); testosterone was higher in MRT at 4 h and 12 h ($P = 0.025$ and $P < 0.001$, respectively); and insulin was higher in ERT at 16 h ($p < 0.001$) and higher in MRT at 24 h ($P = 0.046$). Discussion Whilst there were some differences in cortisol, testosterone and insulin between ERT and MRT, these were not consistent across time points following the RT at different times of day. Further research is required to elucidate the differences and relative benefits of resistance training at different times of day. In particular, optimizing the timing of RT aligned with individualized physiological response could provide longitudinal accrued benefits to training response and adaptation.

PERIPHERAL RATHER THAN CENTRAL FATIGUE IS RESPONSIBLE FOR ROWING PERFORMANCE IMPROVEMENT WITH OXYGEN SUPPLEMENTATION

VOLIANITIS, S.1, BJARRUM, M.2, CARLSON, C.2, RASMUSSEN, P.3, OVERGAARD, A.3, FABRICIUS-BJERRE, A.3, SECHER, N.H.3, NIELSEN, H.B.3, PETERSEN, N.C.2

¹Dept. of Health Science and Technology, Aalborg University, ²Institute for Exercise and Sports Sciences and Dept. of Medical Physiology, ³Copenhagen Muscle Research Center, Dept. of Anesthesiology, R

Introduction Hyperoxic breathing may enhance rowing performance, presumably by restoring cerebral oxygenation (SCO₂), and thus attenuating central fatigue. However, considering that hyperoxia also attenuates peripheral fatigue, the contribution of central and peripheral fatigue to rowing performance is not known. This study evaluated the effect of oxygen supplementation on cerebral and active muscle oxygenation together with central and peripheral fatigue indices, i.e., reduction in maximal voluntary contraction (MVC) and transcranial magnetic stimulated (TMS) force generation. Methods Six competitive rowers performed 2000 m all-out exercise on a rowing ergometer in normoxia and hyperoxia (30% O₂) in a randomised double blind crossover design. Arm MVC was assessed with electromyography (EMG) of the m. biceps brachii and the m. brachioradialis. Voluntary activation of the elbow flexor muscles was assessed with TMS single pulses that were delivered to the motor cortex and evoked motor potential in the biceps brachii. SCO₂ and muscle (vastus lateralis) oxygenation were assessed with near infrared spectroscopy (NIRS). Results Arterial hemoglobin O₂ saturation was 92.5 +/-

0.2% during exercise in normoxia, while it was maintained at 98.9 +/- 0.2% in hyperoxia. SCO₂ decreased by 11% from resting baseline during exercise in normoxia, while it was maintained during hyperoxia. Muscle oxygenation decreased equally during normoxia (-35%) and hyperoxia (-32%), while rowing performance tended to increase during hyperoxia (-3 +/- 4 s, NS). Maximal rowing in normoxia resulted in a significant reduction (7.4 +/- 5.1 %) in MVC, while there was no difference in the extra force produced by TMS. Following hyperoxic exercise the MVC and TMS were not different than at rest. Discussion These data indicate that following maximal rowing the force generating capacity of the elbow flexor muscles is attenuated but it is restored with hyperoxia and suggest that the associated performance improvement with oxygen supplementation is attributed to alleviation of peripheral fatigue. EFFECT OF HEAT EXPOSURE AND EXERCISE ON FOOD INTAKE REGULATION

FAURE, C., CHARLOT, K., HENRI, S., HARDY-DESSOURCES, M.D., HUE, O., ANTOINE-JONVILLE, S.

Adaptation to Tropical Climate and Exercise Laboratory, EA3596, University of the French West Indies, Pointe-à-Pitre, Guadeloupe, France.

CONTEXT: Physical exercise might slightly increase energy intake but this compensation is far from completing the energy expended during exercise sessions creating therefore a negative energy balance. However, we still ignore whether living in a hot environment inhibits or stimulates exercise-induced weight loss. **OBJECTIVE:** The aim of the study was to determine the sole and combined (with exercise) effect of heat on acute energy intake (EI) and its hormonal regulation. **METHODS:** Ten healthy and physically active young men participated in four experimental sessions (40 min of rest and cycling at 60% of their VO_{2max} at 22 and 31°C in both conditions). This test period was followed by a 30-minute recovery period and then an ad libitum meal (ham and cheese sandwiches). Temperature was maintained until the end of the meals. Subjective ratings of hunger with visual analogic scales and plasma pancreatic polypeptide (PP), cholecystokinin (CCK) and ghrelin concentrations were determined. **RESULTS:** Subjective hunger scores and energy intake were not modified by exercise and/or heat. However, when energy expenditure during the 40-min sessions was subtracted to EI, relative energy intake was significantly decreased in the exercise session ($P=0.004$). Exercise increase plasma PP ($P=0.002$, respectively). Postprandial levels of CCK were elevated only in the rest conditions. Heat did not alter plasma levels of these different hormones. **CONCLUSIONS:** Exercise induced a short-term energy deficit. However, modifications in the hormonal regulation of food intake in response to short-term heat or combined heat and exercise exposure seem to be minor. These results suggest that physical activity interventions designed to manage weight require no particular adaptation to a hot environment.

THE EFFECT OF ONE BOTH ECCENTRIC EXERCISE FLEXORS ELBOW ON

NAMENI, F.1, MOHSENZADEH, M.2, POURSADRA, H.3

1.VARAMIN- PISHVA BRANCH, ISLAMIC AZAD UNIVERSITY, 2.KARAJ BRANCH, ISLAMIC AZAD UNIVERSITY, 3.D. EQUIPMENT

Introduction Skeletal muscle may develop adaptive chaperone and enhancement defense system through daily exercise stimulation. The present study investigated 3 types training alters the expression of chaperone proteins. These proteins function to maintain homeostasis, facilitate repair from injury and provide protection .Exercise-induced production of HSPs in skeletal muscle and peripheral leukocytes and, it may provide insight into the mechanisms by which exercise can provide increased protection against stressors .The aim of this study was to examine the effect of 3 types training on HSP70 expression and glucose. Methods Twenty training female performed one bout ,3 sets of 12 maximal eccentric actions of the elbow flexors of the nondominant arm . G-CSF,MPO , PGE2· and myoglobin (Mb) were measured before, immediately after, and for 2 hours after exercise. Results All data are expressed as means±SEM and analysis of variance(ANOVA) repeated measures and LSD test was used for postIP value was <0.05). There were no significant differences among in the changes in MPO and Mb measures ,but changes of G-CSF and PGE2 were Significantly (p < 0.05) . Discussion In conclusion, although there was evidence of severe muscle damage after the eccentric exercise, this muscle damage was not accompanied by any large changes in plasma concentrations. The minor changes in systemic concentration found in this study might reflect more rapid clearance from the circulation, or a lack of any significant metabolic or oxidative demands during this particular mode of exercise. Our results suggest that the intensity of exercise affects the magnitude of muscle soreness and blood markers of muscle damage and inflammation.

EFFECT OF INTERVAL HYPOXIC TRAINING ON EXERCISE PERFORMANCE OF JUDOISTS

SUKHOV, S.

National Anti-Doping Centre

Introduction One of the methods for increasing an exercise performance (EP) of athletes is the interval hypoxic training (IHT). Though the IHT is widely being used in training of athletes, to date there are not still available optimum training regimens for different sports. Goal of the study – to assess the effect of IHT on EP of judoists. Methods Twenty four elite judoists (12 athletes – trial group, 12 athletes – control group) were involved in the study. During the entire assessment, the both groups were coached with the same training program. In addition, the trial group exercised the IHT every other day. Total 10 sessions of IHT were applied. The BIO-NOVA-204S4 device was utilized for IHT sessions. Each IHT session lasted 60 minutes, during which there was provided the alternation of breathing for five minutes of air with normal and 10% lowered oxygen content. Prior to IHT and after the entire set of sessions the both groups of judoists were examined, with determination of lung vital capacity (VC), maximal breathing capacity (MBC), VO_{2max}, anaerobic threshold (AT) by blood lactate concentration, complete blood count, registration of ECG. There was made the assessment of EP on bicycle ergometer at a three-step discrete small, submaximal and maximal aerobic load (PWC130, PWC150, PWC170, PWCmax). Results VC and MBC did not change in both groups. The trial group showed growth of ET at heart rates (HR) 130 and 150 bpm by 16%, at HR 170 bpm by 7%, and at maximal HR by 4%. That is, there was noted the rise of ET mainly at the aerobic loads. In the control group, the EP virtually did not change at every HR regimen. The highest rise of EP was noted in athletes with a relatively lower initial level of it. No change of VO_{2max} was noted in both groups. The trial group demonstrated growth of AT from 147.3±2.6 to 157.7±2.8 bpm. No change of AT was noted in the control group. No change of red blood indicators was revealed in both groups. Conclusion The study findings demonstrate the positive effect of IHT on EP of judoists at heart rates 130 and 150 bpm. After the IHT the rise of AT was characteristic. The conclusion is that the IHT contributed to the increase of aerobic efficiency. The effect of IHT on EP showed substantial individual variations. sukhovsergey2004@mail.ru

Psychology

EXAMINING THE RELATIONSHIP BETWEEN JUNIOR ICE HOCKEY PARTICIPATION AND ALCOHOL CONSUMPTION

ROY, J., CAMIRÉ, M.

University of Ottawa

Introduction Research has shown how sport participants have higher rates of alcohol consumption than nonparticipants, with ice hockey having been identified as a sport where athletes are particularly involved in binge drinking (Ford, 2007). However, little is known as it relates to the psychosocial factors that influence alcohol consumption among ice hockey players within adolescence and emerging adulthood. Methods Using a case study approach (Yin, 2009), the purpose of this study was to examine alcohol consumption within a Canadian junior (17-21 years) ice hockey team over the course of an entire season. Semi-structured interviews were conducted at three different time points (beginning, middle, and end of season) with five male participants (two coaches and three players). All participants were of legal drinking age. The interviews lasted between 45 and 79 minutes ($M = 55:45$). The researcher was granted full access to all team facilities (e.g., locker room), with observations occurring during training camp, regular season games, tournaments, and playoffs. Results During the regular season, the locker room and a local bar close to the arena were identified as the areas most conducive to alcohol consumption after games, with beer being the preferred choice. During tournaments, excessive alcohol consumption was prevalent amongst all team members, with some indicating that drinking superseded playing ice hockey as their main motivation for taking part in the tournament. While intoxicated, team members engaged in drunk driving, risky sexual practices, and hotel vandalism, all practices reinforced by the chauvinist climate that existed within the team environment. Discussion Interest in the alcohol-sport relationship is growing, as evidenced by the special issue (June 2014) in the International Review for the Sociology of Sport. The current study contributes to the literature in this area by exploring in-depth how and why alcohol consumption occurs in Canadian junior ice hockey. As the findings indicate, alcohol consumption is inherently engrained within the fabric of ice hockey, with players and coaches often engaging in binge drinking that leads to risk-related behaviors. Despite having provided rich insights into the intricate inner-workings of alcohol consumption in ice hockey, the findings are limited in the generalizability as data were collected within a single team. Further research is warranted in different contexts (e.g., women's ice hockey) to ascertain if/how alcohol consumption manifests itself differently. References Ford, J. A. (2007). VALIDATION OF THE SPORT MULTIDIMENSIONAL PERFECTIONISM SCALE-2 FOR THE MEXICAN SPORT CONTEXT

PINEDA-ESPEJEL, H.A., ARRAYALES, E., TREJO, M., ARCE, R.

Universidad Autónoma de Baja California

Introduction Frost and cols. (1990) proposed six facets representing central aspects of perfectionist cognition, affect and behavior across life domains: personal standards; organization; concern over mistakes; perceived parental pressure; doubts about action; perceived coach pressure. An instrument designed to measure these aspects within the sporting context is the S-MPS-2 (Gotwals & Dunn, 2009). Thus, the ability to adequately evaluate perfectionism is a current need to the development of sport and sport psychology sciences in general, especially in Mexico where no such instrument has been validated. The aim of this study was to validate the factorial structure a Spanish version of the S-MPS-2 for the Mexican population. Methods Participated 192 sportsmen and women with a mean age of 20.63 years old ($SD = 3.73$). To adapt the S-MPS-2 into Spanish, the strategy of reverse translation of Hambleton (1996) were used. Confirmatory factor analysis (CFA) was performed with the LISREL 8.80 program with the estimation procedure robust maximum likelihood. To evaluate the differences between the setting of alternative models, differences less than or equal of .01 between values of CFI indicates practical differences (Cheung & Rensvold, 2002). Analysis of reliability (Cronbach's alpha) were performed with the program SPSS 22.0. Results The CFA showed that six factors model had a close fit: $2(687) = 1340.85$, $p < .001$; RMSEA = .08; CFI = .86; NNFI = .85. Although the factors loadings of six items were below the criterion ($> .40$). A second model in which these items were removed was tested: $2(579) = 998.44$, $p < .001$; RMSEA = .07; CFI = .90; NNFI = .90. In this second model all items load significantly ($p < .01$) with factor loadings above criteria. Phi correlations matrix between latent factors were lower than .80. Comparing the indexes of incremental fit between the two models, the results showed better fit for the second model (CFI = .03). The Cronbach's alpha coefficients of the factors were above the criterion value, except the perceived coach pressure factor. Discussion The adaptation to the Spanish spoken in Mexico of the S-MPS-2, has demonstrated adequate validity of its factorial structure, and adequate internal consistency for the factors. So can be used in the sporting context for the measurement of the six facets of perfectionism proposed by Frost and cols. (1990). However, the validity is confirmed after the elimination of six items; three of them are the same as those suggested by the results of Gotwals and cols. (2010) in the original version. DEVELOPING A SCALE TO APPRAISE REQUIRED MENTAL SKILLS FOR REFEREES

MURAKAMI, K.

Tokyo University of Science

Introduction Sports umpires, referees, and their assistants are responsible for ensuring that the competitive efforts of athletes take place within the rules of the game, and that match results are obtained fairly. Not only must referees continuously endure physical pressure, they should also be willing to psychologically endure various stressors. As the best performance cannot be expected from athletes and coaches who are under a great deal of stress, referees are, similarly, sometimes unable to demonstrate proper performance (Reilly and Eregson, 2006). One key factor in referees working to their capabilities in regard to performance is the use of appropriate mental skills. The purpose of this study, therefore, is to develop an appraisal scale for the required mental skills for referees, and to drive home the impact of mental skills on performance. Methods The statistical population of this study included all international and national referees in the fields of handball, soccer, tennis and baseball, which, according to the related federations, were 352 subjects. These subjects had arbitrated sporting events for 4 to 33 years, with a mean of 12.5 ± 8.51 years of refereeing experience. We considered 6 dimensions of mental skills based on elite referees' practical experience, and used this to create a hypothetical model of required mental skills for

referees. Results To examine the internal consistency of the items, we calculated the correlation coefficient between the summation of item scores in the scale and the rated scores in each item. A significant correlation was obtained in the range of $r = .39\text{--}.78$ for all items, which showed internal consistency. Factor analysis (principal factor solution, promax method) was employed to detect the factor structure of questionnaire items. For refereeing situations, 6 factors were derived from 24 items in the questionnaire and named as follows: emotional control, resolute attitude and look, motivation, confidence, communication, and concentration. High reliability coefficients were observed, and the validity of the structural concept reached the acceptable standard. Discussion Exploratory factor analysis of the mental skills for referees yielded a very clear factor structure. The findings of the factor analysis, together with the descriptive statistics presented for each subscale, clearly support previous studies (Weinberg and Richardson, 1990) in identifying motivation, confidence, communication, and emotional control strategies as an important feature of the qualities in a good referee. The information gathered from this work also provides insight into how we can better create training programmes for mental skills for this population. References Reilly, T. and Eregson, W. THE FACTORS AND METHODOLOGY TO BUILD UP THE FLOW STATE OF THAILAND TAEKWONDO'S ATHLETES

THAWORNWAT, S., PRACHAKUL, W.

Sports Authority of Thailand

Introduction This research is a qualitative research, aims to study realizing of flowing state, the factors and methodology to build up the flow state of Thailand Taekwondo's athletes who joined the 28th SEAGAMES at Singapore in both practical and competition state. Collected the data by using Semi - structured Interview, observation, critical incident, and questionnaire of the flow state. Methods The sample were 6 people of Thailand Taekwondo's athletes who joined the 28th SEAGAMES at Singapore, age of 18-24 years old, 5-13 years of competition experience. Analyzing data by constant comparing. Trustworthiness the data by member check, triangulation and peer debriefing. Results The result found that; 1.Score of flow state in practical state was 143, 145, 145, 130, 137, 131 points. Flow state score in competition state was 164, 161, 157, 142, 140 and 115 points (ranked from gold medal, silver medal and bronze medal) 2.Taekwondo's athletes recognized the flow state in practical state that is the practice as expected, pursued the goal, automatically, fun, practice with full performance, and has developing, for flow state in competition state is automatically play, continuously, full potentials, happy and quickly pass of time, thought controlled, confident and concentrate. 3. Factors effect to the flow state in practical state has 6 factors are practical goal, effectiveness of practical program, practical atmosphere, coach and staff, mental and physical readiness. In the other side, 6 competition state factors are automatically movement of body, concentrating to competition, self-confident, verbal form coach, thought and emotional well controlling, and good readiness preparation. 4. The method of building up of flow state in practical state has 5 methods, goal setting, mind concentrate, body readiness, mental readiness, and self-motivation. For the competition state has 6 methods are concentrating, relaxing and stress managing, imaging and warming up, thought controlling and self-encourage and building up self-confident. Discussion Result from research indicated the flow state is essential to Taekwondo's athletes to both practical and competition state, trainer and team and Taekwondo's athletes should be realized to factors of influencing flow state to meet high performance and effectiveness of practical and competition. BASIC PSYCHOLOGICAL NEEDS AS A MEDIATOR BETWEEN MINDFULNESS AND ATHLETES' WELL-BEING: A LONGITUDINAL STUDY

CHEH, L.H.

National Taiwan Sport University

Introduction Mindfulness has been conceptualized as paying sustained attention to ongoing cognitive and emotional experience with a non-judgmental and non-elaborating attitude (Kabat-Zinn, 2003). Previous studies have demonstrated mindfulness positively contribute to individual's well-being (Brown & Ryan, 2003); however, the underlying mechanism is not fully understood. Therefore, based on self-determination theory, the present research conducted a longitudinal design to investigate the mediating role of basic psychological needs in the relationship between mindfulness and athletes' well-being. Methods Time-lagged design was used to collect data during two periods to examined mediation effect. The first data collection involved 104 athletes with a mean age of 20.66 years ($SD = 1.68$). After five months later, we collected well/ill-being indicators again. The sample consisted of 104 athletes (49 male) with average sporting experience of 7.01 years ($SD = 4.15$). The athletes reported that they spent 19.76 ($SD = 5.79$) hours per week training. All participants read and signed the informed consent form indicating their ethical rights. Confidentiality and anonymity were ensured. Results The mediation analysis of basic psychological needs between mindfulness and well-beings indexes at Time 2 were conducted by PROCESS macro for SPSS using 10,000 bootstrap samples (Hayes & Preacher, 2013). Results revealed basic psychological needs mediated the relationship between mindfulness and both athletes' hedonic and eudaemonic well-being indicators. However, one exception was basic psychological needs fulfillment did not mediated the relationship between mindfulness and athlete burnout. Discussion The results correspond to the self-determination theory, which demonstrated that basic psychological needs mediated the relationship between mindfulness and athletes' well-beings. In this regard, we provide additional evidence to extend the scope of mindfulness from performance to well-being enhancement. These findings also provide important information for researcher and practitioners when they design programs which aimed at enhancing athletes' well-being. References Brown, K. W., & Ryan, R. M. AFFECTIVE RESPONSES IN MOUNTAIN HIKING - A RANDOMIZED CONTROLLED TRIAL FOCUSING ON DIFFERENCES BETWEEN INDOOR AND OUTDOOR ACTIVITY

NIEDERMEIER, M., EINWANGER, J., HARTL, A., KOPP, M.

University of Innsbruck

Introduction Affective responses during and after physical activity may predict the motivation to engage in future physical activity. Although mountain activities, such as mountain hiking, show a high prevalence in alpine regions, the main body of literature is focussing on physical activity in flat environments. However, both the physiological and the environmental conditions of mountain hiking are different than walking in flat environments. Therefore, the aims of the present study were (1) to analyse affective responses of a single bout of mountain hiking and (2) to detect possible influences of the environment on affect during this activity. **Methods** Using a within-subjects design, 47 healthy participants were randomly exposed to three different conditions in small groups: outdoor mountain hiking, indoor treadmill walking, and sedentary control situation. Each condition lasted for 3.5 hours. Assessments included the Feeling Scale (Hardy et al. 1989), Felt Arousal Scale (Svebak et al. 1985) and a mood survey (Abele-Brehm et al. 1986). Results 42 participants completed the study. Compared to the control situation, the participants showed a significant increase in affective valence ($\eta^2 p = .43$), activity ($\eta^2 p = .21$), elation ($\eta^2 p = .31$), and calmness ($\eta^2 p = .25$), and a significant decrease in fatigue ($\eta^2 p = .37$), anxiety ($\eta^2 p = .28$) after mountain hiking. Outdoor mountain hiking also showed significantly greater positive effects on affective valence ($\eta^2 p = .12$), activity ($\eta^2 p = .11$), and fatigue ($\eta^2 p = .16$) than indoor treadmill walking. **Discussion** The results indicate, that a single bout of mountain hiking elicits higher positive and lower negative affective responses compared to a sedentary control situation. These changes in affect are believed to raise motivation to maintain exercise behaviour in future situations (Williams et al. 2008). Additionally, the data suggest a synergistic effect of physical activity and being outdoors. Abele-Brehm A, Brehm W. (1986). PERSPECTIVE OF PARTICIPATION IN SPORTS AND LEISURE ACTIVITIES AS AN AFFECTING FACTOR ON HEALTHY AGING IN ADULTS WITH OTHER PSYCHOSOCIAL FACTORS

HAN, K.

Pusan National University

Introduction Healthy aging is a lifelong process of optimizing opportunities for improving and preserving physical, social and mental wellness, independence, and quality of life, as well as enhancing successful life-course transitions (Health Canada, 2004). Participation in sports and leisure activity relates to depression especially in old people and it influence on other psychosocial factors that were identified as influential factors in healthy aging. The purpose of this study is to identify the psychosocial factors influencing healthy aging and examining their socio-demographic characteristics. **Methods** More than 200 Korean adults aged between 45 and 80 years-old participated in the study. Self-reporting questionnaires were used, followed by descriptive statistics and multiple regressions as inferential statistical analyses. **Results** There were significant differences between participants' general characteristics: age, education, religion, housing, hobby, and economic status. Participant in sports and leisure activities and other psychological factors are correlated with health aging. The factors influencing healthy aging were depression, participant in sports and leisure activities, and other psychosocial factors in order. **Conclusion** As results, all individual psychosocial resources correlate to participation in sports and leisure activities. Old people strengthen and improve their psychological resources because participating in sports and leisure activities may provide them experiencing achievement, expanding their social and personal relationship, and increasing their physical health, and consequently old people have less depression leading to more vitality in life. Reference Health Canada. (2004). Workshop on healthy aging [www.hc-sc.gc.ca/seniorsaines/pubs/workshop_healthyaging/pdf/workshop1_e.pdf]. Contact franzhan@yahoo.co.kr insert authors here

OPTIMAL PHYSICAL ACTIVITY LEVEL TO PSYCHOLOGICAL WELL-BEING

RODRÍGUEZ-VILLALOBOS, J.M., DOMÍNGUEZ, M., BLANCO, H., ORNELAS, M.

AUTONOMOUS UNIVERSITY OF CHIHUAHUA

INTRODUCTION Psychological well-being has been recognized as a key factor to academic success (Osornio-Castillo, et al. 2010); however the college students are exposed to several physical and psychological stressors. One of the strategies to attend this problem is the physical activity, nevertheless there isn't clarity about the optimal intensity level to induce psychological benefits. The aim was to determine the relation between psychological well-being and physical activity level in college students, associated with academic performance. **METHODS** Participated 1,489 Mexican college students. The physical activity level was determined by IPAQ questionnaire identifying low, moderate and vigorous level. The psychological well-being was assessed by Ryff scale with six sub-scales: self-acceptance, positive relations with others, autonomy, environmental mastery, purpose in life and personal growth. Instruments were applied in computerized form. Academic performance was the school grades. **RESULTS** Students with vigorous intensity level had higher scores in self-acceptance ($P<0.003$), environmental mastery ($P<0.041$) and purpose in life scales ($p<0.001$). Autonomy scale shows lower scores ($P<0.004$) in students with low intensity. In all cases, the academic performance co-variable was significant ($p<0.01$). **DISCUSSION** Three sub-scales were related with the vigorous activity level, different to the study of Abu-Omar, R. et al. (2004) who refers moderate level. In concordance with Cerin, L. et al. (2009) who claim that vigorous level produce higher mental well-being. While autonomy scale doesn't differ between moderate and vigorous level, similar to studies of Mutrie N. (2007) and Hawker C. (2012) who found results in both intensity levels. The relation between physical activity and psychological well-being is clear; seems that vigorous level is the optimal intensity. The link between educational performance and well-being is evident, although the causality direction can't be clarified in this study. **REFERENCES** Abu-Omar, K., et al. (2004). RELATIONSHIPS BETWEEN BODY DISSATISFACTION, COGNITIVE BODY IMAGE, AUTHENTICITY, AND CONTINGENT SELF-ESTEEM FOR FEMALE ATHLETES

HARUKA, K.1, SHUNSUKE, K.1, TAKAYOSHI, K.1,2, KAZUO, O.3

Graduate school of Rikkyo University

1: GSHS-RU (Saitama, Japan), 2: RFJS-PS (DC2), 3: DSWCCH-RU (Saitama, Japan) Introduction This study investigates the body image of female athletes and shows a correlation with authenticity and contingent self-esteem. Method The subjects were 119 female university students (aged 19.8 ± 1.3 years) belonging to athletic clubs or teams and participating in sports activities at high frequencies (>5 times a week for 3 h). We have given attention to their privacy concerns and taken their consent for the investigation. The contents of the investigation were as follows: 1) personal data (age, height, weight, ideal weight, type of sports); 2) authenticity criterion (Ito and Kodama, 2005); 3) contingent self-esteem criterion (Ito and Kodama, 2006); and 4) Contour Drawing Rating (CDR) Scale (Thompson and Gray, 1995). Subjects were categorized into three groups based on the extent of body dissatisfaction (calculated by CDR results); no body, normal body, and strong body dissatisfaction. Subjects were categorized into three groups according to cognitive body image distortion: no distortion, light distortion, and obesity distortion. We analyzed the factor of variance of scores of contingent self-esteem criterion and authenticity criterion as the dependent variable. For statistical analysis, we used IBM SPSS statistics version 2.1. Results Here 16.6% subjects had cognitive body image disturbance based on the height distribution of cognitive body image disturbance. Moreover, based on the result of factor analysis of variance, scores of contingent self-esteem criterion and authenticity criterion analysis showed no significant difference between the three groups of cognitive body image distortion. For contingent self-esteem criterion and authenticity criterion analysis, there was no significant difference between the three groups of cognitive body image disturbance. Discussion This study showed that female athletes have accurate cognitive body images. This study showed that the main factor of body dissatisfaction for female athletes is not dissatisfaction as much as the desire to raise contingent self-esteem. These results suggest that contingent self-esteem and authenticity are not correlated with cognitive body image. Hereafter, correlations with other factors, such as competitive ability, competitive scores, and social support, such as relationships with friends, must be studied. Reference Masaya I, Masahiro K. RELATIONSHIPS AMONG COACHING EVALUATION, COLLECTIVE EFFICACY AND TEAM ADAPTATION OF HIGH SCHOOL BASEBALL ATHLETES

SHIMIZU, Y., MIYAZAKI, M.

International Christian University, J.F. Oberlin University

Introduction Baseball is one of the most popular sports in school club activities from elementary to college levels in Japan. The purpose of this study was to develop Coaching Evaluation Scale for Baseball Manager and Coach (CESBMC), Collective Efficacy Scale for Baseball Athletic Teams (CESBAT), Team Adaptation Scale for Baseball Athletes (TASBA) and to examine relationships among factors of CESBMC, CESBAT and TASBA. Methods The subjects of 94 athletes (mean age=16.27, SD=1.01, mean baseball experience=8.17, SD=2.23) in high school baseball teams were asked to answer a questionnaire on coaching evaluation, team adaptation and collective efficacy. The question items of the first two were developed from our preliminary survey in 2010 and those of the last derived from Collective Efficacy Scale (Kuniyoshi & Shimizu, 2009). Exploratory factor analyses and reliability analyses were conducted to develop CESBMC, CESBAT and TASBA. In order to examine relationships among CESBMC and CESBAT, TASBA, stepwise multiple regression analyses were conducted. Results The results of exploratory factor analyses identified that CESBMC has a 5-factor model with 32 items ("Psychological Support," "Understanding and Trust," "Team Building and Administration," "Friendly Attitude," "Game Analyses and Strategic Planning"), CESBAT has a 7-factor model with 28 items ("Efficacy for Practice," "Efficacy for Performance," "Efficacy for Social Support," "Efficacy for Goal Achievement," "Efficacy for Cooperation," "Efficacy for Emotional Expression," and "Efficacy for Loyalty"), and TASBA has 2-factor model with 25 items ("Team Adaptation" and "Team Maladaptation"). Reliability analyses and confirmatory factor analyses confirmed that all the scales had satisfactory Cronbach's alpha coefficient reliabilities and structural validities. Multiple regression analyses showed that "Team Building and Administration" was positively associated with CESBAT ($\beta=0.66$, $p<0.001$), "Psychological Support" was negatively associated with "Team Maladaptation" ($\beta=-0.29$, $p<0.01$), and "Understanding and Trust" was positively associated with "Team Adaptation" ($\beta=0.30$, $p<0.01$). Discussion The results of this study indicate that CESBMC, CESBAT and TASBA can be useful tools to assess team adaptation of high school baseball athletes. The findings also imply that coaches' higher awareness and team building skills enhance collective efficacy in teams and that psychological support from coaches and relationship based on trust are most likely to facilitate athletes' adaptation to their team. THE EFFECT OF 8 WEEKS OF TRAINING IN WATER, HAPPINESS AND SELF-ESTEEM OF WOMEN WITH MULTIPLE SCLEROSIS

AGHABEGLOO, M., SEDAGHATI, S., HOSSEINI, M.

Islamic Azad University - Islamshahr Branch

Introduction : The purpose of this study was to the effect of 8 weeks of training in water, life expectancy and self-esteem of women with multiple sclerosis. Todays multiple sclerosis that is suffering patient from poor movement and physical disability is increasing in the world and it is disease of the century now. Physical education has a special place in the sciences and as a complementary therapy help to many patients such as diabetes, cardiovascular disease, multiple sclerosis, arthritis and so on. For many years. Methods : Research method of this study is half-experimental . The population of this study was included woman who were diagnosed with multiple sclerosis therapy for multiple sclerosis patients tehran referred to Association , based on Morgan scale the sample size determined 30 people. The instrument for collecting the data includes two questionnaires: Oxford Happiness of Argyle et al (1989) and Coopersmith Self-Steem (1967). Validity of the questionnaires determined by 8 professors of sport management and reliability by using the cronbach's alpha coefficient that ordinarily are: 0.77, 0.72, 0.93. For the data analyzing, descriptive and inferential statistic (pearson correlation coefficient

and regression). Result : Result showed there is not a positive and significant in meaningful Happiness index before and after exercise ($p<0.05$). But there is a positive in self-steem observed . Conclusion : Water-therapy is a main factor in increasing self-steem in these patients . in other words that water-therapy and doing exercise will have a meaningful effect on self-steem .

CLUSTERS OF MENSTRUAL DISTRESS AND THEIR ASSOCIATION WITH SPORT-CONFIDENCE IN JAPANESE FEMALE COLLEGE ATHLETES

WAKUI, S.1, MACHIDA, M.2, KAMEMOTO, K.3, SATO, K.4, SAKAMAKI-SUNAGA, M.3

Juntendo University

Background Sport-confidence is an important factor for sport success; however, the association of menstruation symptoms with sport-confidence is unclear. Moreover, few studies have focused on individual differences in menstrual distress among female athletes. Purpose To clarify the relation between menstrual distress and sport-confidence, and to identify clusters of menstrual distress for different phases of the menstrual cycle (i.e., menstruation and the late follicular and luteal phases) and examine associations of these clusters with sport-confidence among Japanese female college athletes. Method Participants were 198 female college athletes, from which we collected data once per week over seven weeks. Participants completed questionnaires on demographic characteristics, the Moos Menstrual Distress Questionnaire (MDQ: Moos, 1968; 1986), and the Sport- Confidence Inventory (Vealey & Knight, 2002) Results We found no difference in sport-confidence between menstrual cycle phases. However, there were significant relationships between menstrual distress and sport- confidence. Using cluster analysis of the MDQ, we found five clusters spanning the phases of the menstrual cycle, as follows: Cluster 1, consistently low menstrual distress and high energetic arousal during a menstrual cycle (27.3% of total sample); Cluster 2, consistently high menstrual distress during a menstrual cycle (9.1%); Cluster 3, consistently low menstrual distress during a menstrual cycle (36.9%); Cluster 4, slight fluctuations in menstrual distress during a menstrual cycle (12.6%); and Cluster 5, large fluctuations in menstrual distress during a menstrual cycle (14.1%). Athletes in Cluster 5 showed greater sport-confidence during the late follicular phase than during the menstruation phase; athletes in other clusters showed no significant changes in this sport-confidence across the different phases. Conclusion Greater menstrual distress was related to lower sport-confidence. Furthermore, those with large fluctuations in menstrual distress during a menstrual cycle may experience changes in sport-confidence according to the phase. References Vealey, R. S. & Knight, B. J. (2002, September). Multidimensional sport-confidence: A conceptual and psychometric extension. THE INTERACTIVE EFFECT OF PHYSICAL FITNESS AND ALZHEIMER'S DISEASE RELATED GENOTYPE ON COGNITIVE FUNCTION IN ADOLESCENCE: AN EEG COHERENCE STUDY

WOO, M.

University of Ulsan

Purpose: The purpose of the study is to examine the difference of nonverbal intelligence and cortical networking according to physical fitness in adolescents carrying Alzheimer's disease related genotype(ApoE e4). Methods: Participants were middle school students consisting of ten high-fit and eight low-fit e4 carriers and fourteen high-fit and ten low-fit non-carriers. K-CTONI-2 was used to measure nonverbal intelligence, and cortical activation at F3, F4, C3, C4, P3, P4, T3, T4, O1, O2 has been recorded during intelligence test. Inter- and intra-hemispheric coherences were calculated to examine cortico-cortical communication. Results: There were no significant fitness, genotype main effects and fitness x genotype interaction effect on the score, accuracy and reaction time of the nonverbal intelligence test. However, the result of EEG coherence revealed that significant fitness x genotype interaction effects were observed and those effects were focused on right hemisphere pairs highly related to task-relevant visual-spatial processing. Specifically, coherence in low-fit e4 carriers was lower than high-fit e4 carriers but such difference between low and high fit group was not observed in non-carriers. Importantly, cortical networking in e4 carriers with high physical fitness was not discriminated by non-carriers. Conclusion: The results imply that carrying e4 allele appears to decrease neural efficiency 50-60 years before onset of AD but physical fitness seems to compensate the negative impact of carrying AD related genotype.

THE EFFECT OF PROGRESSIVE MUSCLE RELAXATION ON SPINAL POOL EXCITABILITY

SHIGEKI, A.

University of Kokushikan

THE EFFECT OF PROGRESSIVE MUSCLE RELAXATION ON SPINAL POOL EXCITABILITY 1: Kokushikan University Graduate School of Sport System (Tokyo, Japan) Purpose The purpose of this study was to examine the effect of Progressive muscle relaxation (PMR), on spinal motoneurone pool excitability during movement immediately after performing PMR. Methods Participants were male university students of high performance athletes ($n = 4$, mean age 21.8 years, $SD=1.0$). All subjects reported any medications they were taking and it was verified that none took any medications that affected the muscular or nervous systems. They practiced the simplified version of progressive muscle relaxation (Wolpe, 1954), daily for three weeks and assessed on the three weeks of practice. As a experimental, Before and after engaging in PMR in the left-foot phase, 20% maximal voluntary contraction (MVC) ankle dorsiflexion (6sec) and 70% MVC plantarflexion (6sec) of the right foot($\times 10$ set : motor task) was performed, and spinal motoneurone pool excitability was assessed by measuring the H-reflex of the soleus during the dorsiflexion part of the motor task. Electrical stimulation The tibial nerve was electrically stimulated with square pulses 1.0 sec in duration delivered through a constant voltage stimulus isolation unit on 70% MVC plantarflexion (6sec) of the right foot. The anode, a metal plate (5x13 cm) covered in gauze and moistened with saline, was placed on the opposite side of the leg above the patella. The stimulus intensity setup to elicit H reflexes was on average 10% of maximum M wave. Electromyographic recording Soleus EMG was recorded using disposable 10-mm Ag/AgCl electrodes 1 cm apart positioned immediately below the division of the two heads of the gastrocnemii in the midline over the soleus muscle. EMG was amplified ($\times 5$ Hz-2KHz) and digitized at 10 kHz. (AD Instruments Lab Chart v7.2.2) Results The result indicated that H-reflex amplitude value decreased during the motor task of the right foot before and after performing PMR in the left-foot phase. Conclusion Facilitatory effect on the excitability of the spinal motoneuron pool excitability was observed in movement immediately after performing PMR in the left-foot phase. Trimble and Harp(1998) reported that post-muscle activation effects on segmental reflexes reveal divergent results dependent upon the manner in which the muscle is activated. Therefore, PMR has the potential to influence the excitability of soleus motoneurons. References Wolpe, J. (1954) Reciprocal inhibition as the main

basis of psychotherapeutic effects. Archives of Neurology and Psychiatry(72): 205-226. Trimble, M.H. & Harp, S.S. Post exercise potentiation of H-reflex in humans. Med Sci Sports Exerc, 30, 933-941, 1998 Cntact akibas@kokushikan.ac.jp

THE RELATIONSHIP BETWEEN STATE ANXIETY AND COPING WITH EXTERNAL PRESSURE WHILE OFFICIATING: THE MODERATING ROLE OF MENTAL TOUGHNESS.

JOHANSEN, B.T., BJØRNESTAD, J.O., HAUGEN, T.

University of Agder

Johansen & Haugen (2013) found that Norwegian top-class referees are self-confident in their officiating and that they have coping strategies designed to deal with anxiety and stress provoked by others' aggressive behavior. Mental toughness (MT) is a widely employed concept in the context of sport and there seems to appear a general consensus that MT includes important individual characteristics related to successful performance and outcomes in sport (Sheard, Golby, & Wersch, 2009). The aim of this study was to examine the potential moderating role of MT in the relationship between state anxiety and coping strategies in officiating among Norwegian top class soccer referees. 109 soccer referees (100 males, 9 females) with a mean age 30.8 (sd = 6.98) ranked in Norwegian Premier League (NPL) and OBOS League (second league level) reported in a questionnaire their level of MT (SMTQ, Sheard et al., 2009), level of anxiety (CSAI-2, Martens et al., 1990), and their officiating behavior (Johansen & Haugen, 2013). Results revealed that somatic anxiety predicted negative perceptions of social pressure in the decision-making process ($r = .21, p < .05$), whereas cognitive anxiety did not ($r = -.15, p = .12$). When assessing the MODERATE-macro for SPSS (Hayes & Preacher, 2014), no moderating role of mental toughness was evident. Based on the preliminary analyses there are indications that soccer referees with more somatic anxiety are more disposed for anticipating external social pressure and the reason may be that they feel lack of coping strategies dealing with this pressure. Whether mental toughness among these soccer referees do not play a moderating role are still early days in concluding and our finding may be due to this specific sample of top-class soccer referees. RELATIONSHIP BETWEEN SELF-ESTEEM AND REGULAR EXERCISE IN THE JAPANESE ELEMENTARY SCHOOL CHILDREN

UCHIMARU, J., KIKUCHI, N., KUNO, K.

Sendai University

Introduction It is well known that lower physical fitness, exercise dislike and insufficient exercise in children are a serious problem for healthy growth and development of physical and mental. In particular, self-esteem is essential in exercise and sports activities. However, there are also unclear points such as the relationship of exercise habit and/or lifestyle and self-esteem in the growth and development period. Purpose The purpose of this study was to evaluate the relationship between self-esteem and regular exercise in the Japanese elementary school children. Methods This study was conducted among 3,680 children (1,805 boys, 1,875 girls), 4th-6th grade elementary school children (aged 9-12 years old), from 21 elementary schools in south district in Miyagi, Japan. All participants were asked to fill out self-report measures of habitual of exercise and self-esteem questionnaire. Self-esteem was investigated using Self-esteem Scale (Tokyo edition, 2011). This scale contains 22 items or phrases to measure individuals' worth and attitudes toward a real emotion concerning each item on a four-point Likert's scale (absolutely agree, agree, disagree, absolutely disagree) with scores of 1-4 and an average score of 1-4 points. Also, we evaluated three category of self-acceptance, that is, self-assertion and self-determination using by this scale. Participants were divided into four groups for each grade and gender from habitual of exercise questionnaire; high regular exercise (HE: more 3days/wk), middle regular exercise (ME: 1~2 days/wk), low regular exercise (LE: 1~3days/month), and no exercise (NE). And we compared self-esteem with self-acceptance, self-assertion and self-determination among four groups. Results Regardless of the gender, self-esteem of HE in each grade was higher than any other group. And, Self-acceptance, assertion and determination also tended to be higher due to the frequency of exercise habits, respectively. Self-acceptance, assertion and determination of girl in each grade were higher than that of boy. Self-esteem has become a low value with the upper grades. Conclusion Our results indicate that regular exercise would be enhanced and/or improved self-esteem in elementary school children. Further studies needed to confirm whether relate to the physical fitness level and lifestyle and self-esteem could be suggested as a new exercise intervention or clinical strategy for the health growth of children. ATTITUDE OF BASKETBALL AND BADMINTON PLAYING STUDENTS TOWARDS OBESITY

TOMAR, R.

King Fahd University of Petroleum and Minerals

Introduction Obesity is serious consideration among youth. A team game like basketball and an individual game like badminton both promote fitness. Students playing these games are often physically fit. Their attitude towards obesity assumes significance in university settings. Therefore, the present study examined the attitude of basketball and badminton playing students towards obesity. Methods Hundred eight students from King Fahd University of Petroleum and Minerals were selected as participants for the present study. All participants were enrolled in freshmen course of academic year 2012 -2013. Group one ($n = 51$) consist of basketball players and group two ($n = 57$) consists of badminton players. The attitude towards obese people scale (Allison et al 1991) was used as a tool to measure the attitude towards obesity. ATOP is tool widely used to measure the anti-fat attitude and biasness which consist of twenty items and based on likert rating scale. The ATOP score indicates the negative or positive attitude. Descriptive statistics was used to compute means and standard deviation. Independent sample t test was employed to find the significance difference between the attitudes of two groups towards obesity. The data obtained were analyzed with the help of statistical software (SPSS 16 version). The level of statistical significance was set at 0.05 levels. Results T Test revealed highly significant difference between ATOP scores for basketball ($M=58.11, SD \pm 9.25$) and badminton ($M=54.08, SD \pm 10.50$) groups; $t(106) = 2.10, p = .038$. Combined ATOP score of the two groups was ($M=55.99, SD \pm 10.09$).

Discussion Results suggest that basketball playing students are more positive in their attitude towards obesity compare to badminton playing students. Badminton playing students seems to have more anti-fat attitude towards obesity. Anti-fat bias occurs when overweight individual are negatively judged because they are assumed to possess negative traits such as being lazy, unattractive, self-indulgent (Phul and Brownell 2001). Rukavina et al 2008, also found that kinesiology undergraduates indicated anti-fat bias toward obese individuals on the lazy/motivated scale. References Allison DB, Basile VC and Yuker HE. (1991). International Journal of Eating Disorder, 10, 599 - 607. Puhl R and Brownell KD. (2001). Obes Res, 9, 788 -805. Rukavina PB, Li W and Rowell MB. (2008). Social Psychology of Education, 11, 95-112. GENDER DIFFERENCE IN ACUTE EXERCISE AND NEUROCOGNITIVE PERFORMANCE IN CHILDREN

WEN, H.J.1, WANG, C.H.1, TSAI, C.L.2

1: Tzu-Chi University (Hualien, Taiwan), 2:National Cheng-Kung University (Tainan, Taiwan).

Introduction The executive attention networks and the efficiency of inhibitory control are important in motor-skill learning in developing children. Previous studies have demonstrated that cognitive function can be improved by the physical exercise and gender differences could influence behavioral inhibitory control, with girls outperforming boys in behavioral self-control (Chen & Sang, 2002; Kochanska, Murry, & Harlan, 2000). However, there have been no proceeding studies investigating the influence of gender on the inhibitory control in children after an acute bout of moderate aerobic exercise. The present study thus examined the effects of such an exercise mode on behavioral (i.e., RT and accuracy) and electrophysiological (i.e., P3 amplitude) performance using a modified Flanker task in boys and girls. Methods Twenty healthy elementary school children were recruited and then randomly assigned into both acute exercise (AE) and seated rest (SR) sessions with a counterbalanced order. Behavioral and Event-related potentials (ERPs) performances were collected in 20 children during a modified flanker task at baseline and after either an acute bout of 20 minutes of moderate intensity aerobic exercise or a control period at least one week apart. All independent variables (e.g., accuracy rate, reaction time, and P3 amplitude) from the acute bout of moderate aerobic exercise were separately analyzed with repeated-measures ANOVA. Results The results revealed that, although the accuracy rate in congruent and incongruent conditions and the reaction times (RTs) in the congruent condition did not significantly improve after SR and AE sessions in all children, they showed significantly shorter RTs in the incongruent condition after AE when compared to SR. In terms of ERPs performance, P3 amplitude increased following AE when compared to SR in all children. However, only the boys displayed greater P3 amplitude in the incongruent condition after the acute exercise. Discussion The current findings replicate prior research reporting the beneficial effects of acute aerobic exercise on neurocognitive performances (e.g., RTs and P3 amplitudes) in children. The children could gain response-related (i.e., RTs) benefits in the higher inhibitory control (i.e., incongruent) condition. Only boys could obtain particular cognition-process-related efficiency with regard to attentional resource allocation (i.e., P3 amplitude) after acute exercise, implying that the mechanisms underlying the effects of such exercise on neural functioning may be gender dependent. Key-words: Executive function, Flanker, P3 amplitude, acute exercise, attention Supported by MOST Grant 103-2410-H-320-010 and 104-2410-H-320-009

Rehabilitation and Physiotherapy**ASSOCIATIONS BETWEEN SITTING TIME AND MUSCULOSKELETAL PAIN IN DIFFERENT BODY REGIONS AMONG WORKERS ACCORDING TO BLUE AND WHITE COLLARS**

SILVA, I.

FADEUP

Studies on the association between sitting time and musculoskeletal pain have found contrasting results. The aim of this study is investigate the association between sitting time (daily total, and occupational and leisure-time periods) and musculoskeletal pain in different body regions among workers by blue-collar and white. Methods: The sample comprised 205 workers. Musculoskeletal pain and related symptoms was assessed with the Nordic Questionnaire of Osteoarticular Symptoms, and the sitting time was assessed with IPAQ – Short Version. The association of sitting time and musculoskeletal pain and related symptoms was analyzed with logistic regression, adjusted for BMI, age, gender and Moderate to Vigorous Physical activity. Results: The white collars participants had lower level of moderate to vigorous Physical Activity than Blue collars. The participants were more likely to have less musculoskeletal pain and related symptoms in the ankles/feet with higher sitting time (odds ratio [OR] = 0.995, p = .032). Conclusion: Sitting time is negatively associated with musculoskeletal pain in the ankles/feet intensity only among white collars workers. Future studies using a prospective design with objective measures of sitting time are recommended. Our results emphasize the need of worksite interventions to prevent musculoskeletal pain and related symptoms.

INFLUENCE OF MOVEMENT SPEED ON MUSCLE SWELLING DURING STEP-UP EXERCISES IN HEALTHY YOUNG MEN

IKEZOE, T., SHOJI, M., ICHIHASHI, N.

Graduate School of Medicine, Kyoto University

Introduction It has been reported that skeletal muscle swelling immediately after training may be due to muscle architecture changes needed to generate muscle hypertrophy (Brancaccio et al, 2008; Yasuda et al, 2015). We examined muscle swelling, defined as the increase in the muscle thickness obtained from ultrasound images, immediately after step-up exercises and investigated the effects of movement speed during step-up exercises on muscle swelling in the lower extremities of healthy young men. Methods Twenty healthy young men (mean age 22.6 years) participated in this study. A step-up exercise, using a step of 30 cm, was performed at two different speeds (fast and slow). The fast speed group [1s for concentric phase, 1s for eccentric phase] performed the step-up exercise for 12 sets of 30 repetitions. The slow speed group [3s for concentric phase, 3s for eccentric phase] performed the exercise for 12 sets of 10 repetitions. Therefore, the total time of the step-up exercise was standardized to 720 s. The increase in muscle thickness immediately after the step-up exercise, was used as an index for muscle swelling. Ten muscle thicknesses in the lower limbs were examined using B-mode ultrasound imaging with an 8-MHz transducer: right rectus femoris and vastus lateralis, bilateral gluteus maximus, gluteus medius, semitendinosus, and gastrocnemius. Results Both groups (fast and slow speeds) showed significant increases in the thickness of all the examined muscles immediately after the step-up exercise. A two-way, repeated measures ANOVA using two factors — movement speed and muscle — indicated that both factors significantly affected the rate of change in the muscle thickness. The rate of change in

the muscle thickness was significantly greater in the fast speed group than in the slow speed group. The increase in muscle thickness was greatest for the vastus lateralis among the lower limbs muscles. Discussion The increases in muscle thickness on the ultrasonography images immediately after the step-up exercise indicate muscle swelling, which is caused by damage to the skeletal muscle. We found that there was a greater degree of muscle swelling in the fast speed group than in the slow speed group during the step-up exercise standardized by the total training time. This result suggests that step-up exercise at fast speeds may cause greater damage to the muscles in the lower extremities. References Brancaccio P, et al (2008). EFFECTS OF REHABILITATION IN MULTIPLE SCLEROSIS ANIMAL MODEL

YUN-HEE, S.

Kyungnam University

Introduction Multiple sclerosis (MS) is an autoimmune-mediated inflammatory disease which leads to cognitive deficit, visual disturbances, abnormal muscle tone, and impaired ambulation (Stevens et al., 2013). Rehabilitation is frequently used clinical strategies for improving or maintaining functional status (Kraft 1999; Stevens et al., 2013). However, molecular mechanism about effects of rehabilitation is poorly unknown. In this study, we investigated effect of rehabilitation in hippocampus and spinal cord on animal model with MS. **Methods** The mice (10 weeks) were randomly divided into three groups ($n = 10$ in each group): sham group, experimental autoimmune encephalomyelitis (EAE) group, and EAE-exercise group. For induction of EAE, the mice were injected with 100 µg myelin oligodendrocyte glycoprotein (MOG) 35-55 in complete Freund's adjuvant. The mice in the exercise groups were put on the treadmill to run for 30 min/day. To check motor function, we carried out rota-rod test, bridge test, step down avoidance task. We confirmed spinal cord and hippocampus by using molecular analysis. **Results** We found that EAE-exercise group showed good motor function compared with EAE group. We found that EAE-exercise group increased expression of myelin basic protein (MBP), CNPase, DCX, 5-bromo-2'-deoxyuridine (BrdU), Bcl-2, brain-derived neurotrophic factor (BDNF), and tropomyosin receptor kinase B (TrkB) than EAE group in the spinal cord and hippocampus ($p < 0.05$). However, expression of low density lipoprotein receptor-related protein1 (LRP-1), neurotrophin-3 (NT-3), bax, caspase-3, and TUNEL decreased in the EAE-exercise group than EAE group in the spinal cord and hippocampus ($p < 0.05$). **Discussion** Exercise training represents a promising behavioral approach for managing cognitive dysfunction in person with MS (Sandhoff et al., 2015). Enriched environment provides beneficial conditions to promote the mobilization of neural progenitors into demyelinating lesions (Magalon et al., 2007). We found that exercise applied to EAE animal model reduced demyelination and axonal injury in the spinal cord. As well as, it increased cell proliferation and prevented apoptosis in the hippocampus. Based on the present results, it can be suggested that rehabilitation may give beneficial effects to patients with MS by helping motor function and cognition ability. **Acknowledgement** This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Science, ICT & Future Planning[No. 2014R1A1A3052861] **References** Stevens V, Goodman K, Rough K, Kraft GH. EFFECT OF MANIPULATION AND CORRECTIVE CORE EXERCISES ON THE SPINAL DEFORMATION IN GOLFERS: A CASE STUDY

GI DUCK, P., KIM, S.J., YOON, S.D., SEONG, D.H., KIM, J.M., KIM, S.Y.

Kyungpook National University

[Purpose] As noted previously, only a few exercise programs can help correct spinal vertebral distortion and strengthen surrounding muscles in golfers. Several theory-oriented and formalized rehabilitation programs have been applied in both athletes and non-athletes. Against this background, this study examined spinal shape in two professional golfers with chronic back pain, and analyzed the effects of a 4-week regimen of semi-weekly manipulation therapy and corrective core exercises on spinal shape. **[Subjects]** Two golfers were selected as study subjects. Subject A was 43 years old, 174 cm tall, weighed 78.30 kg, had a body mass index (BMI) of 25.9 (kg/m²), and a 24-year career. Subject B was 46 years old, 171.40 cm tall, weighed 73.40 kg, had a BMI of 25.0 (kg/m²), and a 28-year career. **[Methods]** The pelvis and spinal vertebrae were corrected using the Thompson "drop" technique. Angle and force were adjusted to place the pelvis, lumbar spine, and thoracic vertebrae in neutral position. The technique was applied twice weekly after muscle massage in the back and pelvic areas. The golfers performed corrective, warmup stretching exercises, followed by squats on an unstable surface using the Togu ball. They then used a gym ball for repetitions of hip rotation, upper trunk extension, sit-ups, and pelvic anterior-posterior, pelvic left-right, and trunk flexion-extension exercises. The session ended with cycling as a cooldown exercise. Each session lasted 60 minutes. **[Results]** The difference in height was measured on the left and right sides of the pelvic bone. The pelvic tilt changed significantly in both participants after the 4-week program. **[Conclusion]** In golfers, core muscles are critical and are closely related to spinal deformation. Core strengthening and spinal correction play a pivotal role in the correction of spinal deformation.

EFFECTS OF ACCELERATION TRAINING AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION ON DYNAMIC BALANCING FUNCTIONS

YOON, S.D., SEONG, D.H., KIM, J.M., PARK, G.D., KIM, S.J.

Keimyung College Unversty

[Purpose] The present study aimed to investigate whether the effects of rehabilitation exercise performed after anterior cruciate ligament reconstruction on dynamic balancing functions differ between males and females. **[Subjects]** Eighteen subjects aged between 20–30 years enrolled in this study. The ages did not significantly differ between the males and females. **[Methods]** The rehabilitation exercise program was performed three times per week for 12 weeks (3 months), and was initiated immediately after anterior cruciate ligament reconstruction. Thereafter, the patients visited the hospital once per week to perform rehabilitation exercise during weeks 12–24 (3–6 months), and education on self-exercise and assessments were conducted during the visits. Self-exercise was performed two times per week according to the determined program. **[Results]** The extension active joint position sense, extension passive joint position sense, and flexion passive joint position sense of the affected and unaffected knees did not show any interaction effects between the measurement periods or between the groups. In the case of the affected knee, the results of two-way repeated-measures analysis of variance

showed no significant difference between the measurement periods or between the groups; moreover, no interaction effects were observed between the measurement periods or between the groups. In the case of the unaffected knee, although no significant difference was observed between the measurement periods, significant differences were observed between the groups. [Conclusion] In conclusion, this study revealed that most knee rehabilitation exercise training programs can be applied to both genders during the recovery period after ACL reconstruction, except for the knee rotational feedback/feedforward function exercise that may exhibit different effects based on the gender.

OUTCOMES FOLLOWING THE INTERVENTION OF THE MULTIDISCIPLINARY APPROACH FOR A PATIENT WITH SNAPPING HIP SYNDROME IN TAIWAN: A CASE REPORT

HSU, C.

Cheng Ching Hospital

Introduction : Snapping hip syndrome was the common problem of in the hip joint. The imbalance tension of soft tissue around the hip joint caused the audible snapping or popping noise as the hip moved from flexion to extension. It also caused increased stress in the joint and produced the uncomfortable symptom. Pain relief and soft tissue stretch were very important principles in conservative management. The purpose of this study was to describe the outcomes from the multidisciplinary approach for a patient with snapping hip syndrome in Taiwan. Methods: A 40-year-old female presented the pain over R't hip joint. She also complained that she heard the popping sound over R't hip joint when she walked. The sound was more obvious in the mid-stance phase in the gait cycle. The X ray finding showed that no abnormal sign was noted. The examination of standing posture showed that sway back posture was noted. No limitation of range of motion in the hip joint was found. R't sacroiliac joint hypomobility was examined. Treatment consisted of the mobilization for R't sacroiliac joint. The training of core muscle of the low back corrected the standing posture. Finally, the strengthening exercise of hip joint was instructed especially in deep hip external rotators. This case accepted 8 treatment visits over 4 weeks. Results: The pain scale and the scores of Iowa functional hip evaluation showed significant improvement. The pain scale decreased from 3 to 0. The scores of Iowa functional hip evaluation improved from 78 to 89 after treatment. She also responded that the popping sound was not obvious when she walked. Discussion: The sacroiliac joint mobilization improved the alignment of the pelvis and decreased the abnormal stress in the joint. In addition, the core muscle training provided the stability of low back and maintained the ideal posture. The strengthening exercise of the deep hip external rotators improved the stability of the hip joint. The contraction of the deep external rotators provided the motor control of femur head to the acetabulum in weight bearing phase of gait cycle. Appropriate alignment of lower quarter and the stability of the hip improved the snapping hip syndrome. Reference Konczak CR, Ames R. EFFECTS OF PROGRESSIVE RESISTANCE EXERCISE ON BODY COMPOSITION AND PHYSICAL FUNCTION IN ELDERLY FEMALE ADULTS WITH SARCOPENIC OBESITY_A RANDOMIZED CONTROLLED TRIAL

CHUN DE, L.

Taipei Medical University – Shuang Ho Hospital, Ministry of Health and Welfare

Background: Obesity is associated with an increased risk of knee osteoarthritis (KOA), which had been addressed to higher fat mass and lower lean muscle mass. The incidence of receiving a total knee replacement (TKR) among obese patients increased in recent years. The limited functional mobility after TKR, which had been addressed to the deficits of muscle function and balance ability, can be improved by postoperative rehabilitation. However, it was noted that obesity exerted negative impacts on leg muscle function and postural balance control. Furthermore, it remains unclear whether post-TKR rehabilitation improves the postoperative body composition of obese patient with KOA. Purpose: To identify the training effects of postoperative rehabilitation, using elastic resistance exercise combined with balance training, on body composition of obese patients with KOA after TKR; and the relationship between changes of body composition followed post-TKR active rehabilitation and outcomes of functional mobility. Methods: Eligible participants who are overweight and obese with a body mass index $\geq 24 \text{ kg/m}^2$, older than 45 years old and received a primary TKR were randomly assigned to either experimental group or control group. The experimental group received elastic resistance exercise combined with balance training 3 times a week for a total of 12 weeks, while the control group received only functional training in each admission. All outcome measures, including analysis of body composition using dual energy X-ray absorptiometry and bioelectrical impedance method, distance of functional forward reach, duration of single leg stance, timed sit-to-stand test, timed up-and-down stair test, timed 10-m walk, timed up-and-go test, and the Western Ontario and McMaster Universities Osteoarthritis Index score, and SF12, will be collected before rehabilitation, at the end of rehabilitation and 3 months after the end of rehabilitation. Results: Statistically significant improvement of all measures was observed in both experimental group and control group after intervention ($p < 0.001$). Study group got significant improvement ($p < 0.001$) for all measures over control group after ANCOVA with the pre-test of both groups as the covariate. Conclusion: Postoperative rehabilitation with a complex exercise regime exerts benefits on function outcome in obese patients KOA after TKR. Based on the fact that obesity is a risk of post-TKR function outcome and the need for obese patients with KOA to receive a TKR is gradually growing, further study should identify the training effects on body composition of obese patients with KOA after TKR. It is also important to identify the relationship between changes of body composition and outcomes of functional mobility in obese patients with KOA followed post-TKR active rehabilitation, which will help clinicians to develop post-TKR intervention models specified to obese subgroup in KOA population after TKR and enhancing the function outcome.

LOWER LIMBS STRENGTH, BALANCE, MOBILITY AND RISK OF FALLING IN COMMUNITY-DWELLING OLDER ADULTS

FERNANDES, B., TOMÁS, M.T., QUIRINO, D.

Higher School of Health Technology of Lisbon, ESTeSL – IPL (Lisbon, Portugal), CSM – AAPHSM (Loures, Portugal)

INTRODUCTION During the last decades there has been a rapid ageing of the Portuguese population. The ageing process involves several changes namely a decreasing in lower limbs strength, mobility and balance which contributes to increase the risk of falling and the likelihood to suffer fractures or traumatic brain injuries among other injuries. Physiotherapy can develop an important intervention in identifying the factors that potentiate the risk of falling and can provide strategies to prevent or reverse this risk. The purpose of this study was to characterise the risk of falling and related factors in a sample of Portuguese community-dwelling older adults. METHODS Cross-sectional study. 74 subjects participated in the study (50 women, 24 men), aged 65-97 years, apparently healthy, independent and living in the community. The following tests were used: to assess lower limbs strength the 30s chair stand test; 8-foot up and go test to assess

mobility and the Berg Balance Scale (BBS) to assess balance. The risk of falling was determined based on BBS. RESULTS The results of our study showed that for 30s chair stand test the mean value was 11 repetitions and for 8-foot up and go test was 8.63 seconds. For BBS the median was 53 points. 36.5% of the participants reported at least one fall during the previous year. Negative correlations have been found between 8-foot up and go test and 30s chair stand test ($R=0.664$; $p=0.00$) and between 8-foot up and go test and BBS ($R=0.653$; $p=0.00$). A weak positive correlation was also found between 30s chair stand test and BBS ($R=0.475$; $p=0.00$). DISCUSSION The results of the 8-foot up and go test (>8.5 seconds) indicate that this population was at risk of falling (Rose et al, 2002). In addition, BBS scores showed that the risk of falling was 11% (Muir et al, 2008). Lower limbs strength was decreased compared with reference values for Portuguese population (Marques et al, 2013). Assessment of these factors seems to be recommended in order to develop and implement strategies directed to increase lower limbs strength, balance and mobility and decrease the risk of falling. THE EFFECTS OF KINESIO TAPING IN PROPIROCEPTION FOR PITCHERS WITH GLENOHUMERAL INTERNAL ROTATION DEFICIT

LO, C.L.1, CHEN, C.N.2, CHANG, H.Y.2,3

1: Department of Physical Medicine, Cheng Ching General Hospital (Taichung, Taiwan), 2: School of Physical Therapy, Chung Shan Medical University (Taichung, Taiwan), 3: Room of Physical Therapy, Chung

Introduction Throwing movement that performed by pitchers is a kind of overhead sports. According to previous studies, repeated throwing often resulted in increased external rotation and decreased external rotation of pitchers' shoulder and anterior capsule laxity which may cause shoulder problems such as impingement, instability, labrum lesion etc. Proper movement control by improving proprioceptive sense has become an important issue for pitchers to prevent injuries. Therefore, the purpose of this study was to exam the effects of Kinesio taping in shoulder proprioception among pitchers with glenohumeral internal rotation deficit. Methods Twenty-one Right handed male pitchers (age from 18 to 22) with right shoulder internal rotation limitation and regular training were recruited and randomly relocateed to control ($n=10$) and Kinesio taping ($n=11$) group (KT group). Participants in KT group were taped by using Kinesio tape which aimed to improve shoulder internal rotation limitation. All subjects received joint position sense error (JPS error) test and force sense error (FS error) test before and after taping to detect proprioceptive difference between groups. Results Kinesio taping showed no significant effect in joint position sense and force sense for pitchers with glenohumeral internal rotation deficit ($p>.05$). Discussion The findings of this study indicated that a superficial stimulation e.g. Kinesio taping may not enhance proprioception for pitchers with glenohumeral internal rotation deficit. A possible explanation is that proprioception is a complex sensory system, the receptors scattered in cutaneous, muscle, capsule etc., but taping is only applied on skin that may not have enough stimulation for proprioception. THE EFFECT OF AROMATHERAPY ON DELAYED ONSET MUSCLE SORENESS

WU, C.L., CHENG, Y.N., CHIU, C.H., HONG, K.H.

National Chung Hsing University

Delayed onset muscle soreness describes muscle pain and tenderness that typically develop several hours post-exercise and consist of predominantly eccentric muscle actions, especially if the exercise is unfamiliar. The purpose of this study was to examine the effects of plain carrier oil massage and aromatic massage on delayed onset muscle soreness using a within-subjects cross-over design. Nine healthy young males performed an exercise protocol designed to induce delayed onset muscle soreness on their non-dominant arms on 3 separate occasions; each occasion was separated by at least two weeks. The protocol consisted of 3 sets of 10 maximal eccentric repetitions of the elbow flexors exerting isokinetic dynamometry. Subjects were randomly assigned to a carrier oil massage group, aromatic massage group or control group and received treatments 20 minutes post-exercise, 24 and 48 h post-exercise. Creatine kinase (CK), lactate dehydrogenase (LDH), myoglobin (Mb), range of motion (ROM), limb girth and muscle soreness index were measured pre, 20 minutes post, 24, 48 and 72 h post-exercise. Significant time effects were observed for CK, Mb, ROM, limb girth and muscle soreness index ($P < .05$). There were no significant differences between treatments. Compared with control group, carrier oil massage and aromatic massage are also ineffective in reducing CK, LDH, Mb or muscle soreness index. In addition, no significant effects of carrier oil massage and aromatic massage on recovery of ROM or limb girth were found within 72 hours. Conclusion: both carrier oil massage and aromatic massage have no significant effect on the symptoms of delayed onset muscle soreness.

INFLUENCE OF HIP ABDUCTOR FATIGUE ON TRUNK AND LOWER EXTREMITY MECHANICS DURING SINGLE-LEG LAND-ING IN FEMALES

TSUKAGOSHI, R., NISHIOKA, S., NAGAOKA, S., SAKITANI, S.

Hyogo University of Health Sciences

Introduction Because hip abductor strength is associated with lower extremity mechanics, especially knee adduction angle during weight-bearing activities, weakness of hip abductor is thought to increase the risk of anterior cruciate ligament (ACL) injuries (Jacobs CA, 2005; Chaudhari AM, 2006). However, there are a few studies that have investigated the influence of reduced hip abductor strength on trunk and lower extremity mechanics during single-leg landing in the experimental setting. The present study aimed to examine the changes in trunk and lower extremity mechanics during single-leg landing occurring due to hip abductor fatigue. Methods Fifteen young females participated (age, 21.5 ± 0.7 years). Single-leg landing mechanics was examined in the subjects before and after a hip abductor fatigue protocol. This protocol comprised repetitive isokinetic hip abduction using a dynamometer. During this protocol, hip abduction was repeated until the hip abduction torque decreased to less than 50% of the maximal strength, 5 times in a row. A 3-dimensional motion capture system with 8 cameras and a force plate were used to record a single-leg landing. Reflective markers were attached to the trunk, pelvis, and lower extremity of the subjects based on the Vicon plug-in-gait marker placement protocol. Each subject performed

3 single-leg landings from a 30-cm height before and immediately after the hip abductor fatigue protocol. The maximal value of trunk, hip, and knee kinematics and kinetics, and vertical ground reaction force during the initial contact to maximal knee flexion were analyzed. A paired t test was performed to compare the pre- to post-hip abductor fatigue protocols for each dependent variable of interest. Results The maximal hip abductor strength decreased by 27% due to the hip abductor fatigue protocol. The peak external hip adduction moment decreased and peak trunk ipsilateral bending angle increased during the landing trials after the hip abductor fatigue protocol. No other significant kinematic and kinetic changes were observed between the pre- and post-hip abductor fatigue protocols. Discussion Increase in trunk ipsilateral bending due to hip abductor fatigue transfers the center of gravity of the upper body close to the hip joint, which might contribute to decreasing the external hip adduction moment and preventing an increase in the knee abduction angle. In an actual sports situation, it is thought that the risk of ACL injury associated with knee abduction increases if compensatory motion such as trunk lateral bending is restricted. THE IMPACT OF COLD WATER IMMERSION ON BRAIN DERIVED FACTOR AND ABILITY TO CONCENTRATE AMONG HIGH TRAINED ATHLETES.

JAWORSKA, J.1, LASKOWSKI, R.2, DZEDZEJ, A.1, MICIELSKA, K.1, ANTOSIEWICZ, J.3, ZIEMANN, E.1

1,2Gdansk University of Physical Education and Sport, 3Medical University of Gdansk Poland

Introduction Cold water immersion (CWI) is applied in order to support regeneration after training. The effect of this procedure on "mental" recovery, however, has not been studied. Thus we investigated the impact of CWI on ability to concentrate after a high-intensity randori judo training (RT). We hypothesized, that the improvement in mental concentration will be associated with changes in irisin and BDNF level. Basing on the observation that the axis between irisin and BDNF is present in response to exercise (Wrann, White et al. 2013), we assumed that the coldness will be additional factor stimulating irisin release. Methods Fourteen professional judoists performed a randori training (RT) followed by a coldness exposure-supported recovery or a simple rest in case of the cold water treatment (CWG; 8oC, 4-min immersion) and control group (CG), respectively. Group assignment was a randomized controlled crossover. After one week the groups swapped and repeated the whole experiment. Each time, after 1h of recovery the ability to concentrate was tested using the Grid Exercise Test by Harris. Blood samples were collected at rest, 1h and 12h after training. Results The recovery supported by CWI did not significantly influence the scores in Grid Exercise Test. Interestingly, CWI induced the anti-inflammatory response (increase IL-10), however, the effect dissipated within 12h. The values of BDNF recorded 1h after training and CWI slightly dropped in comparison to the baseline (9.20 ± 3.2 vs 8.46 ± 2.8 ng·mL $^{-1}$). Its concentration was reduced among 12h after RT (5.07 ± 3.0 ng·mL $^{-1}$). The similar tendency was observed in control group, however the drop was much more pronounced (10.8 ± 3.02 at rest vs 4.09 ± 1.9 12h after RT, $p < 0.05$). Directly after training and CWI significant correlation between BDNF and HSP27 was noted ($r = 0.87$, $p < 0.05$). The high-intensity randori judo training caused the rise of blood HSP27, but CWI treatment had any effect on it. Discussion Obtained results did not confirm our assumption that CWI improves the ability to concentrate. Moreover, despite the exhausting exercise, we did not observe "mental" fatigue. CWI slightly changed the irisin concentration but significantly diminished the BDNF level. Interestingly in CWI, those athletes, who were characterized by an elevated concentration of HSP27 after the RT had the highest concentration of BDNF. In conclusion these data indicate that although the lack of influence of CWI was on ability to concentrate, this procedure may have positive impact on proteins responsible for "mental" fatigue. NAVICULAR DROP IS ASSOCIATED WITH FLEXOR HALLUCIS BREVIS THICKNESS IN COMMUNITY-DWELLING OLDER ADULTS

FUKUMOTO, Y., ASAI, T., ICHIKAWA, M., KUSUMI, H., OKA, T., KUBO, H., KASUYA, A., NAGAI, K., TSUKAGOSHI, R., NAKA, T. Kobe Gakuin University

Introduction Excessive foot pronation and flat foot are common foot problems in older adults (Pita-Fernández et al., 2015). Generally, navicular drop is associated with these foot problems, so its mechanism should be clarified to prevent the progression. It is thought that intrinsic foot muscles may play an important role in the mechanism, but its role is poorly understood. The purpose of the present study was to investigate the relationship between the thickness of intrinsic foot muscles and navicular drop in older adults. Method Ninety-three adults from the community aged over 65 participated in the present study. The navicular height was measured on the right foot with three-dimensional foot scanner at sitting and standing positions. Using this data, the navicular drop was calculated as the change ratio in navicular height from sitting to standing position. The thickness in the potential contributing intrinsic foot muscles, which are flexor hallucis brevis and flexor digitorum brevis were measured on the right foot using ultrasonography, as previously described (Mickle et al., 2013). The multi-regression models were applied to examine the navicular height at sitting and standing positions, and the navicular drop in relation to the thickness of both intrinsic foot muscles. Results The flexor hallucis brevis thickness was significantly associated with the navicular drop and the navicular height at standing position but not at sitting position after adjusting for potential confounders. On the other hand, the flexor digitorum brevis thickness was not significantly associated with the navicular drop in the all multiple regression models. Discussion Our results indicate that the function of flexor hallucis brevis may have a strong link to navicular drop in foot in older adults. Thus, flexor hallucis brevis may have an important role for preventing excessive foot pronation or flat foot. THE INTERDISCIPLINARY BETWEEN OCCUPATIONAL THERAPY AND PHYSICAL EDUCATION

OLIVEIRA, T., MAGALHÃES, G., SOUZA, S., BARROS, J., GALLASSI, A., SILVA, A.

University of Brasília; Cardiology Institute of the District Federal; Federal University of Rio Grande do Norte

Occupational therapy (OT) works with human life and acts in daily life and quality of life of the subject as well as Physical Education (EF), has human life as a performance target and make use of various tools. Among the tools the Activities of Daily Living (ADLs) deals with the individual-activity-environment, and the way in which the subject meets their basic and personal needs and how to organize their daily routine (sanitize, dress, food). Moreover, it is relevant to mention the psychomotor development with the technical working autonomy and independence of the subject, which directly affects the quality of life. You are talking about two professions united by one work object:

human life. Because it is something unique, each person is unique, this jobs created to care for human life. It is making you reach satisfaction and quality of life, as are professionals who develop the human's science health and all your senses. Therefore, the OT and PE relate when they treat the human considering its peculiarities, economic factors, psychological, social, religious, cultural and especially biological / physical. Thus, from the link, they are professionals who build on their potential great skills. Specifically, the rehabilitation, the OT has the particularity of activity analysis as a tool, because from it you can categorize with purpose and method which must be submitted to greater objectivity and quality, to the subject. Considering rehabilitation as the improved performance of the functional capabilities of the human body by permanent or temporary reasons is unable to carry out their activities, among them, ADLs, work and leisure, we have that is the health care that instrumentalizes relationship / interaction of the individual and their role / environment (1). With everything, it can be concluded that the OT and the PE should work as a team, because they have the same object of work and both of them use of additional working tools. Like this, there are immeasurable gains for people who enjoy and / or need these professionals. Thus, as to the actual advancement of professions, since the more the sciences communicate higher are launched flights for evidence-based practice. Reference: 1. Neistadt ME, Crepeau EB. Occupational Therapy. Traduzido por Willard & Spackman. Terapia Ocupacional. Nona edição, Rio de Janeiro, 2002.

DEVELOPMENT OF AIR INJECTABLE HARNESS FOR IMPROVED COMFORT AND LOADING PRESSURE DISTRIBUTION

KWON, N.

Korea Institute of Industrial Technology

1. Introduction The harness supports body primarily for fall prevention and it typically consists of a hip belt and shoulder straps with only minimal padding. They are 'one size fits all' and not truly customizable to fit the individual body. Therefore, the need for a more comfortable harness has been indicated through previous studies because current harnesses have many problems such as activity restriction and insufficient support of wearer's body. In the development of the harnesses for performance, entertainment and rehabilitation, the distribution of the load pressure, wearing sensation and convenience are an important research theme. The object of this study is to develop and evaluate a more comfortable harness. It was hypothesized that advanced design, using the air injectable pads would reduce loading forces. 2. Methods Three types of harnesses were newly designed based on generally used harness. In the new-type of harnesses, multi-layer air injectable pads developed using hollow fibers and the 3D spacer fabrics were applied. The size, number and position of the pads can be chosen depending on the type of the harness. The load pressure exerted from the harness to the body was measured by sensor strips (Pliance sensor S2148, Novel GmbH.; Sensing area 160x40mm², Pressure range 15~600kPa, Number of sensors 64ea) which were placed under both sides of wearer's thigh. A comparison of force and peak pressure between the different type of the harnesses with or without air injectable pads was made. 3. Results and Discussion The mean pressure and peak pressure were significantly reduced with the air injectable pads inside the harness. Loading pressure of the new -type harness decreased considerably when the air injectable pads were placed on thigh and abdomen. Peak pressure reduced by 55% and mean pressure reduced by 12% with the air injectable pads. The sensor loading area increased because the air injectable pads properly fitted to the body shape. 4. Conclusions Distribution of the load pressure exerted from the harness is the decisive factor that has great impact to the conventional harness. The general harness appears too much loading on hip belt and shoulder straps and this can become uncomfortable, and should make every endeavor to reduce discomfort and potentially damaging forces. In this study air injectable pads were applied to solve the fitting problems of existing harnesses. The air injectable pads individually fit along the wearer's body by multi-layer structure consisted of polyester foam and 3D spacer fabric at first. Additionally, injection of air can provide enough cushioning and support body. Therefore the pain by pressure concentration can be reduced and improved comfortable wearing sensation. It is expected that ergonomic design of the harness will possible to ensure comfort and support to the wearer's body. 5. References Novotny, Sara C., et al. RESEARCH IN THE FIELD OF PHYSIOTHERAPY

BUNGARTZ, G.

Hochschule Fresenius, University of Applied Sciences

Introduction The field of Physiotherapy (PT) has gone through major changes in the recent years. Some countries followed Australia and adopted direct access (DA) others allow DA only in a private setting and finally, other countries do not allow DA at all (1, 2). Although experience appears to show an overall benefit for patients and health care systems in terms of care and cost effectiveness (3, 4) intense discussions about DA are still enduring. This study provides an important new argument to the debate by measuring the productivity of science and research based on the output of research papers in PT and related fields. Methods The database SJR (5) was used to extract the amount of globally published papers in PT, Sport Science and other disciplines from 1999 to 2014. The rate of citations per article was analyzed and the contribution of over 10 western countries evaluated and compared. Results In PT related research the rate of published papers steadily increased from approximately 4000 to 12000 and in "Sport Science" from 7000 to 16000 from 1999 to 2014. Thus, these fields outnumber medical disciplines and importantly increase at a faster pace. Similar results were obtained regarding the impact evaluated by number of citations each article generated. This hints overall to a large innovative potential within PT and Sport Science, respectively. Remarkably, corresponding numbers of "Molecular Biology" remained almost unchanged from 1999 to 2005 to then increase almost exponentially. These data demonstrate that molecular biology is representing a growing part within the life sciences and will most likely impact PT related research progressively. The country comparison revealed that in terms of quantity and impact countries with DA, such as Australia, Sweden and the Netherlands outperformed others with limited DA, such as, Austria, Spain and Germany manifold. Evaluations of other disciplines suggest that the low contribution appears to be specific for the field of PT. Whether the level of college education and status of DA are causative for these differences remains speculative. Discussion The data imply that the growing body of knowledge within PT necessitates highly trained professionals to maintain clinical care. The data support the hypothesis that countries allowing DA outperform countries still banning DA in PT related research and advocate, in line with the WCPT, the introduction of DA. Hence, these data provide helpful arguments in a complex discussion about the status of DA and physiotherapist education. References 1. Galley et al. 1977 2. Bury et al. 2013 3. CAN MCCONNELL TAPING OR SERF STRAP AFFECT PLANTAR LOADING PATTERNS OF THE REARFOOT IN ADULTS DURING WALKING AND JOGGING?

POOMSALOOD, S., HAMBLY, K.

University of Kent

Introduction Patellofemoral pain syndrome (PFPS) is a common pathology of the knee accounting for 30% of all knee injuries (Anloague, 2011) and can be found in both athletic and nonathletic population (Kowall et al., 1996). There are limited research studies assessing effects of McConnell taping (medial patellar taping) and the stability through external rotation of the femur (SERF) strap (Don Joy Orthopedics Inc, Vista, CA) on rearfoot plantar loading patterns. The aim of this study was to investigate effects of McConnell taping and SERF strap, which are treatment methods for PFPS, on rearfoot plantar loading patterns in healthy adults during walking and jogging. **Methods** Twenty-three participants (12 males and 11 females, age: 26.52(6.43) years) were recruited in the study. All participants were tested in 2 functional activities which were walking and jogging under 3 conditions: 1) no tape, 2) McConnell taping, and 3) SERF strap randomly. Data (maximum pressure of medial (MH) and lateral heel (LH), contact area of MH and LH, initial heel contact, foot axis angle, and center of pressure (COP)) were collected using a 2 m footscan pressure plate (RSscan International, Belgium). During the study, each participant was instructed to walk and jog on the pressure plate at their own natural pace. **Results** There was a statistically significant difference of maximum pressure of LH during walking ($p = 0.011$) which the SERF strap condition had higher maximum pressure than the no-tape condition (SERF: 7.46(2.14) N/cm²; no tape: 7.01(1.23) N/cm², $p = 0.006$). However, significant differences of other variables were not found. **Discussion** Excessive rearfoot pronation is frequently associated with PFPS development (Barton et al., 2011). In the present study, maximum pressure of LH while wearing the SERF strap was significantly higher than one of LH with the no-tape condition ($p = 0.011$) during walking. The possible reason was that the SERF strap pulled the femur and the tibia laterally so it reduced pronation of the foot and the lateral loading of the rearfoot increased. The further study should focus on the SERF strap and McConnell taping on plantar pressure in patients with PFPS compared to healthy people. References Anloague PA. (2011). J Appl Res, 11(2), 97-104. Kowall MG, Kolk G, Nuber GW, Cassisi JE, Stern SH. (1996). Am J Sports Med, 24(1), 61-66. Barton CJ, Levinger P, Webster KE, Menz HB. (2011). Gait Posture, 33, 286-291. Contact sp620@kent.ac.uk

STEPPING EXERCISE ON PHYSICAL PERFORMANCE IN THAI ELDERLY: A RANDOMIZED CONTROLLED TRIAL

JANYACHAROEN, T., SIRIJARIYAWAT, K., NITHIATHAWANON, T., PAMORN, P., AUVICHAYAPAT, P., SAWANYAWISUTH, K.

Research Center in Back, Neck and Other Joint Pain and Human Performance, KhonKaen University

Introduction Elderly people are increasing continuously in several countries. Anatomy and physiology of the elderly may change and reduce physical performance. This study was investigated the effect of stepping exercise and physical performances in Thai elderly. **Methods** Forty-two subjects were divided into two groups. The control group ($n=21$) did not undergo stepping exercise but received health education and remained their activity daily livings. The experimental group ($n= 21$) received stepping exercise program for 3 times per week, 60 min per time for 8 weeks. All subjects were measured baseline characteristic and physical performance before and immediately after the program. **Results** Six minute walk test (6MWT), functional reach test (FRT), time up and go test (TUGT), and five times sit to stand test (FTSST) in the control group were not significantly different after program. In contrast, the subjects in the experimental group showed significantly increased of the scores of 6MWT ($p<0.001$), FRT ($p=0.004$) and also showed significantly decreased of the scores of TUGT ($p<0.001$) and FTSST ($p<0.001$). **Discussion** This study showed that stepping exercise improves physical performances (6MWT, TUGT, and FRT) in healthy elderly subjects with a shorter period of intervention at 8 weeks. Similarly to other aerobic exercises, 6MWT was significantly increased from the baseline after stepping exercise and also significantly different from the control subjects. Female subjects with average age of 65 had longer 6WMT with a 6-week course of Thai dance compared with control subjects (416 vs 345 m), while COPD patients also had longer walking distance after training exercise (381 to 487 m) (Janyacharoen et al., 2011; Janyacharoen et al., 2013). These 6MWT improvements were explained by aerobic exercise in the elderly and also COPD patients (Borghi et al., 2009). At the end of study, both TUGT and FRT in control subjects were significantly worse than the baseline. These data indicated that mobility and stability were improved by stepping exercise and worsen without exercise in the duration of 8 weeks. We had unexpected results of the non significant improvement of FTSST. This may not conclude that stepping exercise did not improve physical fitness of lower extremities because the improvement had a trend of improvement when compared with the control subjects (p value < 0.08). Further studies with longer study duration may be needed. In conclusion, stepping exercise is appropriate for the healthy elderly subjects. Physical performance significantly improved after the 8 week-course of stepping exercise. References Janyacharoen T, Chaichanawongsa J, Namsiri S, Thongduang Y, Arayawichanond P. (2009). VALIDITY AND RELIABILITY OF THE FRENCH TRANSLATION OF THE PATIENT-RATED TENNIS ELBOW EVALUATION QUESTIONNAIRE

KAUX, J.F., DELVAUX, F., SCHAUSS, J., DEMOULIN, C., LOCQUET, M., BUCKINX, F., BEAUDART, C., VAN BEVEREN, J., CROISIER, J.L., FORTHOMME, B., BRUYÈRE, O.

University of Liège

Background: The lateral elbow tendinopathy is a common injury in tennis players and physical workers. The Patient-Rated Tennis Elbow Evaluation (PRTEE) questionnaire was created to measure pain and functional disabilities specifically reported in patient with lateral epicondylitis (tennis elbow). Developed in English, this questionnaire has since then been translated into several languages but not in French. **Objectives:** The aims of the study were to translate and cross-culturally adapt the PRTEE questionnaire into French and to evaluate the reliability and validity of this new version of the questionnaire (PRTEE-F). **Methods:** The PRTEE was cross-culturally adapted into French according to the international guidelines. To assess the reliability and validity of the PRTEE-F, 115 participants filled in the PRTEE-F twice, and the Disabilities of Arm, Shoulder and Hand questionnaire (DASH) and the Short Form Health Survey (SF-36) once. Internal consistency (with Cronbach's alpha), test-retest reliability (with intra-class correlation (ICC)), convergent and divergent validity (by calculating the Spearman's correlation coefficients with the DASH and some sub scales of the SF-36, respectively) were assessed. **Results:** The PRTEE was translated in French without problem. PRTEE-F showed a good test-retest reliability for the overall score (ICC 0.83) and for each items (ICC 0.71-0.9) and a high internal consistency (Cronbach's alpha = 0.98). The correlation analyses revealed high correlation coefficients between PRTEE-F and DASH (good convergent validity) and, as expected, a low or moderate correlations with the divergent subscales of the

SF-36 (discriminant validity). There was no floor or ceiling effect. Conclusions: The PRTEE questionnaire was successfully cross-culturally adapted into French the PRTEE-F is reliable and valid for evaluating the French-speaking patient with lateral elbow tendinopathy.

THE ASSOCIATION BETWEEN LOWER LIMB FORCE GENERATION AND STRENGTH PRODUCTION IN ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTED PATIENTS

GHULAM, H., HERRINGTON, L., COMFORT, P., JONES, R.

University of Salford

Background: Muscular power has been considered as one of the essential elements of dynamic athletic performance, especially in sporting occasions that involve high force generation in a short period of time (1). Moreover, Lower extremity muscular strength is often assumed to reflect and affect overall performance. One example of this is that there is a positive relationship between isokinetic muscle strength and hop performance during single-leg hop tests (2). However, there is lack of literature exploring the relationship of lower limb force generation with muscles strength tests which might have a role in overall performance. This will inform the specialists about what are the suitable tests should be used to explain lower limb function. Therefore, the aim of this study is to investigate the association between lower limb force generation tests using FT 700 and knee muscles strength test (quadriceps & hamstring) using Bidex System 4 in ACL patients. **Design & Setting:** A correlation study undertaken in the Human Performance Laboratory at the University of Salford. **Participants:** 16 ACL reconstructed (6-9 post-operative) patients, 9 males and 7 females, were recruited (age 22.31 ± 3.37 years; height 179 ± 9.71 cm; and mass 78.31 ± 11.83 kg). **Interventions:** Two different tests have been undertaken on both legs (injured & non-injured): 1-Force tests: include ten consecutive vertical jumps and the unilateral stance isometric mid-thigh pull (IMTP). 2-Isokinetic muscle strength tests: of quadriceps and hamstring muscle testing. All of strength tests were performed in concentric muscle action only. **Main Outcome Measurements:** 1-Force tests: six variables (in concentric phase) for ten jumps test which were: maximum rate of force development (RFD), peak force, peak power, peak velocity, time to peak force, and time to peak power. While six other variables (in concentric phase) for IMTP test which were: maximum RFD, peak force, impulse 0-100ms, impulse 0-200ms, impulse 0-250ms, and impulse 0-300ms. All force tests were undertaken using FT 700. 2-Isokinetic muscle strength tests: three different variables were collected in concentric phase, peak torque, peak torque to body weight, and the total work to body weight using Bidex System 4. **Results & Conclusion:** The majority of quadriceps strength parameters relate to peak force during 10 jumps test. Hamstring strength would appear to relate to peak force, peak velocity, time to peak force, and time to peak power during 10 jumps test. Strength in both quadriceps and hamstring does not appear to correlate to any force parameters during isometric mid-thigh pull test for either injured and non-injured limbs.

Sociology

CHANGING DISCRIPTIONS OF THE CONCEPT OF SPORT FOR PEOPLE WITH DISABILITIES: A COMPARISON BEFORE AND AFTER A DISABILITY-INCLUSIVE SPORT CLASS

MORIKAWA, H., KANEKO, M.

Teikyo Heisei University, Toyo University

Introduction In the fields of education, sport and social work in Japan, the concept of sport has often been discussed. Over the past several years, although many researchers have shown an interest in disability sport, little studies have been conducted to explore the viewpoint of sport for people with disabilities. Therefore, the aim of this study is to examine the change descriptions of sports for people with disabilities. **Methods** The subjects of this study were ninety university students who participate in disability-inclusive sports. The purpose of this investigation is to ascertain factors of sports for people with disabilities (physical, intellectual and mental). Questionnaire were prepared to investigate this, and were administered to students at the start and end of each disability-inclusive sports class. Their sentence data were analyzed by using language analysis software (KH Coder). The whole picture and relationships among the factors were visualized using a co-occurrence network and correspondence analysis. **Results** The results showed that attitudes changed about which sports the students believed were suitable for people with disabilities (physical, intellectual and mental). **Discussion** At the start of the classes, the language used for talking about sports for people with intellectual disabilities were similar to those for people with mental disabilities. However at the end of the classes, it appeared that there were differences in the language used to talk about sport for people with intellectual disabilities and people with mental disabilities. The words used when referring to sport for intellectual disabilities changed from "health" and "difficult" to "power," "grow," and "change"; and those for mental disabilities from "mood" and "difficult" to "rehabilitation," "affirmation," and "positive". Furthermore, those for people with physical disabilities changed from "physical," "enjoyment," and "recreation" to "life" and "win." Considering these matters, before the classes there was a description concerning extrinsic value, and after the classes concerning intrinsic value. It is necessary to consider integrating their shift in response toward the intrinsic value of a disability sport curriculum. Japanese researchers have tended to distinguish the concept of sport between "lifelong sport." To evolve, the sports for people with disabilities must place emphasis on intrinsic value of sport. A further study of how people with disabilities replied to the questionnaire should be conducted. It is hoped that the outcome of the present study would be of some use to develop a curriculum of sport trainers for disabled people.

INVESTIGATION OF JAPANESE GIRLS' NONPARTICIPATION IN SPORTS AND PHYSICAL ACTIVITY

SATO, K., TANAKA, H.I

1:BIWAKO SEIKEI SPORT COLLEGE (Japan)

Introduction Recently, Japanese female athletes have begun to actively participate in national level sports. For instance, the female soccer team won their first gold medal in the 2011 FIFA Women's World Cup, and the female volleyball team won a bronze medal in the London Olympics for the first time in three decades. However, female sports in Japan are currently encountering various problems, a major one being that many girls give up sports and physical activity citing a long list of reasons such as relationships, dieting, intense training, etc. (Yumiko, 2012; Michio, & Kazuyoshi, 2012; Mayumi, 2001). The objective of this study was to examine nonparticipation rates, involvement, and interest in female sports and physical activity. **Methods** The study's research was based on a focus group of adolescent girls, aged 13–17 years (n=477), and investigated their perspective of sports and physical activity (e.g., interest, involvement, and frequency) and self-efficacy. Boys were also included in the study as was convenient for the analysis, though the girls were the main focus. The data were statistically analyzed using SPSS version 19 for the students' t-test and Chi-square test. **Results** 1) A number of girls give up sports and

physical activity (excluding physical education) when transferring to high school (from 14 to 15 years old). 2) Girls do not participate in sports and physical activity because they dislike it. 3) Many girls have never performed sports and physical activity because they did not like it. 4) Self-efficacy had a significant relationship with nonparticipation and participation (e.g., items such as confidence and positive attitude). Participation was significantly higher than nonparticipation (e.g., confidence, $t=4.47$, $P<.01$). 5) Boys' participation in sports and physical activity was significantly higher than that of girls, and a number of boys were trying to continue participation after transferring to high school ($\chi^2=23.9$, $P<.000$). Conclusion We found that many girls gave up sports and physical activity or had never done either, the most common reason being that girls did not like them. It is important that girls gain some experience in sports and physical activity, some interest, and parental advisement in childhood. On the other hand, many boys have experience in at least one sport or physical activity, and girls' experience was significantly lower than that of boys. Reference Mayumi, N. (2001). THE IMPLEMENTATION OF THE ADVANCED APPRENTICESHIP IN SPORTING EXCELLENCE IN THE UK

LEE, P., LIN, C., HUANG, H.

National Taichung University of Education, National Chung Hsing University, National Cheng Kung University

Introduction It is increasingly recognized that helping talented student-athletes to cope with their educational/career development and sporting performance is one of the most commonly encountered issues in different countries. In the UK, the Advanced Apprenticeship in Sporting Excellence (AASE) which is a sports performance program established in 2004, is a government backed partnership between talented young athletes (aged 16-19), families, coaches, educational institutes, NGBs. It is recognized as an exemplar model of families' support which contributes to student-athlete training and competing support to develop and reach their maximum potential, whilst at the same time continuing their education/career development. **Objectives** This discussion is about elite sport and primarily about how the UK provides lifestyle support for the talented young athletes with a concern of major contributions of implementing the AASE. **Materials & Methods** The empirical research was conducted between November 20th to 29th, 2014 and November 5th to 17th, 2015. It consisted of eight in-depth interviews including AASE administrators, college teachers, parents, coaches, athletes. The interview data are supplemented by analyses of British government policy documents, academic articles, media publications etc. **Results & Discussion** In 2004, the SkillsActive, NGBs and industry experts administered an AASE program which serves talented young athletes as an initiative to receive the support and training for pursuing the success in elite sport. Athletes can complete the AASE through one of two pathways (Pathway one, Pathway two) and four requirements (Functional skills, Personal learning and thinking skills, Employee rights and responsibilities, Exemption from the mandatory employment). The major services/units were provided through the AASE program, namely, technical skills, tactical skills, physical capability, nutrition psychological skills, lifestyle management, career planning, health and safety, communicating as an athlete (SkillsActive, 2016). In our study, it shows that AASE administrators, college teachers, parents, coaches, and athletes acknowledged the implementing AASE aids athletes to achieve excellence in their sport as well as to prepare academic/career development. **Conclusions** The AASE introduced in 2004 has been formalized and extended. To some extent, delivery of the AASE has met those 'needs' of government, NGBs, schools, families, coaches and talented young athletes in some elements. From the relevant stakeholders' perspectives, this implies that such a scheme is able to assist talented young athletes balance other aspects of their sport training and competing with counting education/career development. And, the major contributions/implications of the AASE are concluded as the followings: well-quipped facilities, parent's support, quality coaching, and athlete education/career development. **References** SkillsActive. (2016). AASE. Retrieved from: <http://www.skillsactive.com/standards-quals/apprenticeships/aase>

Sport Statistics and Analyses

SURVEY ON AWARENESS ABOUT SPORTS AND IMPLEMENTATION STATUS OF SPORTS ACTIVITY AMONG VISUALLY IMPAIRED PEOPLE IN JAPAN

KONDO, H.1, KINOSHITA, H.1, KOHDA, Y.1, MIYAKAWA, S.2, MIYAMOTO, T.2

1: National University Corporation of Tsukuba University of Technology/Tsukuba, Japan, 2: University of Tsukuba/Tsukuba, Japan

Introduction Continuation of sports and exercise is paramount in maintaining and improving the health of individuals with visual impairments, and also in maintaining their quality of life. The purpose of this study is to prepare basic data for ascertaining the attitudes of individuals with visual impairments toward sports activities, and understanding the extent to which such individuals are carrying out these activities. **Methods** The Participants in this study were 515 individuals (40.1 ± 13.8 ages) who have visual impairments. We conducted an anonymous questionnaire survey. We delegated the implementation of the survey to an online survey company. We recruited the participants from a list of monitors owned by the online survey company. The survey items included Participants of the attribute, awareness of sports activities, implementation status of sports activities. Results 53.2% of the participants had a severe visual impairment. Of the total participants, 78.0% answered that sports activity is essential, or essential to some extent. 30.1%, the highest proportion, answered that they participated in sports/exercise once or twice a week. The type of activity with the largest proportion of responses was walking at 65.8%. Most of the participants (71.6%) cited "to build health/physical strength" as the reason for participating in sports or exercise. As for the reasons for not participating in sports or exercise, "because of eyesight issues" had the largest proportion of responses at 35.9%. Most of the participants (57.0%) answered that they rely on their family or relatives for getting to the venue. **Discussion** Previous studies have investigated the sport implementation rate of adult and disabled people. This result suggests that the rate of sports engagement among individuals with visual impairments is lower than that of the general adult population, but higher than that of adults with a disability. The reason for participating in sports or exercise that was most frequently cited by the individuals with visual impairment was "to build health/physical strength." This finding suggests that those with or without disabilities alike share an interest in health, and that people with visual impairments engage in relatively simple sports like walking and calisthenics to a similarly frequent extent as those in the general adult population. As for the reasons for not participating in sports or exercise, "eyesight issues" was the most frequently

cited reason. Other than "eyesight issues," the reasons for not participating in exercise were the same as the top reasons in the results of the survey conducted on adults. This finding suggests that when it comes to sports and exercise, the visual impairment factor is both particular to individuals with visual impairments and is also the greatest factor inhibiting them from engaging in sports and exercise.

DIFFERENCES IN DIETING METHODS BETWEEN GENDERS AND JAPANESE AND ASIAN OVERSEAS STUDENTS

AOYAGI, O.1, SAKAGUCHI, H.2, ANNOURA, T.2, CHOI, T.3, HAN, N.3, HONG, T.3, NAM, Y.4, KOO, K.5

1: FU (Japan), 2: NKU (Japan), 3: JNU (Korea), 4: DWU (Korea), 5: CNU (Korea)

Introduction These days, many young people are overly obsessed with being slim. This had caused the issue of excessive or inappropriate dieting behaviors. How an individual diets depends on their gender and nationality, which also affects cultural norms and thoughts related to the body and health. This study aimed to investigate the differences in dieting methods between young men and women and between Japanese and Asian overseas students. Methods Based on Matsumoto et al. (1997), a questionnaire survey consisting of 22 items about dieting methods was conducted with 1003 Japanese and Asian overseas students at N-university in January 2015. The 463 students (162 Japanese and 301 Asian overseas students; 293 males and 170 females) who indicated that they had previous dieting experience were included in the analyses. Students were asked to choose one response out of the following four options: "I am doing it now (now)," "I did it in the past (past)," "I have never done it but I am interested in it (interest)" and "I am not interested in it (never)." After the responses were categorized into Japanese males, Japanese females, Asian overseas male students and Asian overseas female students, cross tables were created. The tendency was investigated using significantly greater adjusted residuals in the cross table. Results Significant differences were found in all items except for two items. Japanese males had the greatest number of significant adjusted residuals with 15 responding "never" among four options, Japanese females with seven responding "past," Asian overseas males with seven responding "Interest," and Asian overseas females with 11 responding "now." If we assume that interest in dieting decreases in descending order of "now," "past," "interest," and "never," it can be said that Asian overseas females had the highest interest in dieting, followed by Japanese females, Asian overseas males, and Japanese males. Greater differences in the interest in dieting method were detected in gender than nationality in seven items, such as "I do not eat sweets or high calorie foods", indicating female predominance. More noticeable differences based on nationality were discovered in three items, such as "I take laxatives in order to lose weight", than those based on gender. Gender difference not found in oversea students but found in Japanese students was detected in three items, such as "I do not eat the recommended foods and drinks because I have become fat." In contrast, gender differences among Asian overseas students were observed in two items including "I restrict my calorie intake", indicating that females had higher interest in dieting method. RELATIONSHIP BETWEEN KNEE ANGLE IN SQUAT TEST AND DEFENCE OR RECEPTION EFFICACY IN AMATEUR VOLLEY-BALL PLAYERS

MUNERATI, P., ROSSI, A., CAVAGGIONI, L., FORMENTI, D., ALBERTI, G.

Università degli Studi di Milano (Milano, Italy)

Introduction Defending and receiving successfully in volleyball is necessary to produce good attacks. The most used technique of defence and reception is dig. It was found that performance of dig influences the performance of spike (Palao et al., 2006). Key points for the effectiveness of dig are anticipation, decision-making, and movement speed. However, it is legit to hypothesize that knee joint angle (KJA) in the starting position of the dig may have an influence on defence and reception efficacy. Therefore, we aimed to investigate the relationship between KJA during an overhead squat test and both defence efficacy (DE) and reception efficacy (RE) in amateur volleyball players. Methods Fifteen amateur volleyball players were recruited (20.27 ± 3.08 yrs, 76.60 ± 9.27 kg, 184.53 ± 6.63 cm). Players performed three trials of the NASM overhead squat test (Clark 2001) aimed to detect the minimum knee angle value just before losing inverting the normal lumbar lordosis. The KJA was assessed using Microsoft Kinect™. After that, DE of each player was assessed in response to 15 test spikes performed by the same player, as well as RE was assessed in response to 15 test services performed by the same player (Palao et al., 2015). After checked for the normality of the distributions, Pearson correlation coefficient was calculated between KJA and both DE and RE. A p-value lower than 0.05 was considered statistically significant. Data are presented as means \pm SD. Results The KJA in the squat test was 103.9 ± 13.4 deg; DE was -41.3 ± 22.9 % and RE was 46.6 ± 20.9 %. Correlations between KJA and DE and KJA and RE were -0.7 ($p=0.004$) and -0.14 ($P>0.05$), respectively. Discussion The significant inverse correlation between KJA and DE suggests that the players with knee angle lower just before losing the normal physiological lumbar curve had a better efficiency during the defence position. From a speculative point of view, the major depth reached the quality of movement in the squat test reflects a better technical performance the quality of movement in the defensive stance; generally, the squatting depth positively influences the lower-body jumping and postactivation potentiation (Esformes & Bampouras 2013). Conversely, the non-significant correlation of KJA and RE was probably due to the more time from the service to the dig, allowing the receivers more time to prepare the reception. SCALING OF DEFENSIVE TACTICAL PERFORMANCE FROM TRACKING DATA OF SOCCER GAME

MATSUOKA, H., MISHIO, S., NAOMOTO, H., KUMAGAI, S., ANDO, K., NISHIJIMA, T.

UNIVERSITY OF TSUKUBA

Introduction Game analysis using tracking data in soccer has become popular in the world. However, soccer defensive tactical performance (SDTP) measurements has not analysed sufficiently. The purpose of this study was to construct SDTP variables by using tracking data of a soccer game. Methods An official game of J-league in 2015 season in Japan was analysed to measure SDTP. The SDTP variables with content validity were consisted from pressing defence (PDF), retreat defence (RDF) and shoot defence (SDF), using the causal-effect analysis and Delphi method with five experts qualitatively. The SDTP variables were measured from x-y coordinates of all field players during ball lost through ball gain or opponents shoot extracted from the tracking data. Total number of SDTP was 102 plays in a game (44 in PDF, 37 in RDF, and 21 in SDF). PDF and RDF were defined as successful defence, and SDF was defined as unsuccessful. SDTP variables were analyzed using descriptive statistics. Binomial logistic regression analysis was used to analyse the effective correlation of SDTP variables to defensive performance (successful or unsuccessful). The statistical significant level $P < .05$ was set. SPSS 22 (SPSS Inc., Chicago, USA) was used for analysis. Results Distance between ball and the 1st and the 2nd defenders (DFs) at the beginning of defen-

sive play, distance covered by from FW player, distance covered by bottom DF player from the beginning to the end of defensive play, velocity and position of final DF line which distance from own goal line from the beginning to the end of defensive play, area of front five players and area of back 5 players at the end of defensive play were investigated as SDTP variables by Delphi method. Distance between ball and the 1st defender (odds ratio (OR) = 1.502, p= .41), and the 2nd DF (OR = .672, p= .49) at start of defence, distance covered by FW player (OR = .844, p= .48), distance covered by DF player (OR = 1.428, p= .007), and position of final DF line (OR = 1.600, p= .004) were correlated with the defensive performance, respectively. Discussion The distance between ball and the 1st and the 2nd DFs at the start of defensive play is a key factor of defensive tactical play. Available of the 1st DF to reduce the opponent attacking speed is one of key component of defensive tactical skill of soccer (Suzuki & Nishijima, 2007). The distance covered by FW and DF, and position of final DF line directly relate with control of opponent attack such as decreasing opponent attacking space. In conclusion, these SDTP variables are statistically valid to use for defensive performance analysis in soccer games. Reference Suzuki, K., & Nishijima, T. (2007). Sensitivity of the soccer defending skill scale: a comparison between teams. European Journal of Sport Science, 7(1), 35-45.

DEVELOPMENT OF A NEW METHOD USING SEQUENCE ANALYSIS FOR CLARIFICATION OF THE ATTACKING TACTICS IN HANDBALL

ICHIMURA, S.1, MORIGUCHI, T.2, SHIMIZU, N.3, FUKUDA, J.4, MIYAZAKI, S.1

1:Tokyo University of Science, 2:Fukuoka University, 3:International Budo University, 4:Miyazaki University

Introduction Notational analysis quantifies for tactical actions as "When", "Where", "Who", "What" and "How" and can be used for evaluation of game performance. In general, a notational analysis can assess the total tactical behavior and the important aspects of the game to evaluate single actions. In order to gain deeper insight into the tactical behavior of the individual and team, it is necessary to record the multiple tactical actions and to analyze the sequence of continuous attacking actions in time-series. Thus, we considered a new method to analyze the multiple tactical actions using sequence analysis in the ball game, like a sequence analysis of nucleotide of DNA. Methods We analyzed the offense set-plays of 42 games in 2012 European Women's Handball Championship in Serbia. In total, 21381 single attacking actions were recorded. The single attacking action were classified according to a definition and encoded for these attacking actions. The classification definitions of attacking action were (1) the direction of passing the ball and attacking action of player 1, (2) The timing which starting a movement of player 2, and (3) The attacking direction of the player 2 against the passed direction from player 1. The classified attacking actions were arrayed from opening to terminating play in time-series. The one attacking sequence was defined as the continuous attacking actions from opening to terminating play. The definition of terminating attacking action was "shooting", "technically miss", "technical fault" and "foul by defender". In this study, we examined the useful combination of attacking actions in opening phase, terminating phase and continuous phase. Results We could classify the 15 kinds of single attacking actions according to the classification definition. These classified attacking actions were encoded to a letter of alphabet as T, W, X, Y, H, P, D, F, R, I, Q, E, G, S and C. The numbers of attacking sequence were 1983. In comparing among attacking phase, the kinds of four combinations attacking action were 190 in opening phase, in 312 in terminating phase, 300 in continuous phases, respectively. In opening phase, "T-T-W-T", "T-T-F-T", "T-T-F-W", "T-W-T-R", "T-W-T-W" and "T-W-P-R" of four combinations of attacking actions were more used compared to other phases. In terminating phase, "F-T-H-D", "H-P-P-F", "H-T-H-D", "T-F-P-F", "T-F-R-F", "T-H-T-P" and "W-T-H-D" of those were higher observed than other phases. In continuing phase, "F-R-R-T", "F-T-H-T", "H-T-H-T", "H-T-T-W", "P-R-T-H", "R-P-H-T", "R-P-R-T", "T-H-T-T", "W-P-H-T", "W-P-R-W", "W-T-F-W", "W-T-H-T", "W-T-R-T", "W-T-R-W", "W-T-T-T", "W-T-W-T", "W-T-W-W", "W-W-T-W" and "W-W-W-T" of those were well observed. Theses results demonstrated that the more useful combination attacking actions differed among the attacking phase. Conclusion We found the difference of attacking tactics among attacking phases. This result indicated a potential of our new analysis methods using sequence analysis. Contact shiro@rs.noda.tus.ac.jp

Sport Technology

ANALYSIS OF ANTICIPATION BY INTEGRATION OF EYE TRACKING IN VIRTUAL REALITY – AN INNOVATIVE APPROACH

WITTE, K.1, SALB, S.1, PETRI, K.1, BANDOW, N.1, EMMERMACHER, P.1, ZHANG, L.2, BRUNNETT, G.2, MASIK, S.3

1: OvGU (Magdeburg, Germany) 2: TUC (Chemnitz, Germany) 3: Fraunhofer IFF VDTC (Magdeburg, Germany)

Introduction It is commonplace to analyze anticipation in sports by usage of eye tracking and occlusion techniques to study foveal and peripheral perception in combination for anticipatory cue detection. Most studies exploring anticipation in sports used video screens for stimulus presentation. A virtual environment provides conditions close to reality due to depth information and standardized conditions. An additional advantage is that for training or investigations in virtual reality (VR) there is no dependence on other athletes. However, eye tracking, occlusion techniques and VR have never been combined. The aim of this project is to describe preparatory work in the field of eye tracking in 2D and in the field of occlusion techniques in VR and to give an outlook to combine all three technologies. Methods Reactions of expert karate athletes (n=5) were analyzed via high-speed video (200Hz) while responding to occluded attacks shown on a life-size video screen and in a virtual environment. Furthermore visual search behavior of karate experts (n=7) was investigated using a head-mounted eye tracker (SMI ETG1) while responding physically to occluded attacks shown on a life-size video screen. Results Statistical data analysis revealed a significantly ($p<.05$) higher number of correct responses in the virtual environment compared to 2D video presentation. Also first anticipatory cues could be determined. Analyzing the data of the eye tracking experiment the opponent's head and upper torso were found to be main fixation regions (e.g. 58% head and 22% upper torso under non occluded condition). Discussion and Recommendation Better reactions in VR are caused by depth information which evokes a more realistic feeling in the environment and higher immersion than 2D video presentation. In future approaches eye tracking and occlusion techniques shall be implemented in virtual reality to gain the advantages from all technologies. Wearing a head mounted eye tracker in a CAVE (Cave Automatic Virtual Environment), eye movements can be detected in VR but spatial limitations inhibit sport specific applications. Hence the integration of an eye tracker in a head mounted display (SMI Oculus Rift Integration) appears to be the most suitable solution. This provides immersive stimulus presentation with high mobility enhancing natural movements. To allow natural interaction between an avatar and a real athlete in VR it would desirable to develop an autonomously interacting environment for studying anticipation in sports. Sports Medicine and Orthopedics

THE EFFECT OF ACUTE EXERCISE MODALITY ON INTRADIALYTIC BLOOD PRESSURE IN HEMODIALYSIS PATIENTS

KIM, Y.1, KIM, J.1, YI, J.2, SHIN, J.2, HAN, S.2, KANG, H.3, CHOI, H.4

1Seoul National University, 2Hanyang University Hospital, 3Soonchunhyang University, 4Ansan University, KOREA, REPUBLIC OF,

INTRODUCTION AND AIMS: Blood pressure (BP) in hemodialysis patients is a modifiable risk factor for long-term mortality and its alteration during dialysis such as symptomatic intradialytic hypotension is a poor prognostic marker. Exercise has been known to have influences on BP in these patients. The purpose of this study is to investigate the effect of acute aerobic, resistance exercise on the BP during dialysis. **METHODS:** During hemodialysis, 11 patients were performed 2 sets of aerobic or resistance exercise with 1 hour rest in between sets. All patients were conducted aerobic, resistance exercise and no exercise for three consecutive weeks. Each intervention was separated by at least 7 days, to avoid a training effect. BP was measured during 4 hours of dialysis every 10 to 30 minutes. Paired t-tests or a repeated measure ANOVA and post hoc test were used to compare each time point within or among three exercise modalities, respectively. **RESULTS:** Two exercise programs were well tolerated, with no complications during the study. In both aerobic and resistance exercise systolic BP increased during exercise and fell after exercise except for during 1st set of aerobic exercise. In each time period, only resistance exercise significantly increased systolic BP compared with untreated among three individual modalities ($P < .05$). The patterns of diastolic BP were similar with those of systolic BP during intradialytic period. **CONCLUSIONS:** During dialysis period, both acute aerobic and resistance exercise increased BP during exercise and decreased BP after exercise in hemodialysis patients. Both aerobic and resistance exercise deserve future investigations on the effects of acute intradialytic exercise on BP and symptoms when applied in intradialytic hypotensive patients.

GENDER RELATED DIFFERENCES OF ACHILLES TENDON CROSS-SECTIONAL AREA AT REST AND MAXIMAL VOLUNTARY CONTRACTION AMONG CHILDREN

RAUF, S., INTZIEGANINI, K., CASSEL, M., WHITE, S., SHAFQAT, A., MAYER, F.

University of Potsdam

Introduction: Larger Achilles tendon cross-sectional area (AT-CSA) yields a reduced average tendon stress for a given force (Westh et al., 2008). At a given force a compliant tendon CSA reduces more from rest to contraction (Muraoka et al., 2005). Females tend to have smaller CSA and more compliant AT than males (Maganaris et al., 2008). This difference is more obvious in adults however in children this phenomenon is not clear. **Purpose:** To investigate gender related differences of AT-CSA at rest and maximal voluntary contraction (MVC) among children. **Methods:** Left AT-CSA of 14 healthy adolescent athletes (7 boys, 7 girls; 13 ± 2 yrs; 158 ± 12 cm; 49 ± 16 kg) was sonographically assessed during rest and MVC under 5s. Subjects were positioned prone on an isokinetic dynamometer with knee extended and ankle placed at 90° in a footplate. AT-CSA (4 cm from distal attachment on the calcaneus) was measured using a custom-made cast over 3 trials and the average was taken. Data was analyzed descriptively (mean \pm SD) for each group. Differences between groups were analyzed using independent t-test ($\alpha = 0.05$). **Results:** Mean AT-CSA for boys was 55 ± 10 mm² at rest and 50 ± 9 mm² during MVC, for girls the values were 44 ± 11 mm² at rest and 39 ± 7 mm² during MVC. Mean CSA difference between rest and MVC was -4 ± 4 mm² for boys and -5 ± 4 mm² for girls. AT-CSA was found to be statistical significant larger in boys at rest ($p = 0.007$) and at MVC ($p = 0.003$) compared to girls. Muscle torque during MVC for boys reached 65 ± 23 Nm and for girls 60 ± 24 Nm. No statistical significant differences were found for AT-CSA from rest to MVC ($p = 0.713$) as well as for muscle torque ($p = 0.701$) between the groups. **Conclusion:** The larger CSA in boys compared to girls during rest and MVC is already visible at an average age of 13 years. AT-CSA reduction from rest to MVC showed no gender-related differences; implying no differences in tendon compliance at these ages. Further research including other methodological approaches and higher sample sizes are necessary to understand the properties of AT among children. **References:** Westh, E., Kongsgaard, M., Bojsen-Møller, J., Aagaard, P., Hansen, M., Kjaer, M., & Magnusson, S. EPIDEMIOLOGY OF FEMALE COLLEGIATE FOOTBALL TEAM INJURIES FOR TWO YEARS

ODA, K.1,2, OGAKI, R.2, MURAKAMI, K.1, YAMAGUCHI, T.1, TAJAHASHI, Y.1, KUROSAWA, T.1, MIYAKAWA, S.2

1Sendai University 2University of Tsukuba

Introduction: Football is played worldwide by more than 265 million players, of whom 26 million are female players (Astrid et al., 2007). The popularity of female football players in Japan has been rising since the winning of FIFA World Cup championship in 2011. The number of population continues to increase every year and exceeds approximately 30,000 today. Football requires physical contact, and therefore associates with a large number of injuries in both sexes. Injuries in male football have been the subject in many studies. However, the number of reports regarding female football injuries in adults is low and epidemiologic date in Japanese collegiate female football players is very rare. The aim of this study was investigating the injuries in Japanese female collegiate football players in two seasons (2014-2015) using definitions established by the Federation International de Football Association (FIFA). **Methods:** A total of 32 female collegiate football players (mean height = 159.3 ± 7.1 cm, mean weight = 57.0 ± 7.3 kg) participated in the study. We investigated the injured situation (game or practice, contact or non-contact), type of injury (traumatic or overuse), location, severity, days until return to play, and a month that the injury occurs. Injuries were classified into the following three categories according to FIFA severity. **Results:** Overall, 76 injuries were documented in 25 players (78.1%). 82.9% of injuries were traumatic and 17.1% were overuse injuries. 31.6% of injuries were occurred during games and 68.4% were during practices. 36.2% of injuries were caused by the contact play and 65.8% were non-contact play. Most injuries (85.5%) were located in the lower extremities with affecting thigh (32.9%), ankle (23.4%), and knee (17.1%). The days taken until return to play with injuries during game and practice were 46.9 ± 69.4 and 17.1 ± 19.8 respectively. April was the predominant month for injuries (25.0%). **Discussion:** As with other studies, our results show that the most injuries occurred in lower extremity. However, the days taken until return to play was longer in our study than its other studies (K. Söderman et al 2001). The results suggest that, in addition to the rehabilitation that focuses on early recovery, reducing severity of injuries by applying the preventive intervention of lower extremity injuries is the crucial strategy to shorten the return to play in female football players. **References:** 1.Junge A, Dvorak J.

MRI FEATURES OF THE TRUNK MUSCLES IN MALE COLLEGIATE SPRINTERS WITH LUMBAR DISK DEGENERATION

TAHARA, Y., NAKAZATO, K., KOYAMA, K., ISHII, T., MIZUNO, M., BEPPU, K., HIRANUMA, K.

Nippon Science Sport University, Tokyo Ariake University of Medical and Health Sciences

Introduction Lumbar disk degeneration (LDD) is a common cause of low back pain (LBP) in athletes. Previous studies have reported higher prevalence rates of LDD among athletes (Hangai et al., 2009). However, despite the high prevalence among athletes, the predictive factors of LDD have not been fully clarified. Many studies have reported a direct correlation between LBP and cross-sectional areas (CSAs) of the trunk muscles in the general population. We hypothesized a significant relationship between LDD and CSAs of the trunk muscles in athletes. The purpose of this study was to investigate the association between LDD and the CSAs of the trunk muscles in Japanese male collegiate sprinters. Methods The subjects were 48 Japanese male collegiate sprinters. LDD and CSAs were evaluated by using T1- and T2-weighted magnetic resonance imaging (MRI). LDD was defined as reduced signal intensity of the intervertebral disks from L1/L2 through L5/S1. The grading system for the assessment of LDD was based on the Pfirrmann classification, with grades 3–5 indicating degeneration (Pfirrmann et al., 2001). According to this evaluation, we assigned the sprinters into 2 groups, namely the LDD group ($n = 8$) and non-LDD group ($n = 40$). The CSAs of the trunk muscles at the L3/L4 and L4/L5 disk levels were measured on MRI. We calculated the CSAs of the following muscles: rectus abdominis, obliquus, psoas, quadratus lumborum, and erector spinae. All the CSAs were normalized by the CSAs of the corresponding intervertebral disk. Results The LDD group had larger CSAs of the trunk muscles than the non-LDD group (obliquus: $p < 0.01$; psoas: $p < 0.05$) at level L4/L5 of the intervertebral disk. Furthermore, the CSAs were significantly asymmetrical between the left and right sides at the L4/L5 disk level in the LDD group (obliquus: $p < 0.05$). Discussion In this study, we found that the LDD group had a significantly larger CSAs of the trunk muscles (both the oblique and psoas) than the non-LDD group. Arbanas et al. reported that patients with LBP had larger CSAs of the psoas major muscles. The CSAs of the trunk muscles (size and asymmetry) might affect not only LBP but also LDD. In conclusion, the CSAs of the trunk muscles is a predictor of LDD in Japanese male collegiate sprinters. DIFFERENCES IN QUADRICEPS MUSCLE THICKNESS IN JAPANESE JUNIOR HIGH SCHOOL AND COLLEGE BASKETBALL PLAYERS

SEKINE, Y., HOSHIKAWA, S., OKADA, J.

Nippon Sport Science University

Introduction Quadriceps muscle thickness (MT) is associated with sprint and jump performance. Prior studies have reported that bilateral differences in muscle architecture are related to lower extremity injuries. However, the difference in quadriceps MT among different age groups of athletes is unclear. This study investigates differences in quadriceps MT between elite Japanese junior high school and college basketball players. Methods Nineteen male junior high school (JHS; age 13.8 ± 0.7 yrs, height 168.0 ± 11.8 cm, body mass 56.5 ± 13.4 kg, history of competition 5.2 ± 1.7 yrs) and college basketball players (CS; age 19.7 ± 1.1 yrs, height 190.9 ± 4.5 cm, body mass 86.0 ± 7.9 kg, history of competition 9.4 ± 1.8 yrs) volunteered for this study. Quadriceps MT of the vastus medialis obliquus (VMO), vastus medialis (VM), rectus femoris (RF), vastus intermedius (VI), and vastus lateralis (VL) was measured using real-time ultrasonography (Giles et al., 2015). Images were analyzed by software after being classified as dominant leg (DL) or non-dominant leg (NDL). The ratio of MT to body mass $^{1/3}$ (MT/BM $^{1/3}$ ratio) was calculated to normalize morphological differences. Independent t-tests were used to compare MT and MT/BM $^{1/3}$ ratio between JHS and CS. To evaluate differences in MT between DL and NDL of each player within an age group, paired sample t-tests were performed. The significance level was set at 0.05. Results CS had greater MT of DLVM ($p=0.006$), NDLVM ($p=0.001$), DLRF ($p=0.017$), NDLRF ($p=0.006$), DLVI ($p=0.031$), and NDLVL ($p=0.023$) compared with JHS. For the MT/BM $^{1/3}$ ratio, NDLVMO in JHS was significantly greater than in CS ($p=0.038$). The MT of VMO and VI in DL was significantly greater than the MT in NDL for CS (VMO: $p=0.014$, VI: $p=0.047$). Discussion Muscle growth velocity corresponds with peak mass velocity between 7-17 years of age (Malina et al., 2004). Quadriceps muscles in CS are thicker than in JHS, except for VMO; this difference between the groups is the effect of aging on muscle growth. However, the MT/BM $^{1/3}$ ratio of VMO was recognized less than JHS and laterality of quadriceps MT was found in CS. History of competition and injury may affect the laterality of quadriceps MT in CS. Muscle imbalance is a risk factor for lower extremity injury (Mangine et al., 2014). The results of this study indicate the importance of improving the laterality of quadriceps muscle thickness in CS. References Giles LS, Webster KE, McClelland JA, Cook J. (2015). CARDIORESPIRATORY FITNESS AND NEUROCOGNITIVE PERFORMANCE IN THE ELDERLY WITH MILD COGNITIVE IMPAIRMENT

TSAI, C.L.1, PAI, M.C.2, UKROPEC, J.3, UKROPCOVÁ, B.3, PAN, C.Y.4

1: NCKU (Tainan, Taiwan), 2: NCKUH (Tainan, Taiwan), 3: SAS (Bratislava, Slovakia), 4: NKNU (Kaohsiung, Taiwan)

Introduction Thus far, no studies have yet been conducted that explore the potential correlation between cardiorespiratory fitness and neurocognitive (i.e., neuropsychological and neurophysiological) performance in elderly individuals with mild cognitive impairment (MCI). Therefore, the aim of this study was to investigate the role of cardiorespiratory fitness in the relationship between neurocognitive performance and MCI. Methods Fifty-six participants were classified into MCI ($n=28$) and control ($n=28$) groups, and were monitored with regard to their behavioral performance (e.g., accuracy rates and reaction times) and event-related potential measures (e.g., P3 latency and amplitude) during a variant of the task-switching paradigm, and also underwent a cardiorespiratory fitness test. All independent variables were separately analyzed with a repeated-measures ANOVA. Results Although no significant difference was observed in accuracy rates between the two groups, the MCI group showed slower reaction times in the heterogeneous condition and larger global switching costs when performing the task-switching paradigm. Additionally, the MCI group exhibited significantly longer P3 latencies in the homogeneous and heterogeneous conditions, and a smaller P3 amplitude only in the heterogeneous condition. The MCI group relative to the control group showed poorer VO_{2max} values. The level of cardiorespiratory fitness was significantly associated with P3

amplitude, particularly in the heterogeneous condition of the task-switching paradigm, in the MCI group. Discussion The MCI group showed abnormalities in neurocognitive performance when performing the cognitive task, and this extends the body of research exploring the neuropsychological performance of people with MCI (Belleville et al., 2008). Such a deficit (e.g., P3 amplitude) was likely correlated with poorer cardiorespiratory fitness. A physical exercise intervention leading to improved cardiorespiratory fitness may thus have non-pharmacological protective effects on the functional integrity of the MCI patients' brains and cognition (Colcombe and Kramer, 2003). However, the cross-sectional research design does not allow us to address the issue of directionality or causation, and such a correlative approach cannot sufficiently explain the potential mediating effects of cardiorespiratory fitness on the neurophysiological problem. ALIGNMENT OF TRUNK AND LOWER LIMBS DURING STAR EXCURSION BALANCE TEST MIGHT BE USEFUL TO CATEGORIZE ACL INJURY RISK

UEBAYASHI, K., AKASAKA, K., TAMURA, A., OTSUDO, T., SAWADA, Y., OKUBO, Y.

Sekishindo Hospital.

【Introduction】 Some reports have indicated that categorization of ACL risk during sports movement among athletes is important to reduce ACL injuries. ACL injuries are occurred during sports, especially jump landing and cutting movements with knee valgus alignment. Because ACL injuries were occurred during movements toward to various directions, we considered that alignment of trunk and lower limb during Star Excursion Balance Test (SEBT) might be useful to categorize ACL risk of supporting leg. Therefore, the purpose of this study was to clarify the relationship of knee valgus alignment during single leg drop landing (SDL) and alignment of trunk and lower limb during SEBT. 【Methods】 28 healthy females (age = 20.6±1.2 years old, height = 159.3±4.7 cm, weight = 51.3±4.3 kg) volunteered to participate in this study. All of them gave written informed consent before this study. The 3D motion analysis system was used to measure trunk, hip and knee angles during SDL and SEBT. All participants were divided into the knee valgus group (more than 5 degrees in knee valgus displacement) and the control group (less than 5 degrees in knee valgus displacement) during SDL. Trunk, hip and knee angles of right leg (supporting leg) were analyzed from the starting position to the maximum reach during SEBT. Independent t-test was used to identify differences of trunk, hip and knee angles during SEBT between two groups. 【Results】 The knee valgus angles in knee valgus group were greater than those in control group during reach direction of anterior (A), anterior medial (AM), anterior lateral (AL), medial (M), and posterior medial (PM; p<0.05), respectively. In addition, the hip internal rotation angle in knee valgus group was less than those in control group during reach direction of AM and AL (p<0.05). Furthermore, the knee flexion angle in knee valgus group was less than that in control group during reach direction of M (p<0.05). The trunk right rotation in valgus group was also less than that in control group during reach direction of PM (p<0.05). 【Conclusion】 In addition to an increase of knee valgus, increase of hip internal rotation, decrease of knee flexion and trunk rotation to supporting leg were reported as a risk factor of non contact ACL injury during landing and cutting movements. It was considered that decrease of hip internal rotation might be one of ACL injury risk found as a characteristic influenced by the SEBT. Our results indicate that reach direction of A, AM, AL, M and PM during SEBT would be useful to detect ACL injury risk.

HEAT STIMULATION-INDUCED INCREASE IN HSP70 EXPRESSION ENHANCES TOLERANCE OF HUMAN ARTICULAR CHONDROCYTES

TAKAKURA, H.I, TANAKA, S.I, TACHIBANA, M.I, UENO, D.I, NAKAMURA, M.I, IZAWA, T.I, HOJO, T.I

1: Doshisha University

Introduction Thermotherapy has been applied to various joint diseases and injuries to alleviate their symptoms. Indeed, heat stimulation (HS) to an articular cartilage increased expression of cartilage matrix genes and heat shock protein 70 (Hsp70) gene, suggesting a protective effect in chondrocytes (Hojo et al., 2003; Tonomura et al., 2007). Although one of HSP70's roles is to protect cells against changes in the external environment, it is unknown whether chondrocytes gain higher tolerance to external stress after HS. Therefore, the purpose of this study was to evaluate the influence of HS-induced increase in HSP70 expression on human articular chondrocytes' tolerance to heat stress. Methods Cultured normal human articular chondrocytes (NHAC-kn, Lonza) were subjected to the 1st HS in a thermal bath (37, 39, 41, or 43 °C for 20 min) after 48 h of differentiation. Then, 24 h after the 1st HS, half of them were exposed to fatal stress (2nd HS at 45 °C) for 15 min. Cell viability and lactate dehydrogenase (LDH) activity were measured 8 h after 2nd HS. Twenty-four hours after each HS, Hsp70, proteoglycan, and type II collagen mRNA expressions were quantified by real-time PCR, and HSP70 protein level was measured by western blotting. Moreover, human articular chondrocytes were transfected with HSP70 small interfering RNA (siRNA) to determine whether knockdown of HSP70 led to decrease in the cells' tolerance. Results After the 1st HS, Hsp70 expression gradually increased with increase in temperature of the HS. Proteoglycan and type II collagen gradually increased until HS at 41 °C, whereas HS at 43 °C did not increase expression level of proteoglycan and type II collagen. Thus, the optimal temperature condition of the 1st HS was 41 °C. HSP70 expression level significantly increased 24 h after the 1st HS at 41 °C compared with that in untreated human articular chondrocytes. Moreover, human articular chondrocytes pretreated at 41 °C showed increased cartilage matrix gene expression and the most tolerance to the 2nd HS. The Hsp70 knockdown due to siRNA transfection attenuated the tolerance of articular chondrocytes to heat stress. Discussion Appropriate HS caused increase in HSP70 expression, leading to enhancement of articular chondrocytes' tolerance to heat stress. These results suggest that appropriate heat applications before physical activity could be useful for prevention of cartilage disorder and degeneration. THE NEW STANFORD 12-ELEMENTS VERSUS THE 12- ELEMENT AHA RECOMMENDATIONS AND ELECTROGRAPHIC SCREENING IN PREPARTICIPATION CARDIOVASCULAR EVALUATION OF COMPETITIVE ATHLETES

STOIAN, I.M., IONESCU, A., GEORGESCU, M., STOIAN, I.

*Emergency Institute of Cardiovascular Diseases Prof C.C. Iliescu, Bucharest, Romania, ** National Institute of Sports Medicine, Bucharest, Romania

Introduction. Preparticipation Cardiovascular (PPCV) examination: To compare the athletes' responses obtained by two questionnaires, the new Stanford 12-Elements (1) and the 12-Element AHA(2) regarding the athletes' personal, family history, suggestive for the CV diseases

responsible for unexpected sudden cardiac death. To compare the positive responses with the electrocardiograms according to the Seattle , European Society of Cardiology 2010, "Refined" criteria (3,4,5). Methods. PPCV in 2015: 357 athletes (285 M, 79.8 %), 21 ± 3yo. Caucasians. Sports: rowing, canoeing, football, athletics. All athletes responded the 12- Stanford (questions: 11, personal;1 physical exam) and 12-AHA (questions: 8, personal; 4, physical exam). ECG athletes, interpreted using the 3 criteria sets. The Stanford, AHA positive responses , analysed and compared with the ECGs data. Physical exams all athletes. Specific tests when required. Results.357 athletes responses. 45(12.6% positive): Stanford 35 (77.7%), AHA 10 (22.2%; of which, 6 Stanford positive). 22 (48.8%) of 45 positive responders had CV diseases (cardiomyopathy, 2; anomalous origin coronary artery,1; Brugada tip1, one; WPW,3; complex premature ventricular contraction,15). Training unrelated ECG: Seattle , 22 (100%); ESC 10 (45.5%), Refined criteria 22(10%) athletes. Discussion. The Stanford 12-Elements questionnaire is more specific compared to 12- Element AHA, pointing questions regarding the athletes' symptoms and past medical records. The ECG Seattle and Refined criteria support the Stanford questions. References 1.Tim P Dunn et al. THE INFLUENCE OF SLOW JOGGING AT WALKING SPEED ON THE SALIVARY AMYLASE ACTIVATION AND EXERCISE INTENSITY

KUDO, H., TANAKA, S.

Mejiro University

Introduction The slow jogging at walking speed is one of the beneficial methods for preventive help of lifestyle-related diseases. (Kitajima Y, Sasaki Y, Tanaka H, 2014) The slow jogging also is known as safety exercise for middle-aged and aged. The salivary amylase has been known as one of the stress biomarker (Yamaguchi, 2007) The purpose of this study were to compare with the exercise intensity, rating of perceived exercise(RPE), blood pressure, and saliva amylase activation between slow jogging and walking with same speed. Methods This study comprised 23 healthy male volunteers. All volunteers performed 30min of treadmill walking and jogging with 5km/h speed. The slow jogging and the walking practiced at interval of a week. The exercise intensity was calculated from heart rate with Karvonen Formula during treadmill walking and jogging. The RPE was measured every 2min during treadmill walking and jogging. The blood pressure, salivary amylase activation were measured at time of pre-exercise, immediately after exercise, and 30 minutes after exercise. The salivary amylase activation after exercise was quantitated by the amount of change from pre-ex value. Result The exercise intensity and the RPE on the slow jogging showed high value from the walking significantly (<0.05). The salivary amylase activation of the slow jogging and the walking had mean amount of change of 8.6+/-26.0KU/L and 6.5+/-24.3KU/L respectively, before immediately after exercise. The salivary amylase activation after 30min after exercise of both exercise also showed mean amount of change of 29.4+/-45.5KU/L and 13.3+/-23.7KU/L respectively. These values of the amounts of changes of salivary amylase activation were statistically significant different between the slow jogging and the walking. On blood pressure were no significant different between the slow jogging and the walking. Discussion Although the RPE of the slow jogging showed a high value from the walking significantly, the scale of RPE was under "very light". Therefore this result suggested the slow jogging was an exercise that was easy to continue. In addition, exercise intensity of the slow jogging showed effective aerobic exercise level for health. Therefore this result suggested the slow jogging could be a promising exercise method to prevent of lifestyle-related diseases. However it was necessary to pay attention to a stress biomarker. Reference Kitajima Y, Sasaki Y, Tanaka H. (2014). Journal of Running Science, 25(1), 19-27. Yamaguchi M. (2007). Folia Pharmacologica Japonica, 129, 80-84.

THE EFFECTS OF ACUPUNCTURE ON ISOKINETIC EXERCISE

KANEKO, Y.1,2, KIME, R.1, FURUYA, E.2, TSUNODA, N.3, HAMAOKA, T.1

1: Tokyo Medical University (Tokyo, Japan), 2: Kuretake College of Medical Arts and Sciences (Tokyo, Japan), 3: Kokushikan University (Setagaya, Japan)

Introduction Previous review reported that acupuncture has recently emerged as alternative medical enhancer of human physical performance (Ahmedov, 2010). The aim of this study was to examine the effects of acupuncture stimulation on isokinetic exercise of knee extensors. Methods Subjects were thirteen competitive triathletes (age: 22 +/- 3 yrs, height: 173.0 +/- 5.3, weight: 64.5 +/- 3.0). They performed repetitive isokinetic knee extension/flexion exercise (5 sets of 30 repetition, angular velocity: 60°/s, 3 min rest between each set) after 1) no stimulation as control (Cont), 2) acupuncture stimulation on quadriceps (WHO-SP10, ST34) (acuQ), and 3) acupuncture stimulation on lumbar region (WHO-BL24, BL26) (acuL). Electromyographic (EMG) activities of the rectus femoris (RF), the vastus lateralis (VL), and the vastus medialis (VM) muscles were collected and integrated (iEMG). Peak torque and total work were also observed. Rate of changes of those indexes from the first set were evaluated. Results There were no significant differences on iEMG, Peak torque and total work among groups at the first set of exercise. In Cont group, RF was significantly decreased at fourth and fifth set compared to the first set (-39.35, -53.6%, respectively; $p<0.05$) and VL was also decreased at fourth set (-61.7%; $p<0.05$) while no significant change of iEMG was observed in acuQ group. Peak torque of each group did not change significantly. There was a significant difference in total work between Cont and acuL at the fifth set (-9.6%, 6.2%, respectively; $p<0.05$). Discussion These results suggested acupuncture stimulation on the muscles prior to the isokinetic exercise affected neuromuscular function. Moreover, it was suggested that acupuncture stimulation did not influence on the change of peak torque, but was effective when applied on lumbar region, to prevent the fatigue caused by repetitive heavy exercise and sustain generating the power on knee extensor. These results partly agree with previous studies (Hübscher et al., 2010; So et al., 2007; Toma et al., 1998) although they examined the data detected by isometric exercise and the acupuncture points varied. Acupuncture stimulation increases oxygenation at both local (stimulated) and distant (not stimulated) area in the same innervation (Kaneko et al., in press). It is considered that the acupuncture stimulation lead more appropriate delivery of arterial blood flow into deoxygenated muscles so that it could help the recovery during resting period between the repetitive isokinetic exercises. AMETROPIA/VISUAL DEFICITS IN COMPETITIVE SPORTS – AN UP-TO-DATE STOCK TAKING

JENDRUSCH, G., OERTZEN-HAGEMANN, V., BUßMANN, C., PLATEN, P.

Ruhr-Universität Bochum

Introduction Former investigations showed that about 20% of all elite athletes who have been examined in the context of visual performance diagnostics exert their sport ametropic/with visual deficits (Jendrusch, 2008), although it is known that considerable visual reductions are leading to uncoordinated movement, even if motion sequences are automated. Nevertheless regular and meaningful visual tests for the analysis of the multidimensional visual performance and the detection of ametropia are only integrated in the health or performance diagnostics of few sports. Aim of the present study was to analyze current data of German elite athletes concerning ametropia or different parameters of visual performance; especially considering parameters that are also tested by optometrists or ophthalmologists. Methods The Vision Test Battery includes visual parameters like visual acuity, refraction error (nearsightedness/myopia or astigmatism), contrast sensitivity, stereoscopic perception of depth and color perception. The study focusses on a retrospective analysis of cross-sectional eye test data from different German national teams or first division athletes ($n=553$; age: 21.0 ± 4.0 years) which were collected in the annual routine health check during the last three years (2013-2015). Results About 27.5% of athletes use glasses or contact lenses in their daily life. 33.3% of athletes (women=29.3%; men=37.7%) with ametropia are practicing their sports without an optical correction. On one hand, there was a lack of awareness about the effect of visual performance on sporting performance, on the other hand the correction used was unsuitable to go in for sports or correction was poor in relation to wearing comfort. The median of the (monocular) visual acuity is about 1.85 for men and 1.80 for women (with maximum-values considerably above 2.50). Altogether 22.6% of athletes (women=21.8%; men=23.0%) are detected as ametropic and thus in need of correction. 7.0% of the athletes tested (women=4.3%; men=8.8%) had deficits in depth perception; 7.5% of the men showed a color asthenopia (red-green). Conclusion Vision has a crucial importance for movement control and balance regulation and helps anticipating fast movements in ball games as well as potential accident risks, e.g. in one-on-one-situations in football. The rate of ametropia is still high and shows that regular eyesight tests are necessary in competitive sports and should be an inherent part in health diagnostics in order to be able to detect and – subsequently – correct visual deficiencies at an early stage. References Jendrusch, G. (2008). Leistungen des visuellen Systems im Sport. Zeitschrift für praktische Augenheilkunde & Augenärztliche Fortbildung (ZPA) 29(6): 239-247.

CHANGE IN THE MUCOSAL IMMUNE FUNCTION ON A SINGLE WATER POLO GAME.

HANAOKA, Y., SHIMIZU, K., MURASE, Y., TAKEUCHI, K., YAMANAKA, Y., HIRAOKA, H., KIMURA, F., TAKAGI, H., KONO, I., MIYAMOTO, T., WATANABE, K., AKAMA, T.

University of Tsukuba

Introduction In the field of athletics, the risk of upper respiratory tract infection (URTI) is one of the most important problems in athletes. Salivary human beta-defensin 2 (hBD2) have anti-virus activity, thereby preventing URTI. However, there is no information on the response to hBD2 after the game. The aim of this study was to examine salivary hBD2 and secretory immunoglobulin A (SlgA) responses to a single water polo game. Methods 9 college water polo players (20.6 ± 0.4 years) participated in this study. They played a single water polo game. Saliva samples were collected pre game (pre), post game (post), post 2 h, and post 4 h after the game. hBD2 and SlgA concentrations were measured by the enzyme-linked immunosorbent assay. The total protein concentration was determined by the Pierce 660nm Protein Assay. The hBD2 and SlgA data were expressed as relative to total protein concentration (hBD2/TP, SlgA/TP, respectively). The visual analogue scale for subjective fatigue was used at the same points as sample collections. Results Mean salivary hBD2/TP at pre, post, post 2h, and post 4h were 4.5 ± 0.8 , 2.6 ± 0.4 , 3.1 ± 0.6 , 3.1 ± 0.6 pg/mg respectively ($p < 0.05$; pre vs. post). Mean salivary SlgA/TP at pre, post, post 2h, and post 4h were 122.9 ± 12.3 , 99.53 ± 14.0 , 78.7 ± 11.3 , 88.1 ± 7.4 ng/mg respectively ($p < 0.05$; pre vs. post 2h). Subjective fatigue significantly increased after the game until post 4h compared with pre ($p < 0.05$; pre vs. post, post 2h, post 4h). Discussion In this study, mucosal immune system mediated by hBD2 and SlgA might be impaired by a single water polo game. These findings might contribute to development of markers to oral immunity in other athletes or in different environment. However, further study is required to determine relationship between variation in immune markers and susceptibility to URTI in athletes. In conclusion, a single water polo game could impair oral immunity, particularly salivary hBD2/TP and SlgA/TP.

LOW BACK PAIN INCIDENCE AND RELATIONS TO MOTIVATION AND PERSONALITY TRAITS IN CROATIAN ROWERS

MLADEN, M., KOSOVIC, O.

Faculty of Kinesiology

Introduction Low back pain (LBP) is a common complaint in the rowing population (Gilchrist, 1983; Leo, 2015; Searge et al., 1990). There is a high prevalence of LBP in rowers at all training levels. However, very few studies have reported an effective management strategy to reduce LBP in these athletes (Leo, 2015). This may be due to the multidimensional nature of LBP that ranges from physical, psychological, social and lifestyle. The aim of this study was to determine whether personality traits, identified by the Eysenck personality questionnaire (EPQ) and level of motivation, identified by two test General achievement motivation (GAM) and Sport achievement motivation (SAM), in rowers with LBP are similar to those of a rowers without LBP. Methods The medical interview were performed on a group comprised of 19 rowers (age: 18.2 ± 2.6 years; height: 184.3 ± 6.3 cm; weight: 80.9 ± 8.86 kg), members of the Croatian national team during spring preparation camp. All rowers were asked to complete three test: two test which measure level of motivation for general (GAM) and sport (SAM) achievement and one test which measure personality traits (EPQ). Rowers were divided in two groups according the incidence of low back pain. Descriptive analysis as well as univariate analysis were processed using the statistical package Statistica 13. Results Incidence of LBP divided rowers in two groups. One group with incidence of LBP included 10 (52.6%) rowers. Univariate analysis didn't show differences in any variable within these two groups. Discussion Incidence of LBP among this group of Croatian rowers is found to be at level usually reported in numerous studies. Konative aspect of rowers as well as motivation are not characteristics which differ rowers according to LBP incidence. Taimela et al (1999) demonstrated that lumbar fatigue significantly impaired the ability of subjects to sense the position of their trunks when in flexion. For rowers, this may mean that, as they become fatigued, they may not be aware that they are moving into a more flexed posture. Beside all modalities and time spending in specific rowing work, with aim of prevention of low back pain relevance should be paid to metabolic intensities as the body reacts on mechanical work intensity. THE EFFECTS OF MAXIMAL EXERCISE INTENSITY ON FREE RADICAL, ANTIOXIDANT CAPACITY AND EPOC

HAN KYO, S., YI SUB, K.

ShinHan University

The purpose of this study was to investigate of maximal exercise intensity on free radical, Antioxidant Capacity, oxygen consumption and EPOC(excess post-exercise oxygen consumption) in Judo Players of different weight class. For this study, participants were divided into two groups, lightweight group(n=8) and heavyweight group(n=8). The analyzed data brought about the following results by using independent t-test with SPSS 16.0. The results of the research were as follows. First, according to the Free radical test, lightweight group was increased higher than heavyweight group at pre-exercise, post-exercise and 30 minutes of recovery time. And lightweight group and heavyweight group show statistical significant difference at 10 minutes of recovery time. Second, according to the Antioxidant Capacity, lightweight group and heavyweight group show statistical significant difference at post-exercise and 10 minutes of recovery time. Third, lightweight group and heavyweight group show statistical significant difference at post-exercise and 10 minutes of recovery time. Fourth, EPOC, lightweight group and heavyweight group show statistical significant difference. From these results, heavyweight judo player's EPOC period longer than lightweight judo player. However, antioxidant capacity was lightweight judo player higher than heavyweight judo player. Therefore author deems that judo player of different weight class have need to different rest way and exercise treatment.

CHANGES IN LOWER LIMB MUSCLE ACTIVITY IN SOCCER PLAYERS WITH FUNCTIONAL ANKLE INSTABILITY DURING A DIAGONAL SINGLE-LEG DROP LANDING

KUNUGI, S., MASUNARI, A., MIYAKAWA, S.

university of tsukuba

Introduction Ankle sprain is one of the most common injuries in soccer players. Functional ankle instability (FAI) is residual symptom often develop as a result of ankle sprain. Patient with FAI has postural control deficits at ankle joint. Time to stabilization (TTS) that is used to evaluate the postural control is the time it takes for an individual to regain to single-leg stability after landing. Reduction in peroneus longus (PL) activity was accompanied by inverted position of the ankle joint from pre landing period (Delahunt et al. 2006). This can cause that patient with FAI take longer TTS than healthy people (Ross et al. 2005). However, peroneus brevis (PB) activity is not clear during landing period. Methods Twenty-one male collegiate soccer players participated in this study. They were classified into 2 groups using Cumberland ankle instability tool Japanese version (CAIT-J)(Kunugi et al. 2016). 11 FAI group (age 18.2 ± 04 years, CAIT-J 21.0 ± 3.1) and 10 control group (age 18.7 ± 0.8 years, CAIT-J 30.0 ± 0.0) were instructed to land from a box of 30-cm high into anterolateral direction, stabilize as soon as possible, and remain as motionless as possible in a single-leg stance for 20-s. We calculated TTS mediolateral (TTSM) using a force plate. We recorded the muscles activity from the PL, PB, tibialis anterior (TA), gastrocnemius medialis (GM) during drop landing. Data relating to the period 500-ms pre-initial contact (IC) and 500-ms post-IC were analyzed to compare to difference between FAI and healthy group using independent two-sided t-test. α was set at 0.05. Results There was significant difference for TTSM between FAI group (mean 4626.3 ± 347.4-ms) and control group (mean 4282.1 ± 282.4-ms). Reduction in PL, PB, and TA activity was founded in FAI group during the time 1-ms–11-ms post-IC, from 214-ms–31-ms pre-IC, and 68-ms–85-ms post-IC, respectively ($p < .05$). Discussion Male collegiate soccer players with FAI had postural control deficits and low muscle activity in PL, PB, and TA during single-leg landing. This reduction in muscle activity may be caused by proprioceptive deficit at ankle joint. It is clear that PB activity has reduced in participants with FAI during pre-IC. MYOELECTRICAL IMPEDANCE SYSTEM FOR ASSESSING MUSCLE INJURY

CHOI, J.W.

1.Soonchunhyang University, 2.Korean National University of Education

Bioelectrical impedance analysis produces phase angle, resistance, reactance and impedance, which can be used in assessing whole body composition and segmental body composition. We design myoelectrical impedance system based on the segmental bioelectrical impedance parameters for assessing muscle injury and muscle health status. We investigated the effects of degree and prognosis of muscle injury on bioelectrical impedance parameters. Phase angle and reactance decreased after muscle strain and these parameter increased according to the regeneration and healing process. These findings imply that changes in R reflect fluid accumulation, and fluctuation in Xc and PA highlight disruption of cellular membrane integrity and injury. Therefore, segmental BIA (or myoelectric impedance system) may provide a powerful outcome measure for assessing the healing process of muscle injury

EXCESSIVE EXERCISE HABITS IN MARATHONERS AS NOVEL INDICATORS OF MASKED HYPERTENSION

SHIN, D.1, KANG, D.1, KIM, E.2, KIM, H.2, KIM, Y.3

1.Soonchunhyang university, 2. Korea National University of Education, 3. Sanggye-Paik Hospital

Although appropriate levels of exercise have been found to improve vascular endothelial function and decrease blood pressure, an excessive amount of exercise increases arterial stiffness and the cardiovascular risk. Here, we aimed to assess whether the exercise characteristics of amateur, middle-aged marathoners with high blood pressure can be used as a novel indicator of masked hypertension. The subjects comprised healthy, middle-aged (≥ 40 -years-old) marathoners, who had participated in marathons for at least 3 years, and regularly trained 2 times per week. A total of 571 subjects were assigned to a high blood pressure group (HBP; n=214), with a resting systolic blood pressure (SBP)/diastolic blood pressure (DBP) of $\geq 140/90$ mmHg, or a normal blood pressure group (NBP; n=357), with a resting SBP/DBP of $< 140/90$ mmHg. A graded exercise test was used to examine the hemodynamic response and cardiac events, and the personal exercise characteristics were also recorded. Although no difference in the personal characteristics were observed between the groups, the frequency of alcohol consumption was significantly higher in the NBP than in the HBP ($p < 0.001$). No difference in the inHRrest, HRmax, Re-HR 1–2 min, ST depression, or arrhythmia, were observed between the 2 groups, although the SBPrest

($p<0.001$), DBPrest ($p<0.001$), SBPmax ($p<0.001$), DBPmax ($p<0.001$), VO2max ($p<0.05$), MTE ($p<0.05$), PPrest ($p<0.001$), and PPmax ($p<0.001$) were significantly higher in the HPG than in the NPG. The number of marathons completed and exercise frequency were not significantly different between the groups. However, the marathon history was significantly longer in the NPG than in the HPG ($p<0.01$), and the exercise intensity and time were also significantly greater in the NPG than in the HPG ($p<0.01$, $p<0.05$, respectively). The marathon completion duration was significantly shorter in the HPG than in the NPG ($p<0.05$). Among middle-aged amateur marathoners, despite the presence of a shorter history of exercise, individuals with high blood pressure showed a higher frequency of alcohol consumption and more excessive exercise characteristics than individuals with normal blood pressure. If the individuals exhibit high blood pressure during rest as well as exercise, the exercise characteristics could be used as a novel indicator for masked hypertension.

SURVEY OF OBSTRUCTIVE SLEEP APNEA IN JUDOISTS

IMAI, T., WATANABE, K.

University of Tsukuba

Obstructive sleep apnea (OSA) are caused by collapse of the pharynx during sleep¹. OSA symptoms include excessive daytime sleepiness, aggressiveness, inattention, headache, poor memory and difficulty in socialization. Previous study reported that sleep quality relate to sports performance. These OSA symptoms may drop athlete conditions and performance because OSA reduces sleep volume and quality. In judoists, especially in heavy weight class, their physical feature may be a high risk of OSA. However, it was unknown their sleep condition of judoists. We investigated that sleep condition of judoists with questionnaire and polysomnography. Purpose The purpose of the present study was to examined the state of OSA in judoists Methods Subjects were men of 28 judoists member in university. They belonged to 5 weight categories in judo. We distributed 28 questionnaires to ask the sleep conditions, epworth sleepiness scale (ESS), which is index of OSA in judoists. Then we collected 28 question papers from judoists, and collected 100% questionnaire. Afterward we analyzed questionnaire and picked 8 judoists. To confirm the OSA, 8 judoists were measured with the polysomnography (PSG) during sleeping. Results 4 judoists were more than 11 ESS scores. 2 judoists answered that they snored during sleeping every night. And 14 judoists answered that they sometimes snored at night. 8 judoists had an experience of arousal during sleeping. 8 judoists were measured sleeping state with PSG. 2 judoists showed reduction of oxygen desaturation, and more than 5 apnea hypopnea index. Discussion OSA incidence rate of judoists was 7%. This incidence was higher than general investigation, which was found in about 2% of the japan population. Although one judoists of OSA belong to heavy weight class, and the other judoist didn't belong to it. The judoist might have facial characteristics that are associated with OSA. Some judoists had factors of sleep disorder. We need further research on the sleep conditions in judoists, since we couldn't investigate the reason why judoists had factors of sleep disorder. Conclusion In judoists, rate of OSA prevalence might be high compared with other player and general people. References 1. Bradley TD, Floras JS. FE ANALYSIS OF KINETICS AND KINEMATICS OF POSTERIOR CAPSULAR CONTRACTURE DURING SHOULDER ABDUCTION

GHIASI, M.1,2, VAZIRI, A.1, NAZARIAN, A.2, PATEL, N.1,2, MOUSANEZHAD, D.1, GOEBEL, R.3

1 Northeastern University (Boston, USA); 2 Beth Israel Deaconess Medical Center and Harvard Medical School (Boston, USA); 3 Qatar University - Sport Science Program

Introduction Posterior capsular contracture of shoulder was reported as a significant source of shoulder pain and restriction to shoulder kinematics including internal rotation and abduction. In our previous study, we investigated the effects of posterior capsular contracture during passive abduction of an intact cadaveric shoulder through a simulated plication for 6 cadaveric cases. In the current study, we carried out a finite element (FE) analysis to deduce the stress field and contact path during the passive abduction of shoulder in normal and posterior contracture (plicated) statuses. Method In our previous study, we described the posterior capsular contracture was simulated through plication and drawing the humeral head closer to the glenoid. Then, the glenohumeral motion was measured for 6 cadaveric cases during shoulder abduction. In the current study, using computational tomography (CT) images, the geometry of glenoid and humeral head for all cadaveric cases was prepared and meshed for FE analysis. In the FE analysis, the previously detected motion data of humeral head on the glenoid joint was the model input. Contact path and stress field in the contact region of glenohumeral joint were analyzed by conducting a dynamic explicit FE analysis. Result As the kinematic results, the contact path in 3 x, y and z direction were compared for both normal and plicated states which no significant difference can be seen in the kinematics of two states. In the kinetic perspective, the joint reaction forces and stress field of humeral head and glenoid were calculated and compared for both normal and plicated groups. The results showed that in the humerus axis direction, the joint reaction force direction and magnitude changed as more compression applied to the glenohumeral joint. However, in normal direction to the humerus axis, there were no significant changes in the reaction forces. Discussion As an important outcome of this study, the experimental methods and FE analysis were combined together to analyze the kinematics and kinetics of posterior capsular contracture through a simulated plication. The FE analysis helped us to understand better the differences of shoulder kinetics and kinematics including contact path, stress field, reaction forces and joint compression and stability under both normal and plicated conditions. THE SYNERGISTIC EFFECT OF ACUPUNCTURE USING PRESS TACK NEEDLES AND RESISTANCE TRAINING IN YOUNG ADULTS: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

TERADA, K., IKEDA, M., KOBAYASHI, Y., NAKATANI, T.

Tenri University

Introduction The efficacy of acupuncture in clinical studies is difficult to evaluate using double-blind tests (Streitberger et al., 1998). Press tack needles (PTNs) are small needles that are fixed with adhesive plaster and have the advantage of easy insertion into the epidermis, allowing them to be used during exercise. Miyazaki et al. (2009) performed a double-blind, randomized, controlled trial to investigate the effect of PTNs on lower back pain. In this study, a double-blind, randomized, placebo-controlled trial was performed to clarify the synergistic effect of acupuncture using PTNs and resistance training programs in young adults. Methods Sham PTNs, which looked like PTNs but without a needle tip, were developed by an acupuncture needle manufacturer. Twenty-two healthy young men aged between 22 and 23 years (21.7 ± 0.6 years) were randomly and equally assigned to two groups, namely the resistance training plus "real" acupunc-

ture with PTN intervention group (AG; n = 11), and the resistance training and "placebo" acupuncture intervention groups (PG; n = 11). Both the real and sham needles were applied to two meridian points (ST32 and GB31) in the lower limb area. The AG participants underwent structured acupuncture using PTNs, and their exercise regimen consisted of home-based resistance training of the lower limbs (squat) using their own bodyweight. They measured exercise intensity with the OMNI Resistance Exercise Scale (OMNI-RES, on a 10-point scale) and performed repetitions until they reached a perceived exertion intensity of 8 of 10 for 4 weeks. The PG participants underwent structured placebo acupuncture and the same resistance training program. The outcome measures were body composition, isometric peak torque in knee extension, vastus lateralis muscle thickness, 30-s chair-stand test, vertical jump, and rebound jump index. The evaluation parameters such as subjective leg pain caused by delayed-onset muscle soreness were measured on the 100-mm horizontal visual analogue scale. A Kappa statistic value was used to evaluate the validity of the PG. Results The Kappa statistical value was -0.36. After intervention, we observed a statistically significant two-factor interaction between the AG and PG groups in the left ($F = 18.3$, $p < 0.001$) and right isometric peak torques ($F = 18.3$, $p < 0.001$) in knee extension and vertical jump ($F = 5.9$, $p < 0.05$). However, no statistically significant synergistic effect of "real" acupuncture using PTNs and resistance training was observed in the other measures. Conclusion This result suggests that the effect of exercise may be enhanced by intervention with concurrent acupuncture using PTNs. Training and Testing

COMPLEX TRAINING: THE EFFECT OF EXERCISE SELECTION AND TRAINING STATUS ON POST-ACTIVATION POTENTIATION IN RUGBY LEAGUE PLAYERS.

SCOTT, D.1, MARSHALL, P.1, DITROILO, M.2

University of Hull

1. Department of Sport Health and Exercise Science, University of Hull, UK. 2. School of Public Health, Physiotherapy and Sports Science, University College Dublin, Ireland. Introduction Complex training is underpinned by post-activation potentiation (PAP) which theorises that the explosive capability of a muscle is enhanced following a near maximal voluntary contraction. An individual's response to complex training differs due to factors including the recovery interval, exercise selection and training status (Tillin and Bishop, 2009). The aim of this study was to compare the PAP response of the hexbar deadlift (HBD) and back squat exercises (BS) in professional and amateur rugby league players. Methods Ten professional and ten amateur rugby league players performed two experimental sessions. Participants performed a vertical countermovement jump before and, 2, 4, 6, 8, 10, 12, 14 and 16 minutes after a conditioning activity (CA). This comprised of 1 set of 3 repetitions at 93% 1RM of either HBD or BS. A force platform was used to determine peak power output (PPO), force at PPO, velocity at PPO and jump height of each countermovement jump. The surface EMG of the vastus lateralis, rectus femoris, tibialis anterior and gastrocnemius medialis of each participant's dominant leg was recorded during each countermovement jump. Ten participants performed a control trial without a CA. For all variables, the post-CA jumps were compared to baseline. Results PPO improved for the HBD at 2 ($p < 0.001$), 4 ($p = 0.01$) and 6 minutes ($p = 0.002$), but was not improved for BS. PPO decreased for the control group at 16 minutes ($p = 0.016$) but did not for HBD or BS. For both HBD and BS force at PPO improved at 4 minutes ($p = 0.014$). For both HBD and BS velocity at PPO decreased at 16 minutes ($p = 0.004$). Velocity at PPO decreased for the control group at 14 minutes ($p = 0.05$) but did not for HBD or BS. There were no changes in jump height or EMG variables. There were no differences between professional and amateur players. Discussion Results of this study suggest that HBD elicits PAP earlier than the BS. HBD is an effective alternative to BS as it is a safer, less technically demanding exercise which enables greater loads to be lifted (Swinton et al., 2011). Complex training appears to be a suitable training modality for professional and amateur rugby league players. Methods of altering the force-velocity curve during the CA should be investigated to make the movement more specific to the plyometric activity (Crum et al., 2012). THE DIAGNOSTICS OF ED ELEMENTS IN COMPETITIVE SPORT

MARIUSZ, O., SZMATLAN-GABRYS, U., GABRYS, T., STANULA, A.

University School of Physical Education in Cracow

THE DIAGNOSTICS OF SELECTED ELEMENTS IN COMPETITIVE SPORT (ILLUSTRATED WITH AN EXAMPLE OF POLISH WOMAN BASKETBALL FIRST LEAGUE) Introduction The basic element of controlling training process is a verification of effectiveness and accuracy of used methods in purpose of supervising training and sport competition (Gabrys and Kosmol 2000, Neuman et al. 2005, Ozimek 2007, Zemkova 2008). The aim of this papers is to present the selected elements of diagnostics in competitive sport with special attention to the determination raining indicators in selected areas of motor preparation of team members of Polish basketball woman first league. Methods The research included 15 members of Polish woman basketball of first league. The program of the research was as follows: Warm-up. Psychomotorics on a large field (before and after effort) – a test evaluating reaction and orientation speed performed by legs on a field of 3 meters (a square; Fitro Agility Check). Evaluation of lower limbs (before and after effort) – tests: SQUAD JUMP, CMJ – Counter movement jump with and without backswing and DROP JUMP. Aerobic capacity – BIP TEST – every 3 min. increase in load and biochemical examination (K4b2 Cosmed; BIOSEN C-line). Results The results point to a direct aim of conducted research and determine the effect on the controlled indicators on the effectiveness of training, comparisons between participants, evaluation of oxygen consumption, determination of the kinetics of oxygen deficit and oxygen debt as well as determination of the level of lactate at different moments of effort. The results of this research provide direct information on the state of preparation and its possibilities related to the conducted control of training effects. Discussion The scope of training control and its effect should include a wide range of observations. Their most important elements include: biochemical supervision, physiological supervision of anaerobic and aerobic capacity in laboratory conditions as well as conditions specific to a particular sports discipline, physical fitness and specialist preparation regarding power, force, speed, speed and strength endurance as well as the analysis of a sports training conducted in a training series (Gabrys and Kosmol 2000, Zemkova 2008). Numerous questions related to success and failure of a sportsperson can be answered by a sports training diagnostician. What is more, comprehensive and systematic diagnostics supports both the work of a player and a trainer (Neuman et al. 2005, Ozimek, 2007). EFFECTS OF HIGH INTENSITY INTERVAL TRAINING DURING THE TRANSITION PERIOD IN FOOTBALL PLAYERS SUB-19

ROMERO MORALED A., MARTOS VARELA, S.2, DA SILVA GARCÍA-RIEGO, R.3, GALLARDO, J.1, JIMÉNEZ, V.1, DE LA TORRE, P.4, PORCEL, D.2, PAREDES HERNÁNDEZ, V.1,2

Universidad Camilo José Cela

Introduction Currently exists a growing interest in the application of high-intensity interval training (HIIT) in football (Buchheit et al. 2013). HIIT has shown efficiency to improve performance variables in team sports (Iaia et al. 2009). However, little research has been reported regarding the effects of HIIT on performance after winter transition period in football. Therefore, the aim of this study is to compare the effects on performance versus traditional training HIIT during the winter transition period in football players U19. Methods A total of 40 players (20 players U19 of premier league and 20 players of second league) of 17.8 ± 0.4 and 16.8 ± 0.4 years respectively performed a program of 3 sessions during the week of winter transitional period (7 days). The HIIT group, performed a high-intensity interval training that consisted of 5 repetitions of 15 seconds at 140% of your Maximum Aerobic velocity (VAM) followed by a period of 45 seconds at 60% VAM, plus 5 core exercises (2x30''). NO-HIIT group, performed 30 minutes of continuous running at 60% of maximum heart rate. The training sessions were monitored with Runtastic mobile application and a training log. The performance were measured before and after the transition period: countermovement jump test (CMJ) using MyJump, squat power test by SmartCoach and body composition variables (body mass and fat percentage). Student's t test was performed to analyze the differences for independent variables with software SPSS v.20 for Macintosh. Results The change percentage for the power in half squat ($p=0.05$) and CMJ ($p=0.03$) was significantly negative for NO-HIIT group. After the transitional period, both groups showed significant intra-group increases for fat percentage (HIIT group: 6.37 ± 7.9 ; NO-HIIT group: 3.80 ± 5.75 ; $p=0.01$ and 0.02 respectively). Discussion The main finding of the study was that HIIT group obtained favorable results for power variables. A similar study showed that football players achieved to maintain the values of VO_{2max} during the transitional period, with a lower density of HIIT sessions (Slettalokken et al. 2014). Other studies have shown the effectiveness of HIIT training versus continuous training for both VO_{2max} and power variables in young players (Sperlich et al 2011; Pilianidis 2013 et al.). These results could show that intermittent high intensity training can be a useful method and recommended to maintain or even improve variables such as average power in squat and CMJ during the transitional period. Conclusion The HIIT group showed significantly favorable results for the half squat and power CMJ compared with NO-HIIT group. The fat percentage was significantly increased in both groups.

HEART RATE AND PERCEPTUAL ACUTE RESPONSES OF PRACTITIONERS DURING THE DIFFERENT MOMENTS OF CAPOEIRA CLASS

MOREIRA, S.R., BEZERRA, T.A., SOUZA FILHO, A.N., CAMARA, M.V.F., SOUZA, D.A., TEIXEIRA-ARAÚJO, A.A., CARVALHO, F.O.

Federal University of Vale do São Francisco (UNIVASF)

Introduction Among the sports eliciting acute cardiovascular adaptations, we can highlight Capoeira as a Brazilian martial art/dance that has spread worldwide (Silva et al., 2012). Objective To analyze the heart rate (HR) and perceptual acute responses of practitioners during the different moments of Capoeira class. Methods Sixteen physically active adults (10 male: 26.4 ± 5.2 y; 06 female: 30.3 ± 8.8 y) performed a Capoeira class with continuous monitoring of HR (ZEPHYR®), rate perceived exertion - RPE (Borg Scale 16 to 20), feeling scale - FS [+5 to -5] and perceived activation - PA [+1 to +6]. The Capoeira class composition, which lasted for 60', was from: a) 2' playing rhythm instruments; b) 2' singing songs; c) 8' to warm-up; d) 3 sets with 2' of ginga by 1' recovery each; e) 3 sets with 2' of technical movements by 1' recovery each; f) 12' with passive participation in Capoeira circle and; g) 1' of Capoeira game in the circle. The remaining time (23') was distributed in recovery between movements during the class. On different day a maximal incremental test in cyclogrometer (CEFISE®) was performed starting at 25W (Fem) and 50W (Male) with increments of 25W every 1' until exhaustion (50 RPM's), to anaerobic threshold (AT) and maximal power (P_{MAX}) determination. Results When compared to rest of total sample the HR (77 ± 13 bpm) increased ($P < 0.01$) from warm-up (102 ± 12 bpm) until Capoeira circle (135 ± 25 bpm), as well as differed from the total class average (117 ± 13 bpm). To verify the Capoeira class HR in relation to aerobic fitness, it was found that the total class average occurred at $80 \pm 10\%$ AT and $65 \pm 7\%$ P_{MAX}. The RPE shows increase ($P < 0.01$) from rest (8 ± 3 pts) to ginga (12 ± 2 pts), technical movements (14 ± 2 pts), Capoeira circle (14 ± 2 pts) and total class average (11 ± 2 pts). The other perceptual variables did not change ($P > 0.05$) from rest to different moments of the class, with FS keeping in the total class average at 3 ± 2 pts and PA at 4 ± 1 pts. Discussion The main finding of study was that a Capoeira class, characterized by its main movement (ginga), and by several others, as well as by moments for the musical rhythm with singing and playing characteristic instruments, acutely increase the HR and RPE in practitioners. These results suggest that Capoeira can be a physical activity strategy for cardiovascular adaptations. Besides, it is speculated from the modulation of the RPE and FS during the class, that Capoeira can be an important tool for adherence to an individual in the regular physical activity. Conclusion A single Capoeira class increase acute and significantly the HR and perceptual responses of practitioners. THE RELATIONSHIP BETWEEN PHYSIQUES AND PHYSICAL STRENGTH IN JUNIOR HIGH SCHOOL STUDENTS

MURAKAMI, K.

Kokugakuin Univ

1. Introduction Junior high school age is an acceleration period in physical growth and development. Especially, the cardiorespiratory function is significantly improved in this period. This study is to examine the relationship between the change of physiques and physical strength in junior high school students. We especially focused on endurance and instantaneous speed as physical functions. 2. Methods The data was collected from 110 junior high school students (60 males and 50 females). We measured their body height, body weight, and records of long-distance running (male:1500m and female:1000m) and short-distance sprint (50m) for three years. We collected the data every year in spring. We used ANOVA to find the mean difference among three different grades, and also used t-test for comparing two groups. The relationship between the change of physiques and two records of running was examined by correlation analysis with Spearman's coefficient. We adopted significance level of less than 5% for all the tests in this study. 3. Results and Discuss-

sion According to Sakamoto(2004), the paces of development in physiques and physical skills vary considerably from person to person in the period, from 13 to 14 years old, in both male and female. We could see several differences regarding physiques and physical skills in this study. For example, as to short-distance sprint, the records have been improved with advancing age among male students, and there was a difference between first grade and second grade students among female students. We also could see strong correlation between body weight and long-distance running among all grades in male students, and among first grade and second grade in female students. In terms of the relationship between physiques and differences of physical strength among each grade, there was a significant relationship between the difference of body height and the difference of record of long-distance running among first grade and second grade students for female. 4. Discussion Physical growth has highly influenced on improving both endurance and instantaneous exercise performance in the junior high school period. Especially, we could see a remarkable tendency in the short-distance sprint. It can be very important for the junior high school students to consider the influences of the change of their body weight on exercise performance because they are still in the progress of physical development. THE LONG-TERM EFFECTS OF SPRINT INTERVAL TRAINING ON PHYSIOLOGICAL RESPONSE TO REPEATED MAXIMAL SPRINT CYCLING

HEBISZ, P., HEBISZ, R., ZATÓN, M.

University School of Physical Education

THE LONG-TERM EFFECTS OF SPRINT INTERVAL TRAINING ON PHYSIOLOGICAL RESPONSE TO REPEATED MAXIMAL SPRINT CYCLING Introduction While interval training is considered an effective modality for improving performance, there is a lack of data on the physiological adaptation to repeated sprint exercise over several months of training. The aim of the study was to compare the effects of two training strategies on cardiorespiratory response and work output in a sprint interval training-test in well-trained cyclists. Methods Twenty cyclists were randomized into two groups for 16 weeks of exercise training. Group E completed a traditional endurance training whereas the training of group I was modified to include sprint interval training (SIT) twice per week. Performance and physiological variables were measured by the SIT test on a Cyclus2 cycle ergometer (RBM, Germany) at three time points: pre- (T1), peri- (T2; 8 weeks), and post-intervention (T3; 16 weeks). The test involved a 20-min warm-up followed by three sets (S1, S2, S3; each separated by 20–30 min of active recovery) of four 30-s maximal bouts interspersed with 90-s recovery periods. Oxygen uptake ($\dot{V}O_2$), carbon dioxide production ($\dot{V}CO_2$), and pulmonary ventilation (VE) were measured using a Quark gas analyzer (Cosmed, Italy) and work output was determined. Data were aggregated for each set. Results Relative $\dot{V}O_2$ significantly increased in group I at T2 (39.3±7.1, 40.4±8.1, 40.7±7.4 l/l) in S1, S2, S3) and T3 (40.2±6.9, 41.2±6.7, 41.3±7 l/l) compared with T1 (35.4±6.7, 36.8±6.4, 37.6±6.3 l/l), respectively, whereas no significant differences were observed in group E across the time points. VE, $\dot{V}CO_2$ and work output had the same direction of change as $\dot{V}O_2$ for groups I and E. Discussion Many authors have suggested that interval and endurance training are two modalities that induce beneficial physiological adaptations as measured by incremental testing (Bouchard et al., 2011; Roxburgh et al., 2014). However, Sloth et al. (2013) indicate that endurance training alone is unable to further elicit improved performance in well-trained athletes. Our findings indicate that a combined endurance and interval training protocol is more effective in increasing cardiorespiratory response and work output to repeated sprint exercise than conventional endurance training alone in athletes with several years training experience. At the same time, extended interval training (above 8 weeks) shows a plateau effect although effective in maintaining previously induced training adaptations. THE SPECIAL JUDO FITNESS TEST IN COMPETITOR PREPARATION DIAGNOSTICS DURING AN ANNUAL TRAINING PERIOD.

SZMATLAN-GABRY, U.1, GARNYS, M.2, GABRY, T.3, OZIMEK, M.1

1: AWF (Krakow, Poland), 2:4SportLab (Warszawa, Poland), 3:AJD (Czestochowa, Poland)

THE SPECIAL JUDO FITNESS TEST IN COMPETITOR PREPARATION DIAGNOSTICS DURING AN ANNUAL TRAINING PERIOD. Szmatlan-Gabrys U.1, Garnys M.2, Gabry T.3, Ozimek M.1 1: AWF (Krakow, Poland), 2:4SportLab (Warszawa, Poland), 3:AJD (Czestochowa, Poland) Introduction: A correlation analysis carried out between the values of capacity indicators, and special fitness, is a tool allowing us to determine the relationship and interaction between competitor preparation periods, and the appropriateness of the choice of supervision methods. (Franchini et al 2009) The aim of the research was to either confirm, or refute the hypothesis concerning the universal character of the SJFT in the evaluation of the preparation of the judoist. Methods. During the annual training period capacity indicators of 23 international sport level judoists aged 19-26, in 66-81 kg weight categories were registered. The subjects carried out three tests four times: Wingate Test with Pmax registration (W/kg, b.w) WTOTJ/kg, b.w) and IF(%), SJFT, registering index; during the treadmill Incremental Exercise the VO₂, VCO₂, VE , and HR were registered. (K4B2, Cosmed) The character and strength of the relationship between test indicators during the general preparation period (GPP), the special preparatory periods (SPP), and the competition period, were determined by means of a statistical analysis. Results. The statistically relevant correlations between the aerobic, anaerobic, and special capacity indicators divided the indicators into two indicator groups assigned to training periods. In GPP- SJFT, and VO_{2max} (r=.397, p.05), as well as IF (r=-.396, p.05), SPP- SJFT with WTOT (r=.411 p.05),and Pmax (r=.405 p.05), CP - SJFT with WTOT (r=.425 p.05), and IF (r=-.461 p.05) Discussion. The research did not confirm the universal evaluation of special preparation of the judoist by means of the SJFT (Franchini 2009) A lack of relationship was shown between aerobic capacity and SJFT in SPP, and CP , as well as with anaerobic capacity in GPP. The statistically relevant relationship between the SJFT index and aerobic metabolism which was indicated by the research by Franchini et. al. (2011) was not confirmed. In SPP, and CP, WTOT correlates with SJFT index. Periodically the IF value shows a relationship with SJFT index value. (GPP, and CP r= -.396, r=-.461, respectively). In GPP aerobic, and in SPP, and CP anaerobic training measures dominate. Then, there appears also relationship between IF, WTOT, Pmax, and SJFT index. It can be stated, that SJFT is a tool evaluating the special preparatory judoist during training periods characterized by a great deal of anaerobic training loads. In training periods in which judoist passes from metabolic, anaerobic training loads to metabolic aerobic ones, SJFT is not a good judoist evaluation tool. Grant RSA3 01753. COMPARATIVE ANALYSIS OF MEN'S AND WOMEN'S ATTACK IN ESTONIAN VOLLEYBALL CHAMPIONSHIP LEAGUE

STAMM, R., STAMM, M., TORILO, D., JAIRUS, A.

Tallinn University, Institute of Health Sciences and Sports

Introduction Do the attack tactics of men and women in the highest volleyball league of Estonia differ and how? Which is the tempo of attack and are more spikes or decoys used, and what is the efficiency of different types of attack in men's and women's games? **Methods** A total of 20 videos of men's and women's championship games of 2014/2015 were analysed, and the tempos and types of attacks were registered. The assessment of the tempo of attack was based on Selinger's classification which uses three categories: tempo 3 — a slow tempo when the attacker begins the steps of approach when the set ball has reached the highest point of its flight trajectory; tempo 2 — a medium tempo, the attacker begins the steps of approach when the ball has left the setter's hands, and tempo 1 — a quick tempo where the attacker performs the approaching steps before the setter touches the ball (Selinger, 1986). To determine the type of attack the distinction between vigorous attack and set attack or decoy was used. Data Volley and Volleysoft 6-3 statistics programs were used to estimate the efficiency of attack. Multinomial logistic regression was applied to analyse the attack actions that could differentiate male and female game profiles. **Results** The difference between men and women appears in tempo 3 and tempo 1, as men use tempo 3 or the slow attack least of all the tempos of attack (11.2%), which refers to the faster attack action in men's games and to the tendency to attack against one blocker or against a block with a hole in it. In women, however, tempo 3 attacks were more frequent than tempo 1 attacks. The results of regression analysis showed that in men's teams the opportunity to perform a tempo 1 attack compared to tempo 3 was 1.48 times greater than in the case of women. In the case of tempo 2 attack compared to tempo 3, in men the potential performance of tempo 2 is 1.8 times greater than in women ($p < 0.05$). The analysis of attack types revealed that both men and women use vigorous attacks in games more often than decoys. The difference between men and women lies in the relation between using the decoy and the spike. Women use the decoy in games 8% more than men do. **Discussion** Women's attack activity had lower proficiency than men's. Men gained a point from 46.2% of attacks, women — from 36.2%. For comparison, men's mean result in World Championship games in 2011 was 50.2% and in Brazilian women's Super League in 2012 38.7% (Costa, 2014). In conclusion, it can be said that in Estonian men's championship games tempo 1 attacks are used statistically significantly more often than in women's games. Men are more proficient at attack and use vigorous spike more often than women do. **References** Selinger, A., Ackermann-Blount, J. (1986) Arie Selinger's power volleyball. THE COMPARISON OF BONY STRUCTURES BETWEEN JAPANESE AND FRENCH POPULATION ACCORDING TO THE PHYSICAL ACTIVITY LEVEL.

IGUCHI, J.1, HOJO, T.2, FUJISAWA, Y.2

1:Kyotogakuen University (Kyoto, Japan), 2:Doshisha University (Kyoto, Japan)

Introduction It has been widely noted that weight trainings such as bench press or squat are closely related to the bone density. However, it still remains unclear how weight training can effect bony structures other than bone density. Newly invented the LD-100 system (Oyo Electronics, Kyoto, Japan), which is a fast, non-invasive ultrasonic instrument, can measure the new indexes of bone other than bone density. Furthermore, to our knowledge, international comparison such as Japan vs. U.S. regarding bony structures has not been conducted. Thus our aim of this study is to compare the Japanese and French population in bony structures based on physical activities, especially focusing on the contact sports athletes who regularly perform weight training as to examine how weight training effects the bone formation. **Methods** As Japanese population data, we collected 2 types of the subjects: (1) the contact sports athletes who are collegiate American football players ($n = 56$, age=20.5±1.2 years), regularly performing weight training, (2) the non-contact sports athletes ($n = 24$, age=20.1±0.5 years), referring to the data collected by Fujisawa et al. (2009). As French population data, we referred to the data collected by Breban et al. (2010), there are 2 types of the subjects: (1) the athletes ($n = 22$, age=24.2 ± 4.3 years), (2) the controls who are non-athletes ($n = 19$, age=27.4± 4.8 years). The data regarding the indexes of bone for the attenuation of waves (dB), radius thickness (mm), cortical thickness (CoTh, mm), and elastic modulus of trabecular bone (EMTb, GPa) were collected by the LD-100 system. All statistical analyses were performed by one-sample t-test. We set the alpha level at .05. **Results** Significant differences ($p < 0.01$) were found in 6 of the 12 comparisons. Of note, the Japanese contact athletes were significantly higher in dB, CoTh, and EMTb than Japanese non-contact sports athletes and French non-athletes. **Discussion** We found that the contact athletes who regularly perform weight training showed superior bony structures. Our results may imply that, besides bone density, weight-training activities can improve the other bony structures. **References** 1) Breban et al. Trabecular and cortical bone separately assessed at radius with a new ultrasound device, in a young adult population with various physical activities. Bone. 2010 Jun;46(6):1620-5 2) Fujisawa et al. ENERGY SYSTEM INTERACTION DURING BASKETBALL EXERCISE SIMULATION IN JUNIOR ELITE PLAYERS

HOOS, O.1, LATZEL, R.1, STIER, S.1, KAUFMANN, S.1, FRESZ, V.1, REIM, D.1, BENEKE, R.2

1: JMU-SS (Wuerzburg, Germany), 2: PUM-ISS (Marburg, Germany)

Introduction The Basketball Exercise Simulation Test (BEST) has been proposed as a novel match-simulating fitness test for elite basketball players showing both discriminative and longitudinal validity (Scanlan et al., 2012). However, the energetic profile of the BEST is not known. Therefore the aim of this study was to assess the energetic profile of the BEST in junior elite basketball players. **Methods** 10 male elite junior basketball players (age: 15.5±0.6y, height: 180±9cm, weight: 66.1±11.2kg) performed a modified BEST (20 circuits on half-court (\approx 1348m) consisting of jumping, sprinting, jogging, shuffling action and short breaks; Scanlan et al., 2012) simulating a 10min quarter of FIBA Europe basketball play. Besides circuit time (C in s), sprint time (S in s) and sprint decrement (SD in %), VO₂ (in ml/kg/min), heart rate (HR in bpm) and blood lactate concentration (blc in mmol/l) were obtained. Metabolic energy and power above rest (Wtot in kJ, Ptot in Watt/kg) as well as energy share (in kJ, %) were calculated from oxygen uptake during exercise (Waer, aerobic component), net lactate production (Wblc, lactic component) and the fast component of post-exercise oxygen uptake kinetics (Wpcr, alactic component) (Beneke et al., 2004). Interrelations between metabolic energy estimates and performance measures were assessed by linear regression. **Results** BEST performances (C: 21.29±1.17s, S: 1.65±0.13s, SD: 11.9±4.2%) elicited peak values of VO₂, HR, BLC of 57.6±3.7ml/kg/min, 202±9bpm, 10.3±2.1mmol/l, respectively. Wtot of 761.0±168.4kJ and Ptot of 19.3±1.6Watt/kg were supplied by a Waer of 673.3±144.1kJ (89±2%), a Wblc of 38.7±13.2kJ (5±1%) and a Wpcr of 49.0±16.5kJ (6±1%), respectively. Assuming an aerobic replenishment of pcr energy stores

during short breaks (8-10s) between circuits (Beneke et al., 2004), the adjusted energy share during BEST yielded Waer: $66\pm4\%$, Wblc: $5\pm1\%$ and Wpcr: $29\pm1\%$. In a stepwise linear regression model Waer explained 54% of variance in S, while Wblc and Wpcr did not further enhance the model. Discussion Consistent with general findings on energy system interaction during maximal exercise (Gastin et al., 2001) our data shows that the intermittent profile of junior elite basketball simulated by BEST primarily relies on aerobic energy. Additionally, a substantial repetitive alactic energy contribution seems to be present. These findings should be considered when basketball specific training programs are designed. THE INFLUENCE OF BACK AND LEG EXTENSOR MUSCLE POWER ON THE SPECIFIC MOTOR SKILLS OF YOUNG WATER POLO PLAYERS

OKICIC, T., DJUROVIC, M., TOSKIC, L., BABOVIC, D.

University of Pristina

The aim of this research was to determine the extent of the influence of the power of back and leg extensor muscles on the specific motor skills of young, school-aged water polo players. The sample of participants in this paper consisted of 20 water polo players ($N=20$), chronological age 12-14, average body weight $85,95\text{kg}$ ($\pm 27,15\text{kg}$), average body height $174,5\text{cm}$ ($\pm 10,25\text{cm}$), seated height $84,25\text{cm}$ ($\pm 7,55\text{cm}$), arm range $183,70\text{cm}$ ($\pm 11,30\text{cm}$), average thorax volume $103,15\text{cm}^3$ ($\pm 15,65\text{cm}^3$), upper arm volume $33,45\text{cm}^3$ ($\pm 6,75\text{cm}^3$), upper leg volume $62,10\text{cm}^3$ ($\pm 10,60\text{cm}^3$) and body mass index $26,02$ ($\pm 7,05$). The anthropometric characteristics were measured using standard anthropometric instruments (GPM, Switzerland). In order to evaluate muscle power, the IMADA 32X-1100 Japanese digital instrument for measuring power, with the software program WinWedge 3.4, was used. In order to evaluate the specific motor abilities, we used a battery of 6 tests (4 tests for the evaluation of swimmer fitness in the horizontal position and 2 two tests for the evaluation of specific motor skills in the vertical position of water polo players). In order to determine the level of muscle power influence we used the canonical correlation analysis and the regression analysis. By using Bartlett's Lambda test we determined that the variables of power and specific motor tests are linked to a single pair of canonical factors at the $p=0,05$ level. The canonical correlational analysis indicated that the greatest influence of muscle power was realized on the variable 30SCBJ (-0,76). The regression analysis showed that there is a mid-intensity correlation between absolute and relative values of back extensor muscle power and the tests of specific motor skills. A partial analysis of the criterion variables indicated that the factors of muscle power realize the greatest statistically significant influence on the 10XCBJ test at the level of $p=0,05$. The results of this study have indicated that the program based on specific extensive high intensity exercise can achieve significantly better results in the development of certain anthropological dimensions, as well as that they are significantly correlated in the sample of young water polo players. The generalization of the results obtained in this study can primarily be applied to the population of young water polo players included in this study.

IMPACT OF PHYSICAL TRAINING PROVIDED IN 12 DIFFERENT SWISS ARMY BASIC MILITARY TRAINING SCHOOLS ON FITNESS DEVELOPMENT OF TRAINEES

BEELER, N.I., ROOS, L.I., HOFSTETTER, M.C., WYSS, T.I.

1: Swiss Federal Institute of Sport Magglingen SFISM

Introduction It is essential to provide recruits with an appropriate physical fitness training (PT) during basic military training (BMT) to boost their fitness level for the successful completion of military tasks and for injury prevention (Wyss et al., 2014). The aim of this study was to investigate the impact of different physical training quantities provided on fitness development in 12 Swiss Army BMT Schools. Methods All recruits of 12 Swiss Army BMT schools were asked to volunteer in this study. Their physical fitness was tested at the beginning and after 10 weeks of BMT using a fitness test battery which consists of five disciplines described in Wyss et al. (2007) and results in a total fitness score (FS) ranging from 0 to 125 points. The PT-instructors registered the duration and content of each PT session in a questionnaire. A linear regression was conducted to quantify the influence of PT quantity, proportion of sports games within PT and initial fitness level on fitness development. Results 1329 recruits from 12 different BMT schools volunteered in this study. The subjects were $20,69\pm0,14$ years old, had a height of $177,57\pm0,87$ cm and a body mass of $73,69\pm1,48$ kg. At the beginning of BMT, an average FS of $74,85\pm4,68$ points was reached, whereas, after 10 weeks, $80,98\pm6,38$ points were achieved. The training schools provided mandatory PT for $124,05\pm40,26$ minutes per week, of which $26,09\pm12,49\%$ was spent on sports games. The linear regression model showed that a low initial FS ($B=-1,033$, $p=0,026$) and a high amount of time spent on PT ($B=0,128$, $p=0,021$) were significant predictors for an increase in FS. Together with the factor "low percentage of sport games" ($B=-0,253$, $p=0,078$) and the intercept of 76,41, these variables describe 68,1% of the variances of the change in FS between BMT schools ($R^2=0,681$, $p=0,022$). Discussion The results indicate that on average, 60 minutes of PT per week are needed to maintain the initial fitness level, whereas 140 minutes are needed for a fitness improvement of 10%. The higher the initial FS, the higher the amount of PT necessary to improve the fitness level. However, not only the quantity, but also the quality of provided PT is crucial. A high percentage of sports games seems to be detrimental to fitness development. Sport games might be more often provided when PT-instructors are lacking time to prepare the PT sessions. It can be concluded that a certain amount of time has to be invested in both the preparation and the execution of PT to ensure recruits are getting physically fitter during their military service. RELATIONSHIP BETWEEN SPECIAL FITNESS TEST SCORE AND ANAEROBIC LOWER LIMB POWER AMONG FEMALE JAPANESE JUDOKAS

OKAWA, M., IDE, Y., OKADA, Y., SAKURAI, T.

International Budo University

Introduction The judo is performed by the Olympic Games and the world championship. The purpose of this study was examined the relationship between Special Judo Fitness Test (SJFT) index and lower limb power in female Japanese judokas. Methods Seventeen female judokas (mean age $20,9\pm0,8$ yrs, mean height $162,9\pm5,6$ cm, and mean body mass $70,3\pm12,9$ kg) performed the SJFT, which comprised three periods (1st =15 seconds, 2nd and 3rd=30 seconds interspersed with 10 seconds rest intervals) test for judo players. During this test, one athlete threw two others positioned 6 m from each other using the ippon-seoi-nage (one arm back carry throw) technique, created and described by Sterkowicz (1995). The following variables were quantified: throws performed during series 1st, 2nd, and 3rd; total number of throws. Anaerobic lower limb power was measured using 30 seconds Wingate Anaerobic Test (WAnT) carried

out by ergometric cycle. Data was analyzed with Pearson's correlation test between the number of throw by SJFT and lower limb power, and used repeated measures ANOVA. Significance level was adopted as $\alpha=.05$ and $\beta=.30$ (effect size $|r|$ is used as the evaluation by Cohen [1988] were used in analyses [Small: .10, Medium: .30, and Large: .50]). Results & Discussion Mean values ($\pm SD$ [lower 95%CI, upper 95%CI]) the number of SJFT throws were 1st: 5.3 ± 0.7 , 2nd: 9.8 ± 0.9 , 3rd: 9.9 ± 0.8 ($p<.001$, generalized eta squared=.885 [$.802, .934$], generalized omega squared=.878 [$.791, .930$], and probability of replication=1.00) [Olejnik and Algina [2003]], and total throws was 24.9 ± 2.2 . The values of mean power and peak power were 436.8 ± 83.3 watts and 567.3 ± 117.4 watts. It was negative correlation between the number of total throw by SJFT and lower limb power (mean power: $r=-.554$ [-.817, -.101], $p=.021$, and power=.67. And peak power: $r=-.496$ [-.789, -.020], $p=.043$, and power=.55). Szmuchrowski (2013) reported no significance correlation between the SJFT and WANt results, which was supported in this study. On the other hand, Franchini et al (2009) who found a correlation between the SJFT and WANt results. It is necessary to consider whether this SJFT is effective for female judo players. EFFECTS OF PLYOMETRIC TRAINING WITH BLOOD FLOW RESTRICTION ON MUSCULOSKELETAL PERFORMANCE AND MUSCLE DAMAGE IN YOUNG ADULTS

PUGGINA, E., TOURINHO FILHO, H., AQUINO, R.L.Q., OLIVEIRA, L.P., MANECHINI, J.P., BERTI JR, J.A., GONÇALVES, L.G.C.

University of São Paulo

Introduction Plyometric training (PT) is efficient to develop high levels of force, as well the use of high training loads. On the other hand, the development of strength through low intensity exercises with blood flow restriction (BFR) have been used in different populations with positive results. However, the BFR method was not investigated in association with PT. In this sense, the aim of this study was to investigate the effects of PT with BFR and without BFR on musculoskeletal performance, anthropometry and muscle damage. Methods 20 men (18-30 years) were divided in two groups; PT-BFR (n= 12) and TP (n= 8) and evaluated before and after a eight week PT protocol. They trained twice a week with BFR (PT-BFR) and without BFR (PT). Musculoskeletal performance was measured using 10m and 30m speed tests, T-40 agility test, horizontal jumps (HJ), vertical jumps (VJ) and the maximum voluntary contraction (1-MVC) in the squat exercise. Percentage of fat, lean mass and lower limbs muscular volume were measured. Muscle damage was assayed by plasmatic activity of creatine kinase (CK) and lactate dehydrogenase (LDH). Results PT-BFR group revealed increases in 30m, T-40, HJ, VJ and 1-MVC tests. PT group improved the 10m, HJ and VJ tests. Despite both groups have shown improvements in the performance tests, the PT group demonstrated significant increases compared with the PT-BFR in the percentage of change of 10m and VJ. There was a correlation between the percentage change of 30m and VJ test in the PT group. It was observed a decrease of fat percentage in both groups. CK and LDH activity were not changed. Discussion Similar data regarding performance observed in this study were found by Cook, Kilduff and Beaven (2014). They found increases in 40m sprint test in the group without BFR and improvements in the CMJ in the BFR group. The increased capacity to produce force after the training, without gains of lean mass may be explained through enhanced activation and synchronization of motor units, firing frequency and co-contraction (CREER et al., 2004). The absence of differences in the CK and LDH activities are probably due to the 72h rest given after the last training bout before the collection. References COOK, C. J.; KILDUFF, L. P.; BEAVEN, C. THE INFLUENCE OF KNEE JOINT ANGLE AND TIME OF FORCE APPLICATION ON VERTICAL JUMP HEIGHT DURING VOLLEYBALL COMMIT-BLOCK

RIVA, G., ROSSI, A., BONFANTI, L., FORMENTI, D., ALBERTI, G.

UNIVERSITÀ DEGLI STUDI DI MILANO STATALE

Introduction Blocking successfully is a crucial feature of winning in volleyball. Key points for the effectiveness of block are anticipation, decision-making, movement speed and jumping ability (Lobietti, 2009). It was found that jumping from a position with knees more flexed seems to be the best strategy to achieve the best performance (Gheller et al., 2015). However, during volleyball commit-block (VCB) the time spent during deeper squat could negatively affect the efficacy of the VCB (Ficklin et al., 2014). Thus, we aimed to investigate the influence of three different knee starting angles and the time of force application on jumping performance during VCB. Methods Fifteen volleyball players were recruited (20.27 ± 3.08 yrs, 76.60 ± 9.27 kg, 184.53 ± 6.63 cm). Players performed three maximal vertical jumps in commit position in front of the volleyball net. In the first one the players performed jumps using their optimal knee joint angle (OR) (105.91 ± 14.80 deg). The second one was performed over their optimal one (OOR) (71.13 ± 18.13 deg) and third one under the optimal one (UOR) (135.94 ± 7.95 deg). The vertical jump height (VJH) and the time of force application (TFA) were obtained by Optojump Next (Microgate, Italy). The knee joint angle (KJA) was assessed using Microsoft Kinect™. One-way MANOVA corrected by GreenHouse-Geisser adjustment was used to detect differences among jumps in VJH, TFA, and KJA. The magnitude of the difference was assessed by partial eta squared (part η^2). LSD was performed in accordance to univariate ANOVA. Results The MANOVA showed statistical difference among the three jumps ($F(6,9)=53.273$, $p<0.001$, part $\eta^2=0.973$). The univariate test detected difference among the independent variable in each dependent variable (VJH: $F(1.93,27)=30.601$, $p<0.001$, part $\eta^2=0.686$; TFA: $F(1.96,27.49)=112.196$, $p<0.001$, part $\eta^2=0.889$; KJA: $F(1.807,25.303)=114.864$, $p<0.001$, part $\eta^2=0.891$). In VJH, difference between OR and UOR ($p<0.001$) was detected by LSD but no statistical difference was found between OR and OOR ($p=0.956$). In TFA and KJA, statistical differences were found by LSD in each pairwise comparisons ($p<0.001$). Discussion In contrast to Gheller et al. (2015), no difference was found in VJH, even if both TFA and KJA were different between OR and OOR. Thus, jumping at the preferred range should be the best way to reach successful VCB because of higher vertical jump performance applying shorter TFA than OOR. AORTIC ROOT DIMENSION IN SOCCER PLAYERS

OLM, T.1, BASKIN, K.2, HERDE, K.2

Tallinn University

Introduction Cardiac adaption to different sports has been extensively described. However the potential effect of top-level training on the aortic root dimension (AO) remains less investigated. At same time the frequency of cases of pathological dilatation of AO in top-athletes has been increasing. The aim of this study is to assess echocardiographic characteristics in order to elucidate aortic adaption in different age groups of soccer players. **Methods** The subjects were 247 soccer players of the best clubs of Estonia. In the first group (n=149) the average age was 19.1 ± 1.24 and in the second group (n=98) 25.3 ± 3.12 years. The test battery included anthropometrics, ECG, and treadmill test and BLa concentration, VO_{2max}, anaerobic threshold were recorded. The echocardiography was performed using GE Vivid E/9. The t-test and Pearson product moment correlation coefficients were calculated. **Results** Means: Group 1 (n=149): Age (y) 19.1 ± 1.24 ; BSA (m²) 1.95 ± 0.12 ; AO (mm) 29.2 ± 2.30 ; AO/BSA (mm/m²) 15.0 ± 1.34 . Group 2 (n=98): Age (y) 25.3 ± 3.12 ; BSA (m²) 1.99 ± 0.11 ; AO (mm) 31.0 ± 2.18 ; AO/BSA (mm/m²) 15.6 ± 1.13 . **Discussion** Sport-specific adaptive cardiac structural changes are still under debate. D'Andrea et al. (2010) concluded that the AO diameter was significantly greater in strength-trained athletes (n=245) than in endurance athletes (n=370). At the same time Pelliccia et al. (2010) assessed athletes of 28 different sports disciplines (n=1300) and showed that the AO dimension was explained by weight, height, left ventricular mass (LVM) and age, with type of sports training having a significant but lower impact. The mean AO was greater (32.2 ± 2.7 mm) than in our soccer players and 1.3% of athletes had an enlarged AO (over 40 mm). In our investigation the greatest AO is 37 mm in both age groups. Correlation analysis shows that statistically significant correlations between AO and other indices are similar in both groups. AO has the strongest correlation with LVM, moderate relationship with left atrial dimension and significant but surprisingly low correlation with age. **Conclusion** We can conclude that in soccer players sports-specific influence on the aortic root dimension occurs early and progresses moderately, being part of the symmetric remodeling of heart. **References** D'Andrea A I, Cocchia R, Riegler L, Scarafilo R, Salerno G, Gravino R, Vriz O, Citro R, Limongelli G, Di Salvo G, Cuomo S, Caso P, Russo MG, Calabro R, Bossone E. RELATIONSHIP BETWEEN PHYSICAL CHARACTERISTICS AND PERFORMANCE LEVEL OF COLLEGE KENDO ATHLETES.

HIRONO, J.1, KANDA, T.2, HAYAMI, T.1, ARITA, Y.3, NABEYAMA, T.3, KODA, K.3

1: Shinshu University (Nagano, Japan), 2: Chubu University (Aichi, Japan), University of Tsukuba (Ibaraki, Japan)

Introduction Kendo is the Japanese martial arts originating from Samurai traditions. During the course of the game, Kendo athletes were required to respond to various situations, to move quickly in various directions. Thus, high performance Kendo athletes had great physical fitness level. However, few previous studies report physical characteristics and performance level of Kendo athletes. The purpose of this study was to evaluate relationship between physical characteristics and performance level of college Kendo athletes. **Methods** Twenty-four male Kendo athletes were participated in the experiment. Eight subjects had expert group (EG); they were regular players on the same university Kendo club, what club has won the annual team competition for all Japanese universities many times. Eight subjects had intermediate group (IG); they were regular players on the other university Kendo club, they were no participation experienced of the annual team competition for all Japanese universities. Eight subjects had under-skilled group (UG); they were not regular players on the same team as IG. Experiment was conducted in accordance with the Declaration of Helsinki. 30-m sprints, vertical jump (VJ), forward medicine ball throw (F-MBT), backward medicine ball throw (B-MBT), repetitive side step (SSI), multistage 20-m shuttle run test (20mSR) were measured. For the statistical analysis, One-way ANOVA by means of comparison between groups. The statistical significance was set at $p < 0.05$ for all analyses. **Results** All Results show that UG had poorest in all groups. Significant correlations were found between IG and UG during VJ and B-MBT ($p < 0.05$). In the B-MBT, IG showed significant differences against EG ($p < 0.05$; IG > EG). Other physical characteristics measurements showed no significant differences. **Discussion** In this study, UG showed poorest physical fitness level. From the result, it is necessary to some extent physical fitness level that Kendo athletes make high performance. However, they were almost no significant differences almost measurements between EG and IG. Furthermore, In the B-MBT, IG showed excellent result against EG. Therefore, in the university Kendo athletes who are higher than a constant level, it is thought that it is important how you make use of each physical property in a competition than the improvement of the physical level. COMPARISON BETWEEN DIFFERENT MEASUREMENTS OF PROPRIOCEPTION FOLLOWING ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE

LIN, M.1, LIN, J.1, CHEN, H.1, CHEN, T.2

1:NCYU (Chiayi, Taiwan), 2:NTNU (Taipei, Taiwan)

Introduction There has well-documented shows eccentric exercise of the agonist will occur obvious exercise-induced muscle damage (EIMD) and delayed onset muscle soreness (DOMS). There are several indicators to asses muscle damage including circumference (CIR), muscle soreness (SOR), range of motion (ROM), maximal isometric voluntary contraction strength (MVIC) and plasma creatine kinase activity (CK). The previous studies [1,2] reported EIMD will impact position sense (PS) and reaction angle (RA) of lower limb function. However, there did not have research about comparison between different measurements of proprioception in EIMD. This study investigated the effects of different measurements of PS and RA knee flexors after EIMD. **Methods** Eight untrained young men performed an eccentric exercise of the knee flexors by the non-dominant leg to induce muscle damage. To observe the changing of CIR, SOR, ROM, MVIC, PS and RA at measured before, immediately after, 1~5 days after exercise. The assessments of PS and RA included concentric contraction (CC) and eccentric contraction (EC). Data were compared by repeated-measures of two-way ANOVA and Pearson product-moment correlation coefficient. **Results** All variables changed significantly following eccentric exercise ($p < .05$). After eccentric exercise, the variety of EC was greater than CC ($p < .05$). **Discussion** These results showed that eccentric exercise not only occur muscle damage, but also affect the proprioceptive assessment methods measured [3]. There has high correlation between using EC means measurement after eccentric exercise and other muscle damage indicators. Therefore, the best way for testing proprioception might be EC measurement after eccentric exercise. **References** 1) Paschalis et al. (2008). Eur J Appl Physiol, 103, 9-18. 2) Paschalis et al. THE ACUTE EFFECTS OF DYNAMIC WARMUP ON SINGLE LEG BALANCE TEST IN SCHOOL CHILDREN

NG, S.K., HO, S.C., NG, C.K.

The Chinese University of Hong Kong

Introduction Balance is one of the components of physical literacy. The immediate effects of two different kinds of dynamic stretching on static balance in school children have not been investigated. Therefore, the aims of this study were to 1) determine if two different kinds of dynamic warmup were associated with performance of open eyes and closed eyes single leg balance tests in school children; 2) explore any response differences between boys and girls on balance performance after performing the two dynamic warmups. Methods This study employed a randomized, crossover with repeated measures design. After a static warmup protocol and familiarization session, 61 school children (age: 10.5 ± 0.8 years; height: 1.35 ± 0.06 m; weight: 31.5 ± 6.2 kg; BMI: 17.1 ± 2.3 kg/m²) performed two baseline measurements, namely single leg balance test with open eyes (T1) and with closed eyes (T2) in random order with their dominant leg on the floor. Warmup protocol: Warmup A (WA) - Four points formed a square with 30cm length. Children started at left bottom corner and hopped with their dominant leg with 1-sec pace between each point six cycles clockwise. Warmup B (WB) - Their dominant leg stepped on the floor, the other leg stretched out to 3 points located 30cm from the dominant leg at the sequence of anterior, posteromedial and posterolateral directions eight times with 1-sec pace between each point. Procedure: Each child performed one warmup (WA/WB) and two tests (T1 and T2). After 2 min rest, they performed the other warmup and the two tests. The warmups and tests order were randomly assigned. Results Results of Multivariate tests showed that there was no statistically significant differences in two main effects (WA & WB), gender and no interaction was observed $F(4, 352) = 0.482$, $p = 0.749$; Wilk's $\Lambda = 0.989$, partial $\eta^2 = 0.005$. Results of one-way ANOVA showed that there was no statistically significant differences among baseline, WA and WB in T1 ($F(2, 180) = 0.472$, $p = .624$) and in T2 ($F(2, 180) = 0.160$, $p = .852$). The girls obtained the mean values of T1 increased 1.7 sec or 0.04% after WA and increased 6.0 sec or 14.5% after WB, whereas the boys obtained the average values of T1 decreased 0.6 sec or 1.45% after WA and increased 0.9 sec or 3.2% after WB. No improvement in T2 was observed in girls after performing WA and WB, while the average values of T2 increased 2.3 sec or 17.8% after WA and increased 2.2 sec or 17.1% after WB. Discussion These findings suggested that the use of WB improved the performance of T1 in girls, while the employment of WA improved the performance of T2 in boys. Our findings were limited to school children of age group from 9 to 11 years old. The underneath mechanism is not clear. Some children reported tiredness of their dominant legs at the end of the tests. Contact saroerbt1218@gmail.com o not insert authors here

EARLY CARDIAC REHABILITATION EXERCISE TRAINING IN OLD PATIENTS AFTER HEART SURGERY - TRAINING OR ACTIVATING EFFECTS?

EDER, B.I., HOEDL, R.I., HOFMANN, P.2

1: Center for Cardiac Rehabilitation St. Radegund (Austria)/2: University of Graz (Austria)

Introduction Early recovery of functional capacity after heart surgery is important for a successful reintegration in daily living. Aim of the study was to prove the effects of a standard rehabilitation program on exercise performance after heart surgery in older patients (Eder et al. 2010). We hypothesized that these patients would rather show activating than true training effects after 4 weeks of early rehabilitation. Methods The study included 60 (32 male, 28 female) patients (mean age 73.1 ± 4.7 12.2±4.9 days after heart surgery. Subjects were trained in a standard rehabilitation training program individually adjusted for exercise performance and disease severity. All subjects performed a symptom limited ergospirometry. The MacNew questionnaire was used to assess quality of life (QOL). All tests were performed before and after four weeks of cardiac rehabilitation. Patients underwent structured and regulated walking or cycle ergometer exercise training. LTP1 and LTP2 as well as VT1 and VT2 were determined from lactate and gas exchange data according to usual standards (Kroidl et al. 2015). Results Subjects increased their VO₂peak from PRE (0.93 ± 0.21 ml.kg⁻¹.min⁻¹) to POST (1.21 ± 0.14 ml.min⁻¹.kg⁻¹) by 30.1%, with an increase in HRmax from PRE (102 ± 28 min⁻¹) to POST (117 ± 26 min⁻¹). Also maximal power output (P) significantly increased from PRE (44 ± 14 W) to POST (69 ± 16 W) by 55.7%. VO₂ as well as P at LTP1 and LTP2 significantly increased from PRE (VO₂: 0.62 ± 0.11 / 0.84 ± 0.16 ml.kg⁻¹.min⁻¹; P: 14 ± 7 / 36 ± 10 W) to POST (VO₂: 0.74 ± 0.18 / 1.01 ± 0.21 ml.kg⁻¹.min⁻¹; P: 25 ± 10 / 51 ± 13 W), however this increase of 24.9 / 33.9% (P) and 12.9 / 18.3% (VO₂) was significantly smaller compared to maximal. QOL scores significantly improved by 17.5%. Discussion The cardiac rehabilitation program significantly improved both maximal and sub-maximal exercise performance and QOL in old patients after heart surgery although the effects of activation indicated by an increase in HRmax were substantially greater than thresholds increases. We conclude that improvements in maximal exercise performance in patients after a training program should be interpreted with care as these improvements may just show a re-activation, a higher motivation or less fear not accompanied by true sub-maximal training effects which are more relevant for daily activities of the patients. The determination of turn points is recommended. References Eder B, Hofmann P, von Duvillard SP, Brandt D, Schmid JP, Pokan R, Wonisch M.: J Cardiopulm Rehabil Prev. 2010 Mar-Apr;30(2):85-92. THE EFFECT OF DIFFERENT REST INTERVALS BETWEEN SETS ON THE REPETITION MAXIMUM, EXERCISE VOLUME, AND PHYSIOLOGICAL RESPONSES DURING 10 RM BARBELL CURLS

KIM, K.H.1, HAN, K.M.2, YANG, C.H.3

1: Dankook University/Korea, South), 2: San Jose State University/USA, 3:Hanseo University/Korea, South)

Introduction Weight training for the Pectoralis consists of bench press and pectoral fly, shoulder exercises are barbell presses and dumbbell lateral, brachial triceps exercises are triceps press downs and dumbbell kickbacks. For the bottom, squatting is the best exercise, while for biceps; the barbell curl is the best exercise (Hass, et. al., 2001). In this study, a single joint exercise, the barbell bicep curl was performed while measuring the heart rate and blood pressure. Measurements were also taken with changes in the number of iterations between the total momentums of the set along with the resting period. Conditions measured were the systolic blood pressure, and heart burden, analyzed on the basis of (RPP, myocardial oxygen demand). The purpose of the study was to identify the influence to change of repetition maximum, total work, HR, SBP, and RPP by different rest interval with in sets during 10RM Barbell Curls. Methods Weight training career more than twelve months and not more than health medical test results to target 10 men resting 30 seconds between sets, 90 seconds 180 seconds, respectively, under the conditions 5 set 10 RM Barbell Curls exercises were performed for each set of repeated count, the total work, HR, SBP, RPP was measured. Results 10 RM Barbell Curls exercise sets 5 sets the number of repetitions and the total work progressed significantly decreased, in accordance with the rest interval time of 180 seconds, 90 seconds, 30 seconds rest in order. Heart rate in a 30-second condition was significantly decreased after 4 sets, 90 seconds and 180 seconds condi-

tions tended to be maintained. Conditions, the systolic blood pressure increased significantly and 90 seconds, 30 seconds conditions showed a decreasing pattern, 180 seconds did not show significant changes in conditions. Conditions, the RPP compared to 30 seconds 90 seconds 180 seconds and showed a tendency in conditions, or there was no significant difference. Discussion In this study in case of the 10RM barbell curl exercise, 180 seconds was the most idealistic resting rate dependant on the heart rate, repetition, and the total amount of exercise. 90 second resting time had an increase in blood pressure and a 30 second resting period was too short for maximum muscle use. If the repetition of 1 set is 100%, than when the set reaches 50%, heart rates increase and it is more difficult on the heart to maintain the exercise. The rest time between the sets is dependant on the heart rate, repetition, and the total amount of exercise(Fleck, 2003). For the increase in muscle development for 10RM barbell exercises, the ideal resting time is 90 seconds to 180 seconds. References Fleck, S. J. (2003). Cardiovascular responses to strength training. EFFECTS OF FUNCTIONAL PANTS WEARING ON AEROBIC AND ANAEROBIC MOTOR ABILITY, LACTATE, AND MUSCLE PAIN IN COLLEGE STUDENTS

KO, S.S.1, HAN, K.M.2, KIM, K.H.3, CHO, M.H.3, KIM, A.R.3, KIM, B.K.3, KIM, D.O.3, JEONG, H.J.3

1:Korea National University of Transportation(Korea, South), 2: San Jose State University(USA), 3:Dankook University(Korea, South).

Introduction The purpose of this study was to prove the effects of functional pants wearing on aerobic and anaerobic motor ability, fatigue, and muscle pain in college student's. Methods Eight healthy college men participated in this study and subjects had not been involved in a resistance-training program at least 6 months. All subjects (n=8) performed two bouts of maximum exercise load test and wingate test in wearing and non-wearing of functional pants separated by 2 and 3 weeks. Aerobic and anaerobic motor ability, lactate in the blood and muscle pain were taken before, immediately after, 3, and 10 minutes in each wearing and non-wearing of functional pants. Results Our study showed that exercise time, VO₂max and reaching time to maximum power had positive effects following the wearing of functional pants compared to the non-wearing of functional pants. After aerobic exercise, muscle pain was significantly lower following the wearing of functional pants compared to the non-wearing of functional pants, and lactate recovery rate in the blood was significantly faster following the wearing of functional pants compared to the non-wearing of functional pants. Discussion These data indicated that the wearing of functional pant improve aerobic motor ability and muscle pain(Chng et al., 2010; Davis & Green, 2009; Inbar & Bar-Or, 1986; Tariq et al., 2005). EFFECTS OF SPECIAL MUSCLE STRETCHING ON THE BALL-SPEED AT DRIVER SWING OF AMATEUR GOLF PLAYERS

KIM, J.M., YOON, S.D., SEONG, D.H., PARK, G.D., KIM, S.J.

Keimyung College University

[Purpose] In the present study, therefore, stretching exercises were performed by the subjects in order to examine their effects on golf swing-related factors that can be easily influenced by continuous and long-term repetitive movements, unstable postures, and excessive force. The study goal was to examine the effectiveness of stretching exercises for improved swing. The study investigated stretching for a safer golf swing compared to present stretching methods for a proper swing in order to examine the effects of stretching exercises on golf swings. [Subjects] The subjects were 20 amateur golf club members who were divided into two groups: an experimental group which performed stretching, and a control group which did not. The subjects had no bone deformity, muscle weakness, muscle soreness, or neurological problems. [Methods] A swing analyzer were used as the measuring tools. The swing analyzer was a GS400-golf hit ball analyzer (Korea). [Results] Hit-ball speed at golf driver swings were measured and the results show there was an increase of approximately 5m/s from 67.30±5.40m/s before the intervention to 72.00±4.73m/s at 12 weeks in the experimental group, but there was little change from 66.30±4.78m/s before the intervention to 67.90±4.81m/s at 12 weeks (Table 3)in the control group. Two-way repeated ANOVA the results show there were no interaction effects but there were significant differences ($p<0.05$) between the groups ($F=5.95$, $p<0.05$). [Conclusion] To examine the effects of a special stretching program for golf on golf swing-related factors, 20 male amateur golf club members performed a 12-week stretching training program.

EFFECTS OF PROPRIOCEPTIVE REHABILITATION TRAINING ON MUSCLE FUNCTION IN PATIENTS WITH KNEE OSTEOARTHRITIS

SEONG, D.H., YOON, S.D., KIM, S.J., PARK, G.D., KIM, S.D.

Keimyung College University

[Purpose] This study applied proprioceptive circuit exercise to patients with degenerative knee osteoarthritis and examined its effects on knee joint muscle function and the level of pain. [Subjects] This study included 14 female patients, ≥60-years-old, who demonstrated both clinical and radiological evidence of knee osteoarthritis, as described by the American Rheumatism Association, a proprioceptive circuit exercise group (n = 7) and control group (n = 7), were examined. [Methods] The proprioceptive circuit exercise program (20min/session) lasted for eight weeks. The subjects participated in the exercise program three times a week. Three sets (10 times/set) per session of the proprioceptive circuit exercise was performed. The detailed exercise program was consisted of the repetition of walk-in-place and four different types of proprioceptive circuit exercise including half squat, straight lunge, side lunge, one-legged balance exercise on a Jumper (TOGU, Germany) and Aero step (TOGU, Germany). For those participants who were unable to perform exercise properly due to the loss of their balance from the equipment, an exercise instructor held participants' hands until the end of each exercise. ISOMED 2000 (Germany) was used to measure knee joint isokinetic strength. [Results] In the proprioceptive circuit exercise group, knee joint muscle function whereas in the control group, no significant improvement was observed. [Conclusion] A proprioceptive circuit exercise may be an effective way to strengthen knee joint muscle function in patients with knee osteoarthritis.

EFFECT OF WATER TEMPERATURE AQUATIC EXERCISE ON CARDIOVASCULAR SYSTEM AND BLOOD LACTATE CONCENTRATION**

KIM, K.H.1, KIM, J.H.1, LEE, D.H.1, KIM, B.K.1, KO, S.S.2, CHOI, J.I.3

1: Dankook University, 2: Korea National University of Transportation, 3: Hanseo University.

Introduction The purpose of this study was to investigate the effects of aqua exercise with different water temperatures on heart rate, body temperature, cardiovascular stress and blood lactate among male college students of physical education major. **Methods** For this study 8 subjects were recruited and experienced aqua exercise and rest period with 18°C and 38°C water temperature, and physiological variables were measured at rest and 5, 10, 15 and 20 minutes post exercise. **Results** 1) heart rate response at rest to 38°C condition was found to be greater than that of 18°C water temperature($p<.001$). heart rate response during exercise is higher at 38°C than that of 18°C ($p<.001$). heart rate response to different measurement times were significant($p<.001$) 2) systolic blood pressure at rest was greater at 18°C than that of 38°C($p=.001$). systolic blood pressure during exercise was found to be greater at 18°C than that of 38°C ($p=.001$). Systolic blood pressure at different measurement times was also significantly different ($p<.001$). 3) resting cardiovascular stress was not significantly different between 18°C and 38°C temperature condition. cardiovascular response to exercise was not different between 18°C and 38°C condition. But, cardiovascular stress at different measurement times was statistically different ($p<.001$). 4) changes in body temperature at resting condition was found to be higher at 38°C than that of 18°C ($p=.001$). changes in body temperature during exercise was higher at 38°C condition than 18°C ($p=.001$), and therefore this change in body temperature based on measurement times was statistically different($p<.001$). 5) blood lactate at rest showed greater response at 18°C condition than 38°C ($p=.01$). blood lactate response during exercise was greater at 38°C than 18°C($p=.001$). Blood lactate response at different time ranges was also statistically different ($p<.001$). **Discussion** Taken together, heart rate response at 38°C water temperature at rest and during exercise was found to be greater, systolic blood pressure at 18°C water temperature was shown to be greater at rest and during exercise. There was no difference at rest and during exercise in terms of cardiovascular stress. Changes in body temperature at rest and during exercise was greater on 38°C water temperature. Blood lactate response at 18°C water temperature was greater than the other water condition. Therefore, heart rate response at 38°C water temperature was found to be greater at rest and during exercise, and systolic blood pressure was found not to be different at any water temperature. Blood lactate response at resting 18°C water temperature was found to be greater and was found to be greater at 38°C water temperature during exercise. These results means that recovery process is recommended on warm water. * para@hanseo.ac.kr **This study was conducted to establish the foundation of Wellness Spa Clinical Coordinating Center(N0001200), and supported by "Ministry of Trade, Industry and Energy" and "Korea Institute for Advancement of Technology"

RESEARCH REGARDING PHYSICAL FITNESS CHARACTERISTICS VIEWED OVER A LONG PERIOD OF TIME TARGETING JUNIOR TENNIS PLAYERS

UMEBAYASHI, K.1, IMANISHI, T.2, SUDA, K.3

1: Osaka University Health and Sports Sciences (Osaka, Japan), 2: Rikkyo University (Tokyo, Japan), 3: Tokyo Institute of Technology (Tokyo, Japan)

Introduction It has been a long time since the physical fitness improvement plan intending to strengthen Japan's tennis players started. We have been implementing physical fitness measurement of junior players in the Japanese tennis player training project since 2001. The purpose of this research is to analyze the results of physical fitness measurements of junior tennis players which we implemented from 2001 to 2012, understand the characteristics thereof, and suggest a directionality for future physical training. **Methods** The junior tennis players who were the subjects of measurement were 139 players from age 12 to 16 who had achieved good results in domestic and overseas matches and been designated in each region as strengthened. The items measured were height, weight, grip strength, standing long jump, sit-ups, long sitting body anteflexion, round-trip running, 5-direction run, shuttle stamina, and medicine ball throwing. The method of analysis was aggregating the physical fitness measurement results by gender and comparing them by year (2001 group, 2005 group, and 2012 group). Furthermore, we converted the measurement data to a standard score (H score) and conducted a comparison on relative physical fitness points to consider the characteristics of each year. **Results and Discussion** The comprehensive physical fitness points were significantly lower in the 2012 group compared to the 2001 and 2005 groups in both boys and girls. Among these, the most remarkable differences were found in sit-ups, grip strength, and medicine ball throwing-items which require muscle strength. On the other hand, in the girls the tests of physique, endurance running (shuttle stamina), sprinting ability (running back and forth on the court) tended to be better in the 2012 group. No difference was observed in sprinting ability among the boys. These facts suggest the possibility that recent Japanese junior tennis players have adopted a playing style which focuses on sprinting ability and footwork and training focusing on these as well in comparison to past junior tennis players. The results suggest that in the future it will be necessary to maintain this play style as a foundation while making training plans which emphasize muscle strength and power-related physical fitness building.

PEAK TORQUES AND HAMSTRING TO QUADRICEPS RATIO IN PROFESSIONAL SOCCER, FUTSAL AND BASKETBALL PLAYERS

PARPA, K., MICHAELIDES, M.

Uclan University of Cyprus

Introduction Quadriceps (Q) and hamstrings (H) muscle strength inadequacies and imbalances has been shown to be associated with increased risk of lower extremity injury in athletes. A reduced (0.75 or less) hamstring to quadriceps ratio (H/Q ratio) may put athletes at a higher risk for lower extremity injuries. The purpose of the present study was to examine the peak torques of the Q and H muscles and their torque-ratio (H/Q) in professional soccer, futsal and basketball players. In addition, differences between the limbs were examined. **Methods** Seventy six participants (football n: 44, futsal n: 16, basketball n: 16) were evaluated using an isokinetic dynamometer. Peak torque and H/Q ratios were evaluated at both 60 degrees/s and 300 degrees/s. **Results** It was found that basketball players produced significantly greater torques (at 300degree/s) in both the right and left Q compared with the football and futsal players [$F = 7.37$, $p<0.05$ and $F = 7.25$, $p<0.05$ for right and left Q respectively]. In addition basketball players demonstrated significantly greater torques for hamstrings compared to the other 2 groups [$F = 5.98$, $p<0.05$ and $F = 5.55$, $p<0.05$ for right and left H respectively]. No significant differences were observed in H or Q torques or H/Q ratio among the players of different sports. Finally, no significant differences were observed between the right and left limbs among the players with mean values being less than 10% in all groups. **Discussion** It is concluded that basketball players have stronger quadriceps and hamstring muscles only when tested at faster speeds. Also, based on the H/Q ratios

and the absence of asymmetries these professional players do not seem to be at an increased risk for injuries. Isokinetic evaluation of the lower extremities may provide the coaching team with valuable evidence regarding potential asymmetries between Q and H that may progressively contribute in performance deterioration and increase the risk of muscle injuries development. Possible asymmetries may be eliminated by incorporating the appropriate training into the habitual exercise routines of professional athletes.

CONSCRIPTS PHYSICAL ABILITY LEVEL AND THEIR OUT DURING BASIC TRAINING COURSE IN 2011 -2014

STAMM, M., ANTON, H.

Estonian Defence Forces

Introduction Several studies in the field of military confirmed that low physical capability of conscripts may affect their military training and obligations (Tomczak et al., 2012). More recent studies have confirmed that a low physical performance is one important reason for the dropout before the end of recruit basic training courses (BTC), due to health problems or injuries (Taanila et al., 2011). The purpose of this study was to analyze conscripts physical ability level and dropout during their Basic Training Course (BTC) in 2011 – 2014. **Methods** The sample of this study consists of conscripts who began service in 2011 (n=3352), in 2012 (n=3235), in 2013 (n=3255) and in 2014 (n=3264). To assess soldiers physical condition and their progress of training suitability we use in Estonian Defense Forces (EDF) the United States Army Physical Fitness Test (PFT) which is modified for the EDF demands. PFT is designed to test the muscular strength, endurance, and cardiovascular respiratory fitness of soldiers (Army Physical Readiness Training 2012). The test consists three different exercises: (1) push-ups in two minutes; (2) sit-ups in two minutes and (3) 3.2 kilometers run. Scoring of the PFT is based on gender, age category and number of repetitions performed, where each event ranges from 0 to 100 points. To pass the PFT is necessary to collect more than 190 points as the sum of three exercises. All soldiers in EDF must do the PFT; first test at the start of the BTC, second at the end of the BTC and third at the end of the service time. In this study we focus on first two tests. **Results** The PFT analysis revealed that the first test successfully passed 38,6 – 50,8% of conscripts and second test 87,4 – 95,2% of conscripts in different years. There were not statistically significant differences between passing the tests in different years. The dropout during the BTC was 3,7 – 5,5% of conscripts in different years. If we compared conscripts first test and their dropout during the BTC, we found that as higher was the first test passed recruits number that lower was the dropout conscripts number. **Discussion** In conclusion we can say that the physical preparation of the conscripts is very different before military service. It is important to raise the recruits physical ability before the military service to make their BTC more effective. **References** Army Physical Readiness Training. (2012) FM 7-22, HQ, Department of the Army, Washington, DC, USA. Taanila H., Hemminki A.J.M., Suni J.H., Pihlajamäki H., Parkkari J. (2011). Low physical fitness is a strong predictor of health problems among young men: a follow-up study of 1411 male conscripts. BMC Public Health, 2011 11: 590. Tomczak, A., Bertrandt, J., Kłos, A. (2012). TAI CHI CHUAN TRAINING MAY IMPROVE BALLET MOVEMENTS IN SENIOR HIGH SCHOOL STUDENTS

TSAI, Y.S., YU, H.B., CHANG, Y.H., LIAO, P.Y.

University of Taipei

Introduction Tai Chi Chuan (TCC) training is known to be able to improve core stability and balance while performing various movement tasks. Whether TCC training can contribute to the performance of jumps, spin, and balance required in ballet dancing is unclear. The purpose of this study was to investigate the effect of 8-week TCC training on the ballet movements (sauté jumps, pirouette en dehors spin, and passé posture balance) of senior high school dance class students. **Methods** A total of 16 senior high school dance class students participated in this study (8 in the training group and 8 in the control group). The two groups had similar age, body height, body mass, and around 10 years of dancing experience. The training group received Yang Style (24 form) TCC training for 8 weeks (2 times/week, 1.5 hours/time) in addition to their regular dance class. The control group had the same regular dance class as the training group without receiving additional training. An AMTI force platform (1,000Hz) was used to measure the sauté jump explosive force and air hang time and passé posture balance of the participants. A motion analysis system with 9 infrared high speed cameras (200Hz) was used to record their lower extremity movements when performing pirouette en dehors. Independent t tests were used to compare the differences in the percentage of changes of all variables after 8-week training period between the two groups. **Results** The results showed that the training group demonstrated greater improvement than did the control group in the following areas: the maximum lower extremity push-off force ($4.63 \pm 2.86\%$ vs. $-1.84 \pm 2.87\%$, $p<0.001$) and air hang time ($5.18 \pm 2.65\%$ vs. $-7.03 \pm 4.76\%$, $p<0.001$) during sauté jumps; the front-back ($-11.70 \pm 10.18\%$ vs. $-0.46 \pm 9.63\%$, $p=0.04$) and right-left ($-14.53 \pm 10.30\%$ vs. $1.27 \pm 10.02\%$, $p=0.008$) center of gravity (COG) shift distance during passé posture balance; and the working leg hip joint external rotation angle ($6.38 \pm 4.79\%$ vs. $-1.47 \pm 2.62\%$, $p=0.001$), the supporting leg plantar flexion angle ($2.76 \pm 1.14\%$ vs. $-3.20 \pm 3.98\%$, $p=0.001$), and the front-back ($-24.39 \pm 14.54\%$ vs. $17.03 \pm 44.07\%$, $p=0.024$), right-left ($-31.77 \pm 15.35\%$ vs. $29.59 \pm 55.04\%$, $p=0.009$) COG shift distance during pirouette en dehors spin. **Discussion** Tai Chi Chuan training seems to be able to improve some of the ballet movements that may contribute to the performance of young dancers. A plausible reason may be due to TCC training improved their trunk and lower extremity control ability that allowed them to perform ballet movements more proficiently. All participants in this study were in the same class. The limitation of the study is that the control group was not able to have the same amount of training time as the training group had due to various reasons. Contact yungshentsai@gmail.com

EFFECTS OF MENTAL AND PHYSICAL FATIGUES ON FOOTBALL PLAYERS' IN-GAME BEHAVIOURS

COUTINHO, D., GONÇALVES, B., WONG, D.P., TRAVASSOS, B., SAMPAIO, J.

University of Trás-os-Montes e Alto Douro, and Shandong Sport University

This study aimed to identify the effects of mental and peripheral physical induced fatigues on football players' in-game behaviours. Ten Under-15 players performed a Gk+5v5+Gk small-sided game (SSG) on a 30x20m pitch based 3 bouts of 6 minutes each, and performed under three different conditions: i) physical fatigue condition (PF), induced by performing a repeated change-of-direction; ii) control condition (CTR), in which players performed the SSG without any previous activity; iii) mental fatigue condition (MF) using a 30 minutes computerized version of the Stroop task. Time-motion variables and players' positional data were gathered using global positioning systems (5 Hz). Positional data were used to compute tactical-related variables such as team's stretch index, distance between players' dyads and synchronization of longitudinal and lateral displacements of players' dyads. When compared with CTR condition, players under PF condition was likely to lower the number high-intensity accelerations by ~33% (Cohen's d: 0.5 ± 0.5) and possibly lower the ratio of high distance covered by ~38% (Cohen's d: 0.3 ± 0.5). From the tactical perspective, the distance between players' dyads in PF was very likely

lower compared to CTR. Also in PF, player's spent likely ~7% more time synchronized in longitudinal displacements than in CTR and most likely ~14% more than in MF (Cohen's d: 0.7 ± 0.3). The teams' stretch index were very likely and most likely lower in MF than in PF and CTR, respectively. Although players spent less time synchronized in MF, the distance between players' dyads showed a very likely more predictable pattern (i.e., lower approximate entropy values) in MF than in PF (Cohen's d: -0.4 ± 0.2) and possible more than CTR. Applying a physical stimulus previously to tactical tasks may be used to promote an increase in players' longitudinal displacements synchronization and optimise the in-game physical performance, since dyads become more coupled. The induced mental fatigue decreased the team dispersion and the time that players' spent synchronized in longitudinal displacements. This self-organized behaviour may be linked with the increased perception of mental fatigue, that encouraged team contraction and as consequence of higher proximity between players might decreased the need to stay synchronized with the surrounding teammates. Therefore, induced mental fatigue seems to change the way of how players perceive the environmental information. Overall, coaches may use both situations to promote variability in players' tactical behaviours, and consequently, provide wide adaptive environments.

PRE SEASON VO₂MAX ESTIMATION OF YOUNG MALE ELITE BASKETBALL PLAYERS

SEMPF, F., BRAHMS, C.M., THIENES, G.

Georg-August-University Göttingen

Introduction Aerobic capacity is an important determinant of team sport performance that can accurately be assessed with spirometry. Due to the complex set up and high costs, there is a need to establish quick and feasible alternatives. One popular field test is the shuttle run, which has repeatedly been shown to yield accurate and valid VO₂max estimates (Mayorga-Vega et al., 2015). Additionally, modern heart rate monitors (HRM) have been equipped with complex algorithms that allow aerobic capacity to be measured at rest. However, the accuracy of HRM methods has not yet been investigated for young team sport athletes. Consequently, the purpose of this study was to compare two different field-test estimates of aerobic capacity in a group of young elite basketball players. Methods 10 male elite basketball players (height = $188.3\text{cm} \pm 6.5$; weight = $79.51\text{kg} \pm 9.4$; age = 17.1 ± 0.86) were recruited for this study. Participants were equipped with a chest-strap and an associated HRM (Polar M400). The activity level was selected based on the current training status (5-8 hours/ week) and anthropometric data entered into the HRM. The participants laid down and rested for approximately 5 minutes. After this time, the HRM automatically provided an estimate of the aerobic capacity. Next, the participants performed an all-out shuttle run test to reassess aerobic capacity. Results The average VO₂max value estimated by the HRM method was $55.3 (+/- 3.9)$ ml/kg/min, compared to $53.4 (+/- 3.9)$ ml/kg/min in the shuttle run. Paired-samples t-test did not reveal any significant differences between VO₂max methods ($p = 0.276$). Discussion The results indicate that the estimates of aerobic capacity provided by the HRM are similar to those established by the fatiguing shuttle-run test. Although, true VO₂max was not assessed in this experiment, the HRM method was compared to a reliable and valid field test. Previous research has found different correlation coefficients between the HRM test and lab-based spirometry from moderate (Esco et al., 2011) to high (Väinämö et al., 1996; Peltola et al., 2000). In summary, the HRM method offers a simple, nonfatiguing way to assess aerobic capacity in young elite basketball players. However, since we did not compare these methods to a gold standard, the obtained values should be regarded with caution. References Esco MR, Muguruza EM, Williford HN, McHugh AN, Bloomquist BE. INTENSITY STRUCTURE OF TECHNICAL AND TACTICAL TRAINING SESSIONS IN U-16 FEMALE POLISH NATIONAL VOLLEYBALL TEAM

GABRYŚ, T., SZMATLAN-GABRYŚ, U., STANULA, A., GARNYS, M., RZEPKA, R., WAGNER, G., STANISZ, L.

IPWSZ Oświęcim, Poland, 2AWF Katowice, Poland, 34SportLab Warsaw, Poland, 4Center Physiotherapy Fizjofit, Gliwice, Poland, 5Polish Volleyball Federation Warsaw, Poland, 6AWF, Krakow, Poland

Aim. Major part of training volume in young volleyball players consists of technical-tactical aspects. Level of these skills is basic criteria for selection of players for national team. Purpose of this study is evaluation of training load applied during preparatory camp before national team selection. Methods. In this study 24 players were included, age 15 years old, VO₂max 50.8 ± 6 ml/kg/min, VT 153 ± 13.7 bp/min, RCP 174 ± 10 bp/min. Training intensity was monitored with Polar Team (Polar, Kempele, Finland). All players were tested with progressive running test at 40m distance, speed increasing from 8km/h every 2 minutes by 1.5 km/h until exhaustion. Exhaled air was continuously sampled by an K4b2 (Cosmed, Italy) and the rate of VO₂, VCO₂, VE were calculated on-line. Threshold values VT and RCP were calculated according to procedures described by [Chicharro 2000]. HR that corresponded to the exercise intensities: below VT were classified as low-intensity (LI); between VT and RCP as moderate-intensity (MI); above RCP as high-intensity (HI) [Lucia et al. 1999]. Results. Training load structure observed during training sessions is presented in percentage values in intensity zone LI, MI, HI respectively in training description: receiving and passing (upper), movement skills, a.m. (60.9, 26.7, 12.4); receiving and passing (lower), movement skills in defense, a.m. (48.7, 35.5, 15.8); various technical skills (passing, serving, digging, attacking), movement skills, s.m. (61.3, 32.1, 6.6); attacking (74.3, 21.4, 4.3), mastering of attacking skills (various court zones) (79.2, 18.3, 2.5); competition: small game 3v3 (44.1, 36.5, 19.4); Competition: small game 2v2 (75.2, 17.5, 7.3); integration of technical skills during game s.m.(69.9, 27.4, 2.7) Conclusion. Training load in volleyball during technical and tactical part mainly ranges between 50-70% of intensity load. Highest load was observed during receiving and passing combined with movement skills training on the court. Lowest training load was observed during integration of technical skills during game. Presented method of training load assessment allows quantifying cardio-vascular load of players during training. For complete assessment of training load aspects of anaerobic lactic load related to high intensity should be also monitored. SPRINT PARAMETERS AFFECTED BY EXERCISE INDUCED MUSCLE DAMAGE IN THIGH MUSCLES

CADEFAU, J.I,3, ILLERA, V.I, CARMONA, G.I, PADULLÉS, X.I, PADULLÉS, J.M.I, TESCH, P.2, CUSSÓ, R.3

1:INEFC-UB (Barcelona, Spain); 2:Karolinska Institutet (Solna, Sweden) 3:Dep. Physiol. Sci. I, University of Barcelona (Barcelona, Spain)

Introduction Maximal Voluntary isometric Contraction force (MVC) is considered as one of the best tools for quantifying muscle damage (Raastad et al. 2010). Other performance related to muscle function, such as jump performance, has been reported to be affected by Exercise Induced Muscle Damage (EIMD). The aim of this study was to assess which parameters of sprint running are more sensible to

EIMD. Methods 9 physically active women (age 26,8±2,2 years) performed 10 sets of Concentric-Eccentric (C-E) bilateral squats on a flywheel inertial device (Yoyo Squat; Yoyo-Technology; Stockholm). Each set consisted in 3 submaximal repetitions to accelerate the disk, immediately followed by 10 high-intensity voluntary C-E reps. 3 minutes of rest were given between sets. Indirect markers of EIMD as Delayed Onset Muscle Soreness (DOMS), MVC of knee extensors and Counter Movement Jump height (CMJh), were assessed before and immediately after exercise, and after 1, 24, 48 and 72 hours (h). Instantaneous speed throughout 40 meters of sprint running was measured by radar (Stalker ATSII, Texas) following the same temporal points. Sprint data was analysed using the method proposed and validated by Samozino et al. (2015) to compute force, acceleration, power and force-speed profile. Results Flywheel exercise caused a significant decrease in MVC levels (-18,2±14,0% p=.004) after exercise, that continued for 24h and were re-established near basal levels 48h after. While CMJh showed no significant changes during all post exercise period, maximum speed and maximum power generated in the 40m sprint showed a similar pattern than MVC. Maximal power diminished (-14,4±9,6%, p=.006) 24h after exercise and remained under basal levels 74h before (-15,4±11,8%). MVC and maximal power showed good correlation before ($r=0,87$ p=.007) and 24h after exercise ($r=0,78$ p=.013). Discussion The decrease in MVC and high levels of DOMS 24h after exercise suggest moderate EIMD. Maximal power during a 40m sprint running showed a similar pattern than MVC values during the follow up and was affected 72h after exercise. Maximal sprint power decreases as a consequence of muscle damage can be used as a sensible marker of EIMD. References Raastad T, Owe SG, Paulsen G, et al. EFFECT OF GRADED COLD EXPOSURE ON PERCEIVED EXERTION AND HEART RATE RESPONSE AT DIFFERENT INTENSITIES OF EXERCISE

KENNEDY, M.D.1, FAULHABER, M.2

1: University of Alberta (Edmonton, Canada), 2: University Innsbruck (Innsbruck, Austria)

Introduction Cold weather exercise is considered "a challenging environmental condition" that poses health risks to individuals including cold weather athletes. Cold weather athlete's routinely train at a variety of exercise intensities in sub-zero temperatures however our understanding of how cold air exercise affects exertion and heart rate is unknown. Thus the aim of this study was to determine the perceived exertion and heart rate response to 5 different sub-zero ambient temperatures during Low (L), Moderate (M) and Heavy (H) intensity exercise. Methods Seventeen females (age: 21.6±3.3yrs; ht: 167.1±7.2cm; wt: 60.5±8.1kg; VO₂max: 49.6±6.6) completed 5 blinded running trials (L: 5 min at 6km/hr, 1% grade; M: 10 min running at 2 km/hr < VO₂max velocity, 1% grade; H: 8min at VO₂max velocity, 5% grade) at 0, -5, -10, -15 and -20°C Celsius (humidity 40%) on different days in randomized order. Trials were completed on a customized cold weather treadmill (h/p/cosmos, Germany) in a digitally controlled environmental chamber. Rating of Perceived Exertion (RPE) and heart rate (HR) were recorded at the end of every minute during each trial. Session based RPE and self-reported physical symptoms were asked post trial. Results There was a significant increase in HR at low intensity exercise (0°C =118.9 bpm; -20°C =123.4 bpm) but similar HR during moderate exercise across temperatures (range 0 to -20°C =157.5 to 156.2 bpm; p =0.52). HR during heavy at -15 and -20°C was significantly lower compared to 0, -5 and -10°C with greater decrease in the last 3 minutes compared to min 1 to 3. RPE was not significantly different across temperatures at L or M (L: 7.0 to 7.2; M: 11.4 to 12.1). During H at min 1, 2, 3, 4, 5 and 6 RPE was not different across temperatures. At min 7 and 8 RPE was greater at -20°C (increase of 0.5 to 1; p<0.05) compared to the other temperatures. Session based RPE was significantly greater at -15 and -20°C compared to 0°C (7.6, 7.9, 6.6 respectively; p<0.05) and frequency of physical symptoms was greater at -15 and -20°C (p<0.5). There was no difference in the distance run across temperatures. Discussion It was found that air colder than -15°C does influence HR, RPE, session based RPE and physical symptoms, however the response is dependent on the intensity of exercise. This has implications for cold weather exercise prescription guidelines in healthy individuals as well as athletes completing maximal intensity workouts in the cold. Although further investigation is required this data would indicate that high intensity intervals no longer than 6 min in temperatures colder than -15°C are well tolerated after which time both HR and RPE change significantly. COMPARISON OF LOAD INTENSITY EXPERIENCED BY PLAYERS WHEN PLAYING THE TOP TWO WOMEN'S COMPETITIONS

VALA, R.1, DURDOVÁ, I.2, VALOVÁ, M.1, SEDLÁČKOVÁ, T.1

1:University of Ostrava, 2: VŠB - Technical University of Ostrava

Introduction This study focuses on the analysis of the load intensity imposed on players in a championship match in the women's top league and the second highest league. This is the crucial point for defining the effective training program since the relationship between the match and intensity of training exercise is considered the key training problem of sport games (Kelly and Coutts, 2010). The aim of this case study is to compare the load intensity experienced during championship matches in the top two competitions. Methods The heart rate (HR) of players (n=10; starting lineup of each team only) was monitored using the Polar TEAM 2 system. The average HR is calculated only from the parts of the match where the players were actively involved in the game and the game clock was running (the so-called "live time") according to Abdelkrim et al. (2007). Results In case of the starting lineup of players (the top league team), the average HR value was calculated as 175.1 ± 14.2 heart beats per minute, which corresponded to $91.9 \pm 6.2\%$ of HRmax and in case of the second highest league team, it was calculated as 179.4 ± 10.3 heart beats per minute ($91.2 \pm 4.1\%$ of HRmax), both determined during the graded exercise test in laboratory conditions. There wasn't a significant difference in the exercise load between the two competitions (5% of significance level). Discussion In addition to the quality of a competition and playing positions, load intensity could be also affected by the actual outcome of the game, the number of foul plays (e.g. necessity to change players) and of course, by tactics selected by coaches. Monitoring load intensity in sport games characterised by interval loads is generally problematic. Unlike more specific indicators, such as oxygen consumption (VO₂), heart rate monitoring, however, represents a practical, widely applicable but also reliable method to assess load intensity (Vala et.al., 2014). INTRODUCTION: Positive results were found with light application (laser and/or LED) to improve skeletal muscle performance and delay fatigue. However, there are few studies showing its' effects on strength training. The aim of the study is to assess the effects of phototherapy applied at different moments in each session of strength training performed three times a week with controlled load. **METHODS:** Forty-eight volunteers, male, healthy and physically active, were recruited. Phototherapy (with combination laser and LEDs) with dose of 30 J and/or placebo was applied before and/or after each session of strength training on quadriceps (bilaterally) according randomization (A: phototherapy before and after; B: phototherapy before/placebo after; C: placebo before/phototherapy after; and D: placebo before and after). Volunteers performed leg press and leg extension exercises, three times a week for 8 weeks. Strength training was performed beginning with 60% of the maximal load, followed of 80% of the maximal load. The variables were assessed at baseline and repeated monthly. **RESULTS:** Volunteers from Group A obtained an increase in Peak Torque Concentric measured in isokinetic dynamometer of about 21% for right and left legs when compared to other groups and baseline. Group D (placebo) obtained an increase of about 6% for right and left legs. No increase in muscle mass was detected. **DISCUSSION:** Our study confirms the interference of phototherapy in strength training. Phototherapy has demonstrated positive effects in improvement of exercise performance and recovery (Leal-Junior et al, 2015). Baroni et al. (2015) associated the application of laser before each eccentric exercise training lasting eight weeks, with better outcomes ($p < 0.05$) than observed in control group and with no irradiation. It is known that phototherapy irradiation in healthy muscles leads to increased cytochrome c-oxidase activity, and may explain the effects of this therapy in stimulating intact skeletal muscles (Hayworth et al., 2010). Through these results, we can infer that phototherapy applied before and after training sessions, with the parameters used for this study can improve muscle quality, since it could increase strength significantly without increase in muscle mass. Moreover, the optimal moment of application can change depending the periodisation of training. **REFERENCES:** Baroni BM, Rodrigues R, Freire BB, Franke Rde A, Geremia JM, Vaz MA (2015). USING EXTERNAL AND INTERNAL PARAMETERS OF EFFORT IN MONITORING THE TRAINING OF JUNIOR III FOOTBALL PLAYERS

MARINESCU, G., TICALĂ, L.D., DULCEAȚĂ, V., PETRE, A.T., BUZĂRNESCU, M., RĂDULESCU, A., DREVE, A., TĂTARU, T., SIMA, D., MĂNESCU, D.C.

National University of Physical Education and Sport

Introduction To achieve remarkable performances during a match, it is not enough to have the motivation and desire to succeed, but it is also necessary to understand the concept of total training, which claims that man is an indivisible whole and each exercise has a global impact on all components of performance (Brunet-Guedj E. et al., 2006). During a football game, metabolic systems are exerted as follows: 70% aerobic system, 15-20% anaerobic lactacid system and 10-15% anaerobic alactacid system (Cazorla G., 2002). It should be mentioned that, for reaching a steady state of maximal oxygen consumption (VO_2max), this one goes through several intermediate stable states which are encompassed in the concept of VO_2 DRIFT. Coaches should avoid the serious error of working in the slow component of VO_2max (Wilmore J.H. et al., 2008). **Methods** The research sample was made up of 18 athletes registered at School Sports Club 1 of Bucharest and born in 1998. Athletes were subjected to two tests (1st testing - 12.08.2014 and 2nd testing - 12.02.2015). The tests used were: 5-minute endurance test and 240-meter shuttle test. Data collection was achieved using GPSports equipment and SPI IQ software. **Results** The obtained reports provide data about the following items: covered distance, travel speed, acceleration speed, maximal aerobic velocity (MAV), VO_2max , heart rate etc. and their evolution. In the 5-minute endurance test, 1st testing, the arithmetic mean for relative VO_2max is 54.9%, while in the 2nd testing, the arithmetic mean has increased to 58.6%; the difference between the two tests is 3.7%, which shows a progress between tests as regards higher aerobic capacity. **Discussions** The use of 5-minute endurance test and calculation of maximal aerobic velocity (MAV) etc. provide information regarding the exercise capacity level of athletes and their limits. Scientific monitoring of training reveals important data about the body's response to specific stimuli and helps coaches to conduct preparation according to the structure and components of periodization. **References** Brunet-Guedj E.B., Brunet B., Girardier J. et al., 2006, Médecine du sport, 7e édition, Ed. METHOD AND DEVICE FOR ANAEROBIC THRESHOLD DETERMINATION

VINOGRADOVA, O., BOROVIK, A., PRILUTSKI, D.

Institute for Biomedical Problems

Introduction The optimal loads for aerobic training are chosen using individual anaerobic threshold (AT) values. The method for determination of AT of small and large muscle groups by the dynamics of the integrated electromyographic (EMG) activity and changes in the content of deoxygenated hemoglobin (HHb) in the muscle is proposed and the algorithm for its evaluation is elaborated. **Methods** 8 subjects performed two incremental exercise tests until exhaustion: the bicycle ergometer test and one leg knee extension test. The EMG activity of the middle part of m. vastus lateralis was continuously recorded during testing, changes in the concentration of deoxyhemoglobin (HHb) was recorded by NIR spectroscopy in the same area of m. vastus lateralis. During bicycle exercise the blood lactate concentration was also measured. **Results and Discussion** The dynamics of nonlinear areas on graphs reflecting the EMG activity and oxygen consumption by working muscle differ qualitatively at the end of the test: deoxyhemoglobin concentration reaches a plateau, whereas EMG intensity increases dramatically. The dependence describing the change in the HHb content in m. vastus lateralis and its EMG activity during the test has a characteristic maximum, therefore, the ratio of these indicators HHb/EMG is convenient to use for determining the AT. Significant correlation ($r = 0.78$; $p < 0.05$) between the power at AT determined by HHb/EMG ratio and the power at the anaerobic threshold determined by the lactate concentration in capillary blood was found. This method for determination of AT is also suitable for determining the AT during exercise of small muscle groups. The miniature wireless device fasten on the working muscle and including electromyograph and infrared spectrometer is elaborated for practical usage of this method. Information is transferred from

device to tablet computer and is processed by means of original software and is kept in database. Conclusions The proposed technique of accessing the moment of AT according to the data of EMG and NIRS of working muscles is quite simple and noninvasive, which opens prospects for its use in the medical and sports practice. The work is performed according to the Plan for Fundamental research of SRC RF Institute of Biomedical Problems RAS

GROWTH AND DEVELOPMENT OF THIGH MUSCLE THICKNESS AND ANAEROBIC POWER GENERATION CAPACITY IN SHORT-DISTANCE AND ALL-ROUND JUNIOR SPEED SKATERS

KUMAGAWA, D., TSUNODA, N.

Japan Institute of Sports Sciences

Introduction The force and power generation capacities of the lower limb muscles are improved by speed skating training in junior speed skaters (Nemoto et al. 1990, de Koning et al. 1991). However, there are differences in aerobic and anaerobic power output between short-distance and middle- to long-distance skating (de Koning et al. 2005). Therefore, the mass and anaerobic power generation capacity of the lower limb muscles are expected to show different developmental trends during puberty between short-distance and all-around skaters. This study investigated the effects of training on the growth and development of thigh muscle thickness and power generation capacity in male Japanese junior speed skaters. Methods Subjects were 425 male speed skaters aged 12–18 years old. They were divided into two groups according to type of skating: short-distance skaters (SS; competitive distance: 500–1000 m) and all-round skaters (AS; competitive distance: >1500 m). Thickness of the anterior thigh (MTTa), lateral thigh (MTTl), and posterior thigh (MTTp) was measured by B-mode ultrasound. Maximal anaerobic power (MAnP) was measured using a bicycle ergometer. Mean skating velocity of 500 m (SV500), calculated from recently attained individual best times, was used as a measure of skating performance. Mean values of these parameters were calculated by age, and rates of growth were calculated by differentiating these values with respect to time. Results MTTa and MTTp were significantly larger in the SS skaters than in the AS skaters at 16 and 17 years old. MAnP and MAnP normalized by body mass were significantly higher in the SS skaters than in the AS skaters at 16–18 years old. Moreover, SV500 was higher in the SS skaters than in the AS skaters at 16–18 years old. The highest rate of growth in thigh muscle thickness was observed at 14.9–15.3 years old in the SS skaters and at 14.0–14.7 years old in the AS skaters. In the SS skaters, the highest rate of change in MAnP and SV500 was observed at 14.9 years old and 14.6 years old, respectively, almost coinciding with the highest rate of growth in muscle thickness. In the AS skaters, however, the highest rate of change in MAnP (13.0 years old) and SV500 (13.2 years old) occurred before the highest rate of growth in muscle thickness. Discussion These findings suggest that different modes of training for speed skating have different effects on muscle mass, anaerobic power generation capacity, and 500-m skating performance after puberty in male speed skaters. Developmental trends in these three parameters nearly coincided in the SS skaters, whereas rapid growth of power generation capacity and skating performance occurred before rapid growth of muscle mass in the AS skaters. THE REALITY OF THE SELECTION OF TALENTED PLAYER (II): RELIABILITY OF PERFORMANCE INDICATORS. A DESCRIPTIVE EXAMPLE

PASTOR-VICEDO, J.C., PRIETO-AYUSO, A., CONTRERAS-JORDAN, O.R., MARTÍNEZ-MARTÍNEZ, J.

University of Castilla-La Mancha

Introduction Comparison between players have been one of the ways to identify the talented football player (Verburgh, Scherder, Van Lange & Oosterlaan, 2014). This comparative has been based on performance indicators (Carling, Reilly & Williams, 2009). This paper aims to determine the reliability of these indicators to identify a player with talent. Methods The research design is a descriptive study. It has been compared on the one hand, the performance between players nominated to the Golden Ball. And on the other hand, it has been compared the performance of a talented football players with his teammates. The data collection has been carried out from Champions League 2014/2015 for being the most internationally prestigious competition of clubs in Europe. Statistical analysis was realized using SPSS program v. 22.0. Results The comparison between players nominated for the Golden Ball showed those players nominated most times obtained the highest score in matches, minutes, influence on his team and goals/shots. On the other hand, the comparison between a talented player with his teammates showed that matches, minutes, goals/shots, dribbles and penalties were higher than their peers. Discussion The results indicated that the indicators used in the literature and specialized databases do not discriminate between the best players in the world and those who are not. In addition, it might be possible to question the conclusions of previous studies (Mackenzie & Cushion, 2013) who have not complemented this assessment with other tools to measure the tactical side (González-Villora, Serra-Olivares, Pastor-Vicedo & Teoldo da Costa, 2015) of the talented footballer. References Carling, C., Reilly, T., & Williams, A. (2009). Performance Assessment for Field Sports. Routledge: London and New York González-Villora,S., Serra-Olivares, J., Pastor-Vicedo, J. THE EFFECTS OF PHV ON PHYSICAL PERFORMANCE ON YOUNG SOCCER PLAYERS

BELLISTRI, G.1,2, ODDO, A.1, LA TORRE, A.1, MURATORE, M.1, SFORZA, C.1,2

National council of research

Introduction. In youth soccer academy categories are organized into annual age groups in order to provide similar competition level and age specific training program (Deprez et al, 2012). Several studies (Figueiredo et al, 2009) have shown better performance in strength, power, speed and endurance in relation to a faster biological maturity in the same age group. Talent identification is often based on physical capacities and so there is the risk that players who are physically less mature may be deselected but not on the basis of their adult potential. No studies evaluated a possible correlation between age of peak height velocity (APHV) and physical capacities. The aim of this study was to examine the relationship between APHV and physical capacities in young soccer players. Methods. 158 young soccer players (8–16 years old) were recruited in this study. Players had their APHV indirectly estimated by the leg length, height and weight using equation from Mirwald et al (2002): Maturity off set = $-9.236 + 0.0002708 \times (\text{leg length} \times \text{sitting height}) - 0.001663 \times (\text{decimal age} \times \text{leg length}) + 0.007216 \times (\text{decimal age} \times \text{sitting height}) + 0.02292 \times (\text{weight}/\text{height ratio})$. Counter movement jump (CMJ), agility (Illinois test

modified for young players), linear sprint performance (5, 10, 20 m), balance (Y balance test, YBT) and flexibility (Sit and reach test, S&R) were evaluated to determine the players' physical capacities. Relationships between APHV and physical variables were evaluated using Pearson's product-moment correlation. The magnitudes of the correlations were considered as trivial (<0.1), small (0.1-0.3), moderate (0.3-0.5), large (0.5-0.7), very large (0.7-0.9), nearly perfect (>0.9) and perfect (1.0) in accordance with Hopkins et al (2009). Statistical significance was set at $P<0.05$. Results. All physical variables were significantly correlated with APHV. Very large magnitude correlations were observed between APHV and linear sprint performance on 5, 10 and 20 meters ($P<0.001$, $r=-0.71$; $P<0.001$, $r=-0.82$; $P<0.001$, $r=-0.86$, respectively), large magnitude correlations were observed between APHV and agility test ($P<0.001$, $r=-0.56$), S&R ($P<0.001$, $r=0.55$) and CMJ ($P<0.001$, $r=0.52$), moderate magnitude correlation was found between APHV and YBT ($P<0.001$, $r=0.38$). Conclusions. Our results indicated correlations between APHV and physical performance in young soccer players and so the physical capacities should be evaluated in relation to individual biological maturation for talent identification and in order to program appropriate training in groups with a great variability of APHV. THE EFFECT OF BODY POSITION DURING BREAKS ON PHYSIOLOGICAL RESPONSES TO SIMULATED BOXING: SITTING VERSUS STANDING

TASIOPoulos, I.1,2, STERGIOLAS, A.1, TRIPOLITSIOTI, A.1, KOSTOULAS, I.2, TORRES-LUQUE, G.3, NIKOLAIDIS, P.T.2,4

1: University of Peloponnese (Sparta, Greece), 2: Hellenic Army Academy (Athens, Greece), 3: University of Jaen (Spain), 4: Exercise Physiology Laboratory (Nikaia, Greece)

Introduction The acute physiological responses to boxing have been well documented (Giovani and Nikolaidis, 2012; Tasiopoulos et al, 2015) however, less information has been available with regards to the impact of different recovery strategies during breaks on these responses. The aim of the present study was to examine the effect of two conditions (sitting versus standing) during breaks on heart rate (HR) responses, rate of perceived exertion (RPE) and neuromuscular fatigue in a simulated boxing match consisting by three 3-min rounds with 1-min breaks. Methods Male boxers ($n=15$, age 21.4 (6.3) yrs, body mass 67.7 (10.0) kg, body height 172 (6) cm, body mass index 22.9 (4.2) kg.m⁻², training experience 2.9 (1.9) yrs) participated in this study. Mean HR was calculated for each round and break. RPE (6-20 Borg scale) was recorded immediately after each round. Countermovement jump (CMJ) and handgrip muscle strength (HGS) were measured before and after match. Results A between-within analysis of variance showed no timexbody position interaction with regards to all variables ($p>0.05$). However, in the case of RPE the p value almost reached statistical significance ($p=0.062$, $\eta^2=0.426$), where, compared to the sitting position, a trend of increased perception of effort for the standing position across time was highlighted. A main effect of time on CMJ, HR and RPE was observed ($p<0.05$), in which (a) CMJ after match was higher than before (34.1 vs. 32.1 cm, respectively, $p=0.007$, $\eta^2=0.443$), (b) HR was higher in the third round than the second and the first one (187, 184 and 177 bpm, respectively, $p<0.001$, $\eta^2=0.609$), and (c) RPE was higher in the third round than in the first one (14.7 vs. 12.6, respectively, $p=0.047$, $\eta^2=0.457$). Conclusions Although the present study did not provide evidence for different physiological impact of body position during break in simulated boxing match, there were indications that manipulating the body position might result in different perception of effort. DETERMINANTS OF MULTIPLE TURNS IN DANCERS

DONTI, O., KOUTSOUBA, M., DONTI, A., ANDROULIDAKI, A., KOTSALA, E., MANDALIDIS, D.

ATHENS KAPODISTRIAN UNIVERSITY

Introduction: Successful performance of a turn requires that the dancer rotates his/her body about a vertical axis with a controlled body posture while maintaining balance on a single leg support. Technical aspects of dance performance improve with enhanced physical fitness (Angioi et al., 2009), however, there is a need to precisely define the fitness components that underlie technical skills execution. The aim of this study was to examine the association between selected physical fitness parameters and the execution of multiple turns on a single leg support in dancers. Methods: Thirteen female, professional ballet dance students (age: 23.34±4.12 years, dancing experience: 16±5 years, height: 163±1 cm, body mass: 50.9±4.6 kg) participated in this study. The number of completed 'en dehors' and 'en dedans' turns performed with dominant leg support and the technical execution of one turn were evaluated separately by two dance experts. The dancers underwent a series of physical fitness tests (balance, lower limb muscular power, muscular endurance, and active and passive flexibility). Pearson's correlation coefficient (r) was used to detect linear associations among the number and the execution of turns and physical fitness parameters. Stepwise multiple regression analyses examined the strength of the association between physical fitness parameters, the number of turns and one turn technical execution score. Results: Balance on the ball of the foot was significantly correlated with the number of 'en dehors' and 'en dedans' turns ($r=0.751$ and $r=0.853$, respectively, $p<.01$), the one turn execution score ($r=0.610$, $p<.05$), and balance on the ball of the foot on a balance platform ($r=0.751$, $p<.05$). Multiple regression analysis indicated that balance on the ball of the foot accounted for 57.4% of the variance in multiple 'en dehors' turns (adjusted $R^2=0.574$, $F=17.172$, $p=.002$). In addition, balance on the ball of the foot and one-turn score accounted for 70.9% of the variance in multiple 'en dedans' turns (adjusted $R^2=0.709$, $F=15.651$, $p=.001$). Lower limb muscular power, muscular endurance and active and passive flexibility demonstrated no association with the number of turns executed and the one turn score. ICC of the total score for the two dance experts was $r=0.93$, $p<.01$. Discussion: It is concluded that balance on the ball of the foot accounts for a large part of the variance of multiple 'en dehors' and 'en dedans' turns execution in classical dancers thus being in line with previous research (Sugano and Laws, 2002). The results of this study provide information to dance teachers on the training focus for turning skills execution. References Angioi M, Metsios G, Twitchett E, Koutedakis Y, Wyon M. (2009). CYCLISTS BODY STABILITY DURING 30 SECONDS ISOKINETIC SPRINT CYCLING EXERCISE IS RELATED WITH FMS SCORE, PEDALLING POWER SYMMETRY AND SMOOTHNESS

RANNAMA, I., PEDAK, K.

Tallinn University

Introduction Notable bilateral pedalling kinetics asymmetry is measured during steady state cycling and it has tendency to decrease due to higher power output or accumulated fatigue (Carpes et al., 2010). Less examined is pedalling kinetics asymmetry during maximal cycling and how it affects the performance. It is found that knee extensors and upper-body movement asymmetry affects negatively 5 sec. sprint cycling performance (Rannama et al., 2015), but there is no evidence how the core stability is related with this. The aim of the present study was to investigate how the body movement efficiency during 30 sec maximal cycling is related with pedalling technique, pedalling symmetry and core stability. Methods The pedalling power (Pped) and smoothness (PS- mean and peak effective force ratio in %) of 37 competitive cyclists (18.8 ± 2.8 y, 181.4 ± 6.2 cm, 74.4 ± 7.2 kg) were measured bilaterally with Garmin Vector pedals during 30s isokinetic (cadence fixed to 100 rpm) seated sprint cycling test. Absolute bilateral symmetry index (ASI %) between DO and ND side in Pped and PS were computed. The Cyclus 2 ergometer was mounted on Kistler force plates and cyclists body Centre of Gravity movement power (PCoG) were measured. The effectual power ratio coefficient (Pcof in %) between PCoG and Pped were computed. The state of cyclists Core stability evaluated with Functional Movement Screening test (FMS). The correlation analyse and a forward stepwise regression analyse between Pcof and Pped (w/kg), PS, Pped ASI, PS ASI and FMS score were made. Results The average values of measured parameters: Pped 822 ± 106 W and 11.1 ± 1.0 W/kg, PS $32.8 \pm 2.6\%$, Pped ASI $5.1 \pm 4.5\%$, PS ASI $7.4 \pm 4.1\%$, PCoG 24.3 ± 6.9 W, Pcof $2.9 \pm 0.7\%$, FMS 14.6 ± 2 . There was no significant correlation between Pped and Pcof, PS, ASI and FMS, but higher Pped associated with higher PCoG ($r=0.43$). Between Pcof and other independent variables was developed regression model: $Pcof = 7.838 - 0.125 \times PS + 0.062 \times Pped ASI - 0.076 \times FMS$ Discussion The results of present study indicate that sprint cycling performance is not linearly related with body movement efficiency, but the relative amount of power that are generated by extra movements are positively related with Ppow asymmetry and negatively with PS and Core stability (FMS). This supports partly our previous findings between 5 sec. sprint performance, knee extensors strength and upper body kinematics asymmetry (Rannama et al., 2015). PHYSICAL AND PHYSIOLOGICAL PERFORMANCE OF YOUNG SWIMMERS DURING THE SWIMMING SEASON

DEDEOGLU, T., ERTAS DOLEK, B.

Ankara University

In Today's swimming sport, the follow up of the developments of physical and physiological performance is pretty much important in terms of the success during the competitions. The personal and the team data which can be followed during certain periods, gives the information about the seasonal and ongoing development of the team as well as the variations that are formed over the years. In addition to the technical follow-up, the swimmers that are followed both physically and physiologically are more motivated individually and more willing to increase the team success. This research is the first measurement out of four that are planned to follow the physical and physiological performances of the National Level Swimmers throughout the season. Totally 27 swimmers (age = 14.6 ± 0.4 year) participated to the study. The average age of the male swimmers who participate in this research is 14.7 ± 0.5 and the average age of the female swimmers is 14.5 ± 0.3 years. Swimmer's age, age of sport, height, weight, body fat weight, fat free weight, total body water, body mass index, basal metabolic rate, arm span, vertical jump, long jump, push-ups and sit-ups measurements have been made. The data has been analyzed through SPSS 21.0 Statistics with the help of T-Test (a statistical examination to measure the significance of the difference of two sets of data). When it is $p \leq 0.05$, the difference between the averages has been found meaningful. The results are important for monitoring of young athletes in all sports in terms of public health.

ANTHROPOMETRIC AND PHYSIOLOGICAL CORRELATES OF 20 M SPRINT IN ELITE YOUNG FEMALE HANDBALL PLAYERS: THE EFFECT OF CHANGE OF DIRECTION

KOSTOULAS, I.D.1, TASIOPoulos, I.2, FERNANDEZ-GARCIA, A.I.3, NIKOLAIDIS, P.T.4

Hellenic Army Academy

Introduction The role of anthropometric and physiological characteristics for sprint in handball has been well documented (1-3); however, less information is available about correlates of sprint with change of direction (COD). The aim of the present study was to examine anthropometric and physiological correlates of 20 m sprint in-line (IL) and with COD in elite young female handball players. Methods Twenty-two female handball players (experience 3.8 (1.6) yrs, age 16.5 (0.7) yrs, height 166 (8) cm, weight 64.1 (11.8) kg, body mass index, BMI, $23.1 (3.3)$ kg.m $^{-2}$) performed a series of anthropometric (height and weight) and physiological measures (sit-and-reach test, SAR, right and left handgrip muscle strength test, HGT, Abalakov jump test, AJ, standing broad jump, SBJ, 20 m sprint IL and 20 m sprint with COD). Results Sprint with COD ($5.07 (0.41)$ s) correlated with weight ($r=0.44$, $p=0.042$) and BMI ($r=0.50$, $p=0.017$). Both sprint IL and COD correlated with HGT ($r=-0.65$ and $r=-0.70$, $p<0.001$, respectively), AJ ($r=-0.81$, $p<0.001$ for both) and SBJ ($r=-0.74$ and $r=-0.77$, $p<0.001$, respectively). A step-wise regression analysis revealed that (a) 20 m sprint IL could be predicted by the equation: $20 \text{ m sprint IL} = 4.702 - 0.037 \times AJ$ ($R^2=0.65$, SEE=0.15); (b) 20 m sprint with COD could be predicted by the equation: $20 \text{ m sprint with COD} = 6.820 - 0.061 \times AJ$ ($R^2=0.65$, SEE=0.25). Conclusions Based on these findings, it was concluded that an excess body weight might have larger impact on sprint with COD than IL. The observation that both sprint modes could be predicted by AJ highlighted the importance of lower limb muscle power for sprint ability either IL or with COD. References 1. DETERMINATION OF THE ANAEROBIC THRESHOLD FROM STRIDE FLIGHT TIME IN RUNNING

SENTIJA, D., MARSIC, T.

Faculty of Kinesiology, University of Zagreb

Introduction This study is based on the assumption that neuromuscular and metabolic changes, which determine the anaerobic threshold in running, are also reflected in changes of specific kinematic parameters. Therefore, the main objectives of this research were to

investigate: 1) the relationship between stride flight time and running speed during incremental running, and the possible presence of a threshold (nonlinear change in the trend) for flight time (FTh); 2) the relationship between the ventilatory anaerobic threshold (ATh, respiratory compensation point) and the FTh. Methods Twenty-three PE students were subjected to an all-out incremental treadmill test, with measurement of gas exchange (VO₂, VCO₂) and kinematic parameters. Independent evaluators defined the ATh (V-slope method) and FTh thresholds. The APAS system (Ariel Dynamics, USA) with surface markers was used to measure the stride flight time, and the Quark b2 (Cosmed, IT) system for spiroergometry data. Student's t-test, correlation coefficient (r), and limits of agreement (LoA) were used to compare the ATh and FTh thresholds obtained in the graded exercise test. Results In 19 subjects FTh was determined as the point of stagnation or decrease of stride flight time with increasing running speed. In the remaining 4 subjects, flight time increased at speeds above FTh. A strong relationship between ATh and FTh ($r = 0.84$, $p < 0.01$) was determined. The average values of ATh and FTh did not differ significantly, although a trend towards somewhat higher values for FTh was present (LoA = 0.2 ± 2 km/h). Conclusions We conclude that, during a graded treadmill test, there is close coupling between changes of stride flight time and gas exchange parameters that determine the threshold between two adjacent intensity domains. The results of this research open a possibility for the development of new methods of determining the anaerobic threshold by monitoring stride parameters during graded treadmill running.

THE EFFECT OF MUSCULAR STRENGTH AND STRENGTH ASYMMETRY ON JUMPING HEIGHT AMONG SOCCER PLAYERS

MISJUK, M.1, RANNAMA, I.1, ZUSA, A.2

1:School of Natural Sciences and Health, Tallinn University (Estonia) 2: Kinesiology Research Laboratory, Latvian Academy of Sport Education (Latvia)

Introduction The game of soccer involves frequent one-sided activities, which may lead to muscle strength asymmetries between two legs (Kellis et al., 2001). Bilateral muscle asymmetries may reduce performance and increase injury risk (Fousekis et al., 2010). There are many studies that investigate relationship between muscle strength and jump height, but there is lack of studies that investigate relationship between muscle strength asymmetries and jump height. The purpose of this study is to investigate relationship between knee flexors/extensors strength, strength asymmetries and vertical jump height. **Methods** The 17 male soccer players of Estonian Premium League teams (22.6 ± 3.9 yrs, 182.7 ± 7.1 cm, 79.4 ± 9.6 kg, soccer experience 15.9 ± 4.0 yrs) performed countermovement jump (CMJ) and countermovement jump with arm swing (CMJA) in Kistler force plate. The jump height was calculated with impulse method. Knee extensors (EX) and flexors (FL) peak torque (PT) was measured with an isokinetic dynamometer Humac Norm (USA). Concentric actions were measured at angular velocity of 60, 180 and $300^\circ/\text{s}$, and eccentric (ECC) actions at angular velocity of $60^\circ/\text{s}$. The hamstring quadriceps (H/Q) ratio and absolute bilateral asymmetry index (ASI) between dominant (D) and non-dominant (ND) legs were computed ($\text{ASI} = 100 * (\text{D-ND}) / 0.5 * (\text{D+ND})$). The forward stepwise regression analyses were made between both jump height values and relative EX and FL PT (N/kg), H:Q ratio and ASI of EX and FL PT in different testing speeds. **Results** The regression model for CMJ height: $\text{CMJ} = 10.49 + 22.82 \times \text{EX300} - 0.199 \times \text{FL300ASI}$ ($p < 0.01$, adjusted R square = 0.74). The regression model for CMJA height: $\text{CMJA} = 21.3 + 21.9 \times \text{EX300} - 0.393 \times \text{EX300ASI} - 0.218 \times \text{FL300ASI}$ ($p < 0.01$, adjusted R square = 0.76). **Discussion** Results on current study are in line with previous study by Lehance et al (2009) that knee EX strength is strongly correlated with CMJ height, but the current study found these strong correlations at lower angular velocity. The main finding of this study is negative relationship between CMJ height and knee EX and FL strength asymmetry measured in high testing speed, it supports modelling based findings of Yoshioka et al (2011). ANTI-GRAVITY SYSTEMS FOR PATIENT TRAINING

OHUNG, K.

KITECH

Introduction All of a person's weight is supported by his or her legs during dynamic motions such as walking, running, and jumping. Human ankles and knees are easily hurt. Specially, it is very bad for knee-patients. Therefore, the proposed systems allows patients to experience reduced gravity environments from microgravity to full gravity (e.g., earth surface, lunar surface and Martian surface). **Methods** The anti-gravity systems consists of 4 wire ropes, 4 road cells, 4 drum-winches, a harness, and, a treadmill. It tracks the person's motion to move with a constant velocity in the horizontal direction as well as to maintain a constant vertical force directly above the person by measuring the deflections and tensions of the 4 wire ropes and adjusting accordingly. The feasibility of the proposed controller has been examined with walking and running experiments on treadmill assuming that patients experience 3 reduced gravity environments, that is, earth gravity, lunar gravity and Martian gravity. **Results** Reactive forces under earth gravity, lunar gravity and Martian gravity are approximately captured as 1, 1/6 and 1/3 of total weight of a patient, respectively. The application of this system would greatly improve medical rehabilitation for conditions including lower extremity rehabilitation, neuromuscular and proprioceptive retraining. MUSCLE ACTIVITY OF LOWER EXTREMITIES AND THE TRUNK WHILE DOING SQUATS WITH VIPR

IZUMI, S., SHIRAKAWA, K., TAGUCHI, N., KASUGAI, Y.

Hosei University

Introduction ViPR is often used in loaded movement training (Dalcourt, 2014). The purpose of this study was to evaluate muscle activities of the lower extremities and the trunk while performing squats using ViPR. **Methods** Seventeen collegiate students (men=8, women=9, age= 20.7 ± 0.7 y) participated in this study. All subjects underwent bilateral squats using ViPR. ViPR is a 4-kg pipe-shaped weight (diameter, 14 cm; length, 107 cm). Muscle activities were measured during normal squats (1. Normal) and four types of squats using ViPR (2. holding ViPR on the head: Head, 3. holding ViPR in front of the thigh: Front, 4. Holding ViPR at the right side of the body: Right, 5. Holding ViPR at the left side of the body: Left). Surface electromyography (SX230, Biometrics Co.) was used to assess muscle activity. The electrode was attached to the rectus abdominis, external oblique, internal oblique, multifidus, gluteus maximus, gluteus medius, rectus femoris, and biceps femoris. All the electrodes were attached on the right side. The section targeted for analysis was 0.4 s when the subject flexed

his/her knee, and the thigh was parallel to the ground. The root-mean-square was calculated and normalized to the % maximal voluntary isometric contractions (MVC) from each squat. Subjects attempted to elicit MVC for each muscle. One-way ANOVA and multiple comparisons with Bonferroni method were used for statistical analysis. Results The external oblique muscle had the most intense activity (30.5%) on the Left, and significant differences in muscle activity were noted between Left and Normal (13.1%, p<.05). The internal oblique muscle had the most intense activity (45.8%) on the Right and was significantly different when compared with all other muscles (p<.0001). The multifidus muscle had the most intense activity (50.5%) on the Left, and was significantly different from that in Normal (31.4%), Front (37.3%) and Right (36.8%, p<.001). Discussion Significant differences were not noted for trunk muscles and muscle activities of the lower extremities when squats using ViPR of 4 kg were compared with normal squats. On the other hand, activities of the external oblique muscle, the internal oblique and the multifidus improved by holding ViPR on either side of the body and when squatting. References 1. Mumford P. BACKSTROKE SWIMMING: THE EFFECT OF USING HAND PADDLES ON SWIMMING PERFORMANCE.

AWAD, M.A.1, ABOALMATY, H.2, ALRENI, A.3

1:Tanta University (Tanta, Egypt), 2: Tanta University (Tanta, Egypt), 3: Sheffield Hallam University (Sheffield, UK)

Introduction It is recognised that the use of swimming aids such as hand paddles during training creates substantial improvement in swimming efficiency and performance (Abdelhameed and Hassaneen, 1997). This is a consequence of the improvement occurred to a specific power of the swimmers and the overall technique (Abu-Elela, 1994). Freestyle swimming has been extensively investigated with regard to the energy expenditure and biomechanical characteristics with hand paddles (Ogita et al., 1999; Elsokary et al., 2001). However, there is lack of information in the literature regarding the physiological demands and performance characteristics in backstroke swimming with hand paddles. Therefore, this study was undertaken to investigate the effect of using hand paddles on backstroke swimming's technical characteristics and performance of Egyptian elite swimmers. Methods Twelve Egyptian elite swimmers competing at the national and level on backstroke swimming style were included in this study. Data collection and measurements were performed in four different sessions with 3-days time interval. In each session, swimmers were requested to swim individually a 100-m backstroke with or without paddles at the same speed and level of intensity (100% of maximum speed). Results Performance and stroke technical characteristics demonstrated lower stroke length, higher stroke number and gliding length without the use of hand paddles. The rating of perceived exertion (16.42 ± 2.8 vs 11 ± 2.84) was higher without the use of hand paddles. Discussion This study investigated the effect of using hand paddles on the physiological and certain biomechanical characteristics of backstroke swimming on Egyptian elite swimmers. The finding indicated that backstroke swimming with hand paddles demonstrated significantly higher efficiency than without on Egyptian elite swimmers, which is consistent with the findings of Ogita and colleagues (1999). PROGRAMMED AND SYSTEMISED PHYSICAL ACTIVITY OR FREESTYLE SWIMMING FOR THE PHYSICAL FITNESS OF EGYPTIAN ADOLESCENTS

ABOALMATY, H.1, AWAD, M.A.2, ALRENI, A.3

1: Tanta University (Tanta, Egypt), 2: Tanta University (Tanta, Egypt), 3:Sheffield Hallam University (Sheffield, UK)

Introduction A plethora of physical and psychological changes during adolescence associated with various components of physical fitness (WHO, 2010). Evidence from high quality literature and guidelines suggested that physical activity of high and moderate intensity (e.g. 9 min race, 1 min abdominal test, etc.) should be performed by adolescents for at least three times a week for 10 - 20 minutes (ACSM, 2004). Furthermore, adolescents should participate in moderate or high intensity sports activity such as swimming for 60 or more minutes a day for at least 3 days a week (Shams, 2007). However, to-date, there is no publication or assessment to investigate the influence of programmed and systemised physical activity and/or sports activity such as swimming on the physical fitness of Egyptian active adolescents. Consequently, this study was conducted to examine the effectiveness of Programmed Physical Fitness Training (PPFT) and sports activity "Freestyle Swimming" (FS) on the physical fitness of Egyptian active adolescents. Methods The total population in this study was all adolescents who are members at Tanta sports club (Egypt). 100 participants (aged 12 to 17) 50 male and 50 females were included in the study. Programmed Physical Fitness Training group (PPFT) comprised 50 participants (aged 15 ± 0.6 years) 25 males and 25 females. Freestyle Swimming group (FS) comprised 50 participants (aged 14 ± 0.8 years) 25 males and 25 females. Results The PPFT group demonstrated significant improvement in cardiovascular fitness and strength of the upper and lower limbs. The FS group demonstrated significant improvement on agility and strength of the upper limb. Discussion The findings of this study demonstrated that the effectiveness of the PPFT and FS on Egyptian active adolescents' physical fitness were not significantly different. Although the PPFT creates more positive changes in the physical fitness, majority of Egyptian active adolescents frequently prefer the FS. References ACSM. ASSESSMENT OF MATCH INTENSITY IN ICE HOCKEY PLAYERS

STANULA, A.1, GABRYŚ, T.2, OZIMEK, M.3, GABRYŚ-SZMATLAN, U.3, ROCZNIOK, R.1

1: AWF (Katowice, Poland), 2: PWSZ (Oświęcim, Poland), AWF (Kraków, Poland)

Introduction Ice hockey is a team sport where the players demonstrate comprehensive physical fitness. The extremely varied nature, intensity, and duration of activity encountered in ice hockey makes it difficult to precisely determine the metabolic demands of this sport. The purpose of this study is to determine the intensity of ice hockey youth elite players' effort during the game on the basis of their heart rates and the results of graded maximal test values. Methods Twenty youth ice hockey players, members of the Poland men's national under-18 ice hockey team (mean \pm SD; 16.7 ± 0.75 y; 182 ± 5.5 cm; 79 ± 7.2 kg) participated in this study. Players performed an incremental exercise test on a cycle ergometer platform Cyclus 2 (RBM elektronik-automation GmbH, Leipzig, Germany) used to assess maximal oxygen uptake (exhaled air was continuously sampled by an gas analyzer K4 b2 (Cosmed, Italy)) in a period directly preceding their participation in the International Ice Hockey Federation World Junior Championships. The results of the test allowed us to indicate two physiological markers (ventilatory thresholds (VT1) and respiratory compensation point (RCP)) (Chicharro et al., 2000) and heart rates (HR)

necessary to determine 3 intensity zones. By juxtaposing each player's HR recorded during games played at the Championships with intensity zones obtained from the incremental exercise test, the length of time that individual players worked in each zone was calculated (Stanula, Rocznik, 2014). Results In each period, the defensemen spent around 22% of their playing time in the high intensity zone (HR exceeding 94.5% of HRmax) and approximately 22% in the moderate-intensity zone (HR between 82.6 and 94.0% of HRmax). In total, they spent more time in these two zones than the forwards for whom the respective values were around 19% (HR higher than 96.1% of HRmax) and 26% (HR from 85.4 to 95.6% of HRmax). The difference between the time the forwards and the defensemen spent in the high intensity zone during the entire match was statistically significant ($p=0.043$). Discussion The main finding of this study is that ice hockey players' HRs recorded during a game and those obtained from an incremental test can be applied to estimate exercise intensity. A method that uses the aerobic and anaerobic metabolism variables to determine exercise intensity zones can significantly improve the reliability of assessment of the physiological demands of the game, which makes it a very useful tool for sports scientists and other sport-related professionals in managing the training process (Stanula et al., 2016). CHANGES IN RATE OF FORCE DEVELOPMENT AFTER ANGLE SPECIFIC LEG EXTENSION ISOMETRIC TRAINING

BOGDANIS, G.C., SELIMA, E., TSOUKOS, A., TERZIS, G., VELIGEKAS, P.

University of Athens

Introduction Recent studies have shown that isometric training of the knee extensors at long muscle length (i.e. knee angle at 90°) shifts the force-length relationship towards smaller knee joint angles and increases squat jump performance (Ullrich et al., 2010). However, most power sports require the development of explosive muscle force with much larger knee angles and there is limited evidence regarding the effects of isometric training at different knee joint angles on explosive force generation. Thus, the purpose of the present study was to compare two isometric training programs performed at different knee angles on rate of force development (RFD) of the leg extensors. Methods The sample included fifteen male physical education who were divided into two groups and trained three times per week for 6 weeks. One group ($n=8$) performed the isometric leg press exercise with knee angle set at 85°, while the other group ($n=7$) performed the isometric leg press with knee angle set at 145°. Training involved 5-7 sets of maximal isometric leg press exercise with a 4 min of recovery between sets, during which 3 countermovement jumps were preformed. Before and after training, isometric strength during leg press at 6 different knee angles (60–160°) were assessed using a force platform. RFD during the first 100 ms of contraction was calculated from the filtered force data obtained at 1000 Hz. Data were analyzed using 2-way ANOVA with repeated measures and Tukey post-hoc test ($p<0.05$). Results After training at a knee angle of 85°, maximal isometric force was increased similarly by 12.5% at all knee angles (main effect pre vs. post training, $p=0.028$), but RFD did not change significantly ($p=0.37$). In contrast, following training at a knee angle of 145°, maximal isometric force increased only at the knee angles of 140° (by 15.9%, $p=0.04$) and 160° (by 48%, $p=0.01$), while RFD increased only at the angle of 160° (by 55%, $p=0.15$). Discussion Training at a knee angle of 145°, resulted in an angle-specific increase in peak isometric force and RFD, while training at a smaller knee angle resulted in an improvement of maximal isometric force only, with no effect on RFD. This data show that angle specificity of isometric training occurs only when training at a large knee angle. References Kubo K, Ohgo K, Takeishi R, Yoshinaga K, Tsunoda N, Kanehisa H, Fukunaga T. PRE-FRONTAL CORTEX OXYGENATION AND PERIPHERAL FATIGUE DURING WINGATE EXERCISE

Nearly, J.P.1, Dahlstrom, B.K.1, Dat, M.2, Schaez, S.1, Butz, M.1

University of Regina

Introduction It is well accepted that biological fatigue ensues when maximal exercise is performed. Research supports that both central and peripheral fatigue is implicated, but it has been debated what is the contribution of each component to this fatigue (Noakes et al, 2005; Amann et al, 2013). However, it appears that the type, intensity and duration of exercise influences this response to exhausting exercise (Hargreaves, 2008). This study examined the effects of a single Wingate 30-sec anaerobic test on tissue oxygenation changes and its relationship to central nervous system vs. peripheral neuromuscular activation. We hypothesized that short-term high intensity exercise would elicit a peripheral fatigue but not a central limitation because of the brief nature of exercise. Methods Ten ($n=3$ female) university athletes performed the Wingate anaerobic test (7.5% body mass resistance) on the Veltelon cycle ergometer. Near infrared spectroscopy was used to assess pre-frontal cortex (PFC) and quadriceps muscle oxygenation changes throughout testing. Central activation (CA) was recorded using the interpolated twitch technique during a maximal voluntary isometric contraction (MVC, N) of the right quadriceps muscle in a knee extension chair (knee at 90 degrees flexion), performed pre- and post-Wingate. Electrical stimulation was provided by a constant current stimulator triggered by a Powerlab 16/30 stimulator panel. In addition to MVC, subjects were tested for peak twitch force (PT, N), time to peak twitch (TPT, msec), half relaxation time (½ RT, msec), and relaxation time (RT, msec). Paired t-tests compared differences pre- to post-Wingate with statistical significance set at $p<0.05$. Results Pre- vs. post-Wingate results showed that CA was not changed (88 ± 8 to 92 ± 6 %), but MVC was significantly reduced (815.4 ± 120.3 to 668.2 ± 56.8 N), respectively. PT force was significantly reduced post-Wingate (506.6 ± 83.2 to 427.5 ± 84.5 N, respectively). There was a greater absolute % reduction in muscle (15%) vs. PFC (3%) tissue saturation index (TSI%), and this was also reflected in a greater deoxygenation (HHb) change in the muscle ($8.3\pm 10.5\mu M$) vs. the PFC ($2.6\pm 3.5\mu M$), despite both tissues being well perfused with oxygen (PFC HbO₂= $16.5\pm 9.2\mu M$; MHbO₂= $6.4\pm 5.1\mu M$). Discussion This study supports the contention that the central and peripheral contribution to fatiguing exercise is related to the type of exercise, as it has been documented that either, or both, a central and peripheral fatigue occurs during maximal exercise (Noakes et al., 2005; Amann et al. 2013; Hargreaves, 2008). Collectively our results showed that there is greater peripheral fatigue (significant reduction in MVC and PT with no significant change in CA) after a single 30-sec Wingate test despite both the brain and muscle being well perfused with oxygen. VISUAL PACESSETTERS DURING SUBMAXIMAL EXERCISE: COULD IMPROVE PERFORMANCE?

LECCE, D., GIANCOTTI, G.F., RODIO, A.

University of Cassino and Lazio Meridionale

Introduction: Recent research evidence indicates that synchronizing movement patterns to an external rhythmic auditory stimulus such as music could possibly lead to reduced metabolic cost via enhanced neuromuscular or metabolic efficiency (1-2). Besides acoustic, also the visual stimuli can be capable to induce mood changes, consequently it could be used to improve work load during physical activity (3), but no studies have evaluated the effects of visual stimuli on the efficiency and metabolic work. The main aim of this study was to assess the effectiveness of exercise routines which make use of different types of pacesetters, as well as to compare energy expenditure during training with acoustic or visual cues. **Methods:** Twelve healthy male subjects (age: 29.3 (± 5.9) yrs; height: 178.2 (± 8.1) cm; weight: 81.4 (± 9.1) kg) were enrolled and underwent to a 30 min long exercise on a cycloergometer at a constant speed (about 60 rpm) and workload intensity corresponding to 70% of ventilatory threshold. Three randomized experimental sessions were performed by each subject: Control Test (CT) without stimuli, Mirror Test (MT) video representing an exercise performed by subject with no audio, Visual Test (VT) video including a series of rhythmic images with no audio. In all trials, VO₂ was measured breath by breath by means a metabolism meter (K4b2, Cosmed, Rome, Italy). The corresponding energy was estimated by multiplying the VO₂ (ml*kg⁻¹) by 21 (equivalent energy in Joule). These values were taken in account in the result section for each subject and test. ANOVA for repeated measures was applied to evaluated differences ($p < 0.05$) in relation to experimental session. **Results:** The metabolic work (MW) expressed in kJ, resulted: 940 (± 139.1), 882 (± 130.6), 874 (± 96.1) in CT, MT, VT respectively. The efficiency resulting lower of 6% and 7% in MT and VT respectively than CT. In particular, it is significantly different in MT and VT compared to CT. **Discussion:** Results from this investigation could be used for the development of new training strategies, in which images projected at various frequencies can be showed to the athletes to indicate the correct rhythm of the technical movement. This study would seem to highlight how the ergogenic effect could be attributed to synchronicity between stimulus and motor tasks, without necessarily being related to psychological factors as referred in past studies (4). The positive benefits could be ascribed to a more efficient agonist and antagonist co-contraction. **Reference:** Karageorghis CI et. al. (2009) J Sport Exerc Psychol. 31:18–36 Terry PC et. al. ANTHROPOMETRY AND EXERCISE TESTING IN PROFESSIONAL CYCLO-CROSS ATHLETES

TAEYMANS, J., ROEKENS, J., NEELS, H., GIELEN, J., VISSERS, D.

Bern - University of Applied Sciences

Introduction: Cyclo-cross athletes can choose to cycle or carry their bike and run. Training, therefore, can be focused on biking and/or running. The aim was to determine anthropometric and physiological characteristics in professional cyclo-cross athletes and to investigate differences between the results of an exercise test on a cycle and a treadmill ergometer. **Methods:** Anthropometric parameters were analyzed in six elite (age 25 \pm 3 y) and five U23 (age 19 \pm 1 y) professional cyclo-cross athletes following the ISAK guidelines. They performed maximal exercise tests on a cycle ergometer and a treadmill with ergospirometric and blood lactate assessments, in the beginning and at the end of the season. **Results:** The mean somatotype was mesomorph-ectomorph. The somatotype components were 3.40 \pm 0.56 (mesomorph), 3.50 \pm 0.76 (ectomorph) and 1.50 \pm 0.35 (endomorph). Relative body fatness was similar between elite and U23 riders (4.19 \pm 0.66 vs 6.02 \pm 1.60 %BF ($p=0.082$) resp.). Maximal ventilation, VO_{2peak} and maximal lactate during cycle ergometry were higher compared to the treadmill tests (128.80 \pm 19.81 vs 119.53 \pm 14.70 l/min ($p=0.05$), 70.06 \pm 8.15 vs 64.92 \pm 8.89 ml/min/kg ($p=0.041$) and 7.92 \pm 2.28 vs 5.72 \pm 1.23 mmol/l ($p=0.001$) resp.). A significant increase in load and VO₂ at the 2 mmol lactate threshold towards the end of the season was observed. Although absolute maximal load remained unchanged (376 Watt), maximal load per kilogram body-weight was significantly increased towards the end of the season (5.66 \pm 0.53 W/kg vs 5.70 \pm 0.53 W/kg; $p=0.017$). **Discussion:** Professional cyclo-cross athletes have a mesomorphic – ectomorph somatotype profile and a low fat mass. Results of a maximal exercise test on a treadmill are significantly lower compared to the results on a cycle ergometer in cyclo-cross athletes.

MAXIMUM OXYGEN UPTAKE DETERMINATION BASED IN DECREMENTAL TESTS

BALDISSERA, V.1, BERTUCI, D.R.1, PADUA, P.L.2, SANTANA, G.M.2, ROSA, D.M.2, SOUSA, N.M.F.2

1: UNESP /Rio Claro, Brazil; 2: FESV /Vitoria, Brazil

Introduction: The validity of maximum oxygen uptake (VO_{2max}) values may be questioned, because it depends on various factors, such as the incremental exercise protocols (INC) used. Beltrami et al (2012), published in their work a new approach about determination of VO_{2max}; they used a the decremental (DEC) protocol, in which speed started high but was reduced progressively, achieving higher VO_{2max}. However, the hypothesis that DEC can achieve higher values than INC was not retested. Thus, the aim of this study was to evaluate if DEC can reach higher VO_{2max} values when compared with traditional INC. **Methods:** Thirteen healthy, well trained male athletic runners of national level (age: 18 \pm 1 years; height: 174 \pm 5 cm; total body mass 67 \pm 3 kg; fat body: 8.0 \pm 1.4%), performed 5 tests. The first four, were separated by 48 – 72 hours, the last one was performed 7 – 10 days ahead: (1) a traditional INC plus verification test (VER) at a constant workload 1 km/h higher than the last completed stage in INC; (2) DEC familiarization; (3) DEC in which speed started as same as the VER but was reduced progressively; (4) DEC until speed of VO_{2max} (vVO_{2max}) and immediately followed by 10 seconds stages of INC (DEC/INC); (5) INC final (INCf) to compare with the first INC. All tests were performed in a treadmill (Super ATL, Inbrasport, Porto Alegre, RS, Brazil) with 5% grade and using the gas analyzer Metalyzer II (Cortex, Leipzig, Germany). VO_{2max} and vVO_{2max} achieved in DEC, DEC/INC and INCf were compared with INC (student t-test). **Results:** No statistically differences ($p>0.05$) were observed between VO_{2max} of INC (59.0 \pm 4.2 ml.(kg.min)⁻¹) and DEC (60.1 \pm 5.3 ml.(kg.min)⁻¹), DEC/INC (60.3 \pm 5.9 ml.(kg.min)⁻¹) and INCf (59.6 \pm 4.5 ml.(kg.min)⁻¹). No statistically differences ($p>0.05$) were also observed between vVO_{2max} of INC (15.6 \pm 1.3 km/h) and DEC (15.2 \pm 1.5 km/h), DEC/INC (15.8 \pm 1.5 km/h) and INCf (16.0 \pm 1.3 km/h). **Discussion:** Beltrami et. al (2012) compared INC vs DEC and they found VO_{2max} in DEC 4.4% higher than INC. Authors attributed this result to anticipatory mechanisms (sympathetic/parasympathetic drives) that can change the effort sensation. The findings of Beltrami et al (2012) are in contradiction of the classical model of exercise regulation. However, the hypothesis that DEC can achieve higher values of VO_{2max} than INC was not confirmed in our study. Smirnau et al (2013), in their opinion report, explain that different protocol can attain different values of VO_{2max}. However, it is necessary more studies of the model proposed by Beltrami et al (2012). Some of our participants showed a large VO_{2max} difference between INC and DEC tests. So, more studies are required to elucidated these questions. **References:** Smirnau, BPC et.al. (2013). Front Physiol, 4, 203. Beltrami, FG et al. (2012). Br J Sports Med, 46(1), 23-299.

USE MORPHOLOGICAL AND FUNCTIONAL CHANGES IN THE CONTROL OF TRAINING EFFECTS

WIERZBICKA-DAMSKA, I.

University of Physical Education

Ad hoc training effects are additive and, consequently, lead to more systemic changes that outwardly manifested by morphological changes. Immediately you can evaluate them based on registration of changes of somatic: body composition, thickness of skinfolds and body circuits. Yet taken control methods of training effects are mainly based on the study of fixed states (physical fitness level determined by the biochemical and physiological indicators, the result in sport). While the effects of current control is carried out only partially, in order to qualify for the effort made to set the intensity or type of zones of such measures. Therefore, studies were undertaken, aimed at developing methods of control of late (prolonged) and fixed effects of training on the basis of anthropological measurements and physiological indicators during the course of sports training, in particular periods and consequently, a more optimal use of different methods and training loads. Material and methods: The study involved 20 MTB cycling. Research cyclists included annual training cycle, and individual training units were divided into training: phosphate, glycolytic and oxidative. Subjects were taken anthropological body measurements of: height, weight , three components of body composition: lean body mass, fat and water, circuits of the body: chest, waist, hips, right and left forearm and upper arm and right and left lower leg and thigh and skin folds. By registering late changes of body circuit training was measured before, immediately after training and the next morning. However , in order to document the fixed effects were measured: body composition and thickness of skin folds and the level of physical fitness. Taking into account the type of energy conversion characteristics for metabolism of effort in cyclists, physical efficiency levels were measured Wingate test, to evaluate the anaerobic capacity. Results: The prolonged effects After training specific to cyclists sports, but mostly taking place on the basis of sources phosphate in the riders have a statistically significant increase in circuit libs – thighs (right and left) After glycolytic training in cyclists statistically significant increase in waist circumference After aerobic training, riders waist circumference changes were the opposite direction, and further increased circuitry of the thighs. The fixed effects: The training used influenced by modifying the construction and composition of the body of tested competitors Reduction of fat tissue was in favor of lean body mass. Thanks to increased hydration. Also increased the level of physical efficiency , which directly translates into improved athletic performance and training effectiveness. EFFECTS OF INDOOR CYCLING TRAINING ON ROLLERS UNDER CONDITIONS OF VASCULAR OCCLUSION IN AMATEUR TRIATHLETES

SELLÉS-PÉREZ, S., GARCÍA-JAEN, M., CHULVI-MEDRANO, I., HERNANDEZ-SANCHEZ, S., CORTELL-TORMO, J.M., TORTOSA-MARTINEZ, J., CEJUELA, R.

University of Alicante

Introduction Occlusion training was originally developed in Japan where it is known as KAATSU training (Sato, 2005). The effects of occlusion training have been studied in different types of populations (Takarada et al., 2000) . Most investigations are associated with strength training (Manini & Clark, 2009) but there is little research about the effects of occlusion training in endurance training. The main objective of this research was to test the effects of an indoor cycling training protocol under conditions of vascular occlusion in the maximum aerobic power and anaerobic threshold of amateur triathletes. Methods 20 amateur male triathletes (Age 25.0 ± 5.7 ; Stature 176.5 ± 6.8 cm; Weight 72.8 ± 7.3 kg) were divided into two homogeneous groups after the first test (maximum aerobic power cycling test): control group (CG n=10) without occlusion training or experimental group (EG n=10) with occlusion training. Triathletes conducted specific cycling training on rollers 3 days per week for 3 weeks. The rest of the time both groups completed the same training plan. The specific training for CG consisted of 5 minutes in zone 1 (below VT1) followed by 45 minutes in zone 2 (between VT1 and VT2) and ending with 2 minutes of recovery. The EG started with 5 minutes in zone 1 (below VT1) without occlusion followed by 22.5 minutes in zone 2 (between VT1 and VT2) with a 50% occlusion in the most proximal part of the lower limb, ending with 2 minutes of recovery without occlusion. All triathletes repeated the test after 3 weeks of training. Results The results showed very significant increases in the maximum aerobic power both in the control group (Pre: 292 ± 35.214 w vs. Post: 316.50 ± 39.019 w; $P < 0.01$) and in the experimental group (Pre: 292 ± 42.895 w vs. Post: 317 ± 36.530 ; $P < 0.01$), as well as significant improvements in the anaerobic threshold in the experimental group (Pre: 229 ± 35.730 w vs. Post: 239 ± 32.128 w; $P < 0.05$) and control group (Pre: 216 ± 23.97 w. vs. Post: 241.11 ± 27.58 w; $P < 0.01$). Discussion The experimental group obtained very similar improvements in both the maximum aerobic power and the anaerobic threshold compared to the control group, but expending a considerable lower training time. Thus, occlusion training seems to be a valid methodology to improve maximum aerobic power and the anaerobic threshold of amateur triathletes in the cycling segment. However, more research is needed in order to find the best occlusion training protocol for endurance training. References Manini, T. M., & Clark, B. C. (2009). DOES A MENTALLY FATIGUING TASK INFLUENCE PHYSICAL AND COGNITIVE PERFORMANCE DURING A TOPTEST?

VRIJKOTTE, S., VANDERVAEREN, C., ROELANDS, B., BUYSE, L., MEEUSEN, R.

Vrije Universiteit Brussel [Additional: Zorggroep Solis (Netherlands), FWO (Belgium), James Cook University (Australia)]

Introduction The recent joint consensus statement on 'overtraining syndrome' (OTS) of ACSM & ECSS identifies several markers for non-functional overreaching (NFO) and OTS. Meeusen et al. (2004; 2010) developed a 'Training Optimisation' test (TOptest) for diagnosing NFO & OTS. This double maximal cycling test (separated by a resting period) showed that reaction times and hormonal response to exercise are possible tools that can be used in the diagnostic procedure for training distress. However, it is not yet clear if the addition of a mentally fatiguing task could change performance. Therefore, the purpose of this study is to examine the possible influence of mental fatigue during the TOptest. Methods A single blind, randomized, placebo controlled cross-over design was used. After a maximal cycle ergometer test (MAXtest), nine healthy male participants (age 18-35) performed two TOptests in 18°C , separated by 1 week. The two maximal exercise bouts were separated by either a 1.5h rest period (control- C) or a 1.5h mentally fatiguing task, the Stroop (MF). The parameters measured throughout the study (baseline, post-MAXtest 1, pre/post-MAXtest 2) included cortisol, heart rate, M-VAS, the Profile Of Mood States (POMS), and a Flanker task measuring reaction time (RT) and accuracy. During the MAXtest blood lactate and Rating of Perceived Exertion were determined every 3 minutes. Data were not normally distributed, therefore a Wilcoxon test was used.

Results The MF condition resulted in higher M-VAS scores before the 2nd MAXtest compared with C. Significantly ($p<.05$) higher values were observed for the fatigue, tension and anger scores of the POMS in the MF condition. No significant differences in accuracy and RT were detected when looking at the Flanker task post MF and C. Physical performance was not affected when looking at the maximal Watt before and after the MF and C task ($p=.317$ and $p=.157$, respectively). Discussion A mentally fatiguing task during the rest period of a TOPTest influenced the subjective ratings of the POMS. Mental fatigue did not impact cognitive and physical performance, which is in contrast to the results observed by Marcora et al. (2009) who found physical performance to be negatively affected. Since subjective ratings are important for diagnosing NFO & OTS, mental fatigue is an important factor to take into account when testing for NFO & OTS. TIME-MOTION ANALYSIS IN FENCING COMPETITION

SANHUEZA ALFARO, S., RODIO, A., TERRANONA, A., CORTIS, C.

University of Cassino e Lazio Meridionale

Introduction Fencing is a situation sport where two athletes fight in a continuous strategy game, masking their true intentions to surprise and hit the opponent. Fencing is generally classified as open-skill sport (Dal Monte et al 1980), characterized by a very high energy demand (Caldarone et al 1983; Nystrom et al 1990), closely linked to the athletes' coordinative and psychological characteristics (Saepa et al 1984). Within each competition there is a wide variability of actions duration, represented by numerous stopping and starting phases. Since the understanding of the complex multi-dimensional model of fencing requires a careful analysis of the various aspects of performance. The aim of this study was to analyze the time-motion structure of fencing competitions. Methods Eighteen male (n=9) and female (n=9) of 36 male (n=18) and female (n=18) Italian epee fencers were recorded during the 2013 National University (age: 20-28) Championship. Duration (s) of fighting and nonfighting phases were recorded in all matches (5 touches for a maximum of 3 min), using Dartfish TeamPro Software. Differences ($p<0.05$) were analyzed in relation to gender (male vs female) and type of action (fighting vs nonfighting) through Analysis of Variance. Results Regardless of gender, higher ($p<0.05$) duration were found during fighting (male: 15.2 ± 13.6 s; female: 14.1 ± 9.8 s) phases with respect to nonfighting (male: 7.3 ± 4.1 s; female: 5.9 ± 4.4 s) ones. Discussion Findings indicate a longer duration of athlete fighting actions with respect nonfighting ones, independently from gender. This would probably depend to a strategic choice dictated by the preliminary stage of the competition, where the short duration of the match allows athletes to spend more time in fighting phase, in order to be able to get 5 touches before their opponent. THE EFFECT OF A PERIODIZED CONTRAST WATER THERAPY PROTOCOL ON MUSCLE RECOVERY FOLLOWING A BOUT OF HIGH VOLUME RESISTANCE TRAINING: A PILOT STUDY

PLOWMAN, P., HOUGH, P.

St Mary's University

Contrast water therapy (CWT) has become a common post exercise recovery strategy among athletes to alleviate the delayed onset of muscle soreness and promote recovery. During CWT athletes alternate between cold and hot water immersion after a strenuous exercise bout. CWT can induce rapid changes intra-muscular hydrostatic pressure, which may alter blood flow in immersed musculature and improve the removal of metabolic waste products. However, a number of authors have concluded that further investigation of CWT is required to discover the optimal cold:hot ratio, temperature, duration and frequency practice. The aim of the present study was to investigate the effect of a periodized CWT approach, whereby the ratio of cold:hot water exposure was modified between sessions by systematically increasing hot and decreasing cold exposure durations. Twenty healthy male subjects (aged 18-30 years) were alternately allocated to the control or CWT group. Following a resistance training protocol of 10x10 repetitions of calf raises, with a load equating to 10% of the subjects body mass, the participants underwent their recovery protocol immediately, 24 and 48 post exercise. Creatine kinase (CK), muscle soreness (visual analogue scale) and swelling (calf circumference) was measured before each recovery protocol. Both protocols involved the complete immersion of the gastrocnemius within water tanks. The total immersion time for each session was 19 minutes in both groups. The CWT protocol alternated between cold (10-15°C) and hot (30-38°C) water. The cold:hot ratio was decreased between sessions. The control group remained within the thermo-neutral (20-25°C) water during all sessions. CK and perceived soreness values were significantly reduced ($p < 0.05$) in the CWT group at 24, 48 and 72 hours in comparison to the control group. However, there was no significant difference in calf circumference between conditions. A periodized CWT protocol promotes a greater localized muscle recovery response compared to a thermo-neutral water immersion protocol following a high volume resistance training protocol.

ANALYSIS OF THE TECHNIQUES PERFORMED IN A TAEKWONDO UNIVERSITY CHAMPIONSHIP

MENESCARDI, C.1, ESTEVAN, I.2

1: Universidad Católica de Valencia "San Vicente Mártir" (Valencia, Spain); 2: Universitat de València (Valencia, Spain).

Introduction The aim of this study was to analyze the performance of taekwondo athletes according to the medal obtained (golden, silver, bronze and non-medalists) in a Spanish University Championship (2011), with emphasis on the kicking zone, the trajectory and the kicking leg. Methods 356 performs of 178 bouts were analyzed: golden (n = 54), silver (n = 49), bronze (n = 71) and non-medalists (n = 182). The variables analyzed were: i) kicking zone (trunk or head), ii) trajectory (linear, circular or with previous spin), and iii) kicking leg (right or left). Only one observer was involved in the study. Intraobserver measures were reliable with an ICC = 0.85 ($p < 0.01$). According to the Belmont Report, because the analyzed video tapes are in the public domain, no participant's informed consent was required. A previous K-S test was carried out to determine non-parametrical tests (Kruskall Wallis test followed by Mann Whitney U test for pair comparisons were conducted) ($p < 0.05$). Results There were differences in linear techniques ($\chi^2[3] = 58.762$, $p = 0.01$), and right leg ($\chi^2[3] = 9.041$, $p = 0.03$). That is, medalists (golden [G], silver [S] and bronze [B]) performed more linear actions ($G = 5.93 \pm 6.96$, $S = 6.43 \pm 4.52$, $B = 5.37 \pm 3.75$) than non-medalists ($|U = 3524.00|$, $|U = 1965.50|$, and $|U = 3235.00|$; $p = 0.01$, respectively) who performed 2.70 ± 3.38 actions. With regard to the kicking leg, non-medalists performed more actions with right leg (17.51 ± 10.00) than golden medalists (14.20 ± 8.62) ($|U = 3909.000$; $p = 0.02$). No differences were found in variables related to the kicking zone ($p > 0.05$). Discussion Results of the current study showed that medalists performed more linear actions and fewer actions with right leg (golden medalists) than non-medalists. Medalists could use

linear techniques due to the major speed of these techniques than other ones (e.g., circular) (Leel et al., 2005) which could lead the victory. These results pointed out also the major ability of golden medalists to perform fewer techniques with right leg assuming the capability to perform techniques using both legs. These results could lead to a reorientation of technical-tactical training of taekwondo athletes to deal with actions linked to medalists. References Leel, C, Lee, Y, Cheong, C. (2005). Proceedings of the XXIII International Symposium on Biomechanics in Sports, 595-597. Beijing, China. Contact ca.menescardi@ucv.es

A TARGETED STRENGTH TRAINING PROGRAMME AND ITS EFFECT ON PERFORMANCE AND INJURY RISK: A CASE STUDY IN SPRINTING

BROWN, S.R.1, MORIN, J.B.1,2

1Auckland University of Technology, 2University of Nice Sophia Antipolis

INTRODUCTION Athletic performance and injury risk are key components within sports science; and while they may appear unalike, they are in fact inherently coupled. A maximal sprint effort on a non-motorised treadmill (NMT) for example, can provide both performance (i.e. power) and injury risk (i.e. asymmetry) variables within the same trial (Brown et al., 2015). However this link is seen less often in practice due to the overwhelming demands of performance. Recent observations show that hip extension strength is related to sprint horizontal force (FH) and thus performance (Morin et al., 2015), and that targeted strength training can decrease lower-extremity asymmetry (Brown and Brughelli, 2014). We therefore assessed an athlete on a NMT to illuminate any sprint asymmetry and then prescribed a targeted strength training programme aimed at altering the deficiencies. **METHODS** One male athlete performed four 6-s sprints on a NMT once per week for two 6-week blocks. The sprint testing consisted of an initial "unloaded" sprint to profile symmetry and three subsequent sprints with randomised electronic-brake loads to profile performance. A general training regime with no additional sprint training was programmed during weeks 1-6, and then targeted hip extension exercises based on the asymmetries found were added for weeks 7-12. **RESULTS** Pre to post training, the athlete maintained maximal velocity (8.4 to 8.3 m·s⁻¹; -0.26%) and improved relative maximal FH (8.3 to 10 N·kg⁻¹; 15%) and power (18 to 20 W·kg⁻¹; 13%). The athlete also increased FH in his "weak" leg (2.7 to 3.1 N·kg⁻¹; 15%) thereby decreasing his original FH asymmetry (52 to 45%; 13%). Greater outcomes were found in weeks 10-12 compared to weeks 7-9. **DISCUSSION** We examined both global force production and individual contribution from each leg during a maximal sprint and found encouraging alterations in performance and injury risk variables as a result of targeted hip extension exercises. These changes are very likely the result of the exercise prescription to increase FH (via hip extension) in the "weak" leg, thus elevating global FH and subsequently performance while simultaneously reducing the FH asymmetry between the legs (Morin et al., 2015). These pilot findings may have strong implications for individualised programming to both increase sprint performance and decrease injury risk. **REFERENCES** Brown SR, Cross MR. (2015). COMPARISON OF MUSCLE ACTIVITY DURING STUMP STRAPS BENCH PRESS AND CONVENTIONAL BENCH PRESS ON SELECTED UPPER BODY MUSCLES.

GAVANDA, S., GEISLER, S., ILKENHANS, A.J., STRACK, N.

IST Hochschule

Background: The "stump straps bench press" (STBP) is a variation of the conventional bench press (CBP) where some or the total amount of weight is attached to a barbell with flexible straps, so the weight hangs freely in the air. This study investigated the influence of STBP on muscle activity of chosen upper body muscles. **Objective:** The aim of this study was to compare muscle activity of the triceps, pectoralis major and deltoideus anterior during STBP and CBP on a flat bench. **Hypothesis:** Performing STBP requires greater muscle activity than CBP due to the free-hanging weights, which need to be stabilized throughout the entire range of motion. **Methods:** All of the participants (12 male resistance trained sport students) completed a 1 RM test prior to the study. With at least 3 day between the pretest and the intervention all subjects performed the bench press exercise with 4 sets of 10 repetitions (60% 1 RM) in a predefined cadence (2 s eccentric, 1 s isometric hold on the chest and a 1 s concentric). Two sets of STBP and two sets of CBP in randomized order with double acromial grip width. Group A (n=6) started with two sets of CBP followed by two sets of STBP with 3 minutes rest between sets. Group B (n=6) performed the same schedule but in reverse order. Repetitions of the first set were compared with repetitions of the third as well as the second set with the fourth. **Results:** There were no significant differences in none of the evaluated muscles between STB and CBP in EMG muscle activity. **Discussion:** One reason for these non-significant results could be the chosen percentage of the 1 RM, which might be too low to elicit alterations in muscle activity. Furthermore there might be differences in stabilizing muscles of the shoulder (e.g. rotatorcuff) which were not examined in this study. Additional research with higher subject populations are recommended.

POSTACTIVATION POTENTIATION: EFFECTS OF VARIOUS CONDITIONING CONTRACTIONS ON BENCH PRESS POWER PERFORMANCE

PARSTORFER, M., ULRICH, G.

University of Heidelberg

University of Heidelberg, Institute of Sport and Sport Science Introduction Intense muscular contractions can enhance subsequent force generation thus leading to an enhanced muscular power performance. This phenomenon is called Postactivation Potentiation (PAP; Tillin & Bishop, 2009). The purpose of this study was to evaluate PAP-effects produced by three different conditioning contraction (CC) stimuli on upper body power performance. Methods Sixteen healthy resistance-trained male sport students (age, 23.1±3.2y; height, 183±9cm; body mass, 83±11kg; strength training/week, 3.8±1.8h; bench press one-repetition maximum [1RM], 97.6±16.6kg) volunteered to participate in the study. The 3 experimental trials composed either a concentric-eccentric (CON-ECC: 1 set of 3 repetitions at 87% of 1RM on a bench press), an eccentric only (ECC: 1 set of 3 repetitions at 120% of 1RM on a bench press) or a plyometric (PLY: 1 set of 10 plyometric push-ups) CC stimulus. The experimental sessions were performed on different days separated by a minimum of 48h, and determined randomly. Maximal muscular performance, as determined by a ballistic bench press throw at 30% 1RM, was measured before (baseline) as well as 1, 4, 8, 12 and 16 minutes after each CC stimulus via Myotest (Myotest SA Switzerland). Results Compared with baseline (CON-ECC, 914.5±138.0W; ECC, 925.8±144.3W; PLY, 920.1±145.1W), bench press power performance was significantly enhanced in CON-ECC (943.1±139.7W; P<0.05) after 8 minutes of recovery. However, no significant changes were obtained in ECC (912.0±155.2W) and PLY (947.6±149.2W). The results obtained from the comparisons between baseline power performance and the individual best power performance for each subject after each CC stimulus showed significant increases in CON-ECC (P<0.017; +5.7%) and PLY (P<0.017; +4.9%) CC

stimuli. There was no significant difference in ECC ($P>0.017$; +1.8%). Discussion Our results indicate that after 8 minutes of recovery, CON-ECC CCs generated increases in bench press power performance. However, considering an individual recovery period, PLY CCs lead to an enhanced power performance in the bench press exercise as well. Due to the practical application prior to a competition, PLY CCs could be an interesting part of warm-up strategies aiming to improve upper-body power performance. EFFECT OF A CORE TRAINING PROGRAM ON MALE HANDBALL PLAYERS' THROWING VELOCITY

MANCHADO, C., GARCÍA-RUIZ, J., TORTOSA-MARTINEZ, J., CORTELL-TORMO, J.M.

UNIVERSIDAD DE ALICANTE

In handball, throwing velocity is considered to be one of the essential factors in achieving the ultimate aim of scoring a goal. The objective of the present study was to analyze the effect of a core training program on throwing velocity in 30 handball players (age 18.7 ± 3.4 years, height 179.3 ± 7.0 cm, body mass 78.9 ± 7.7 kg), 16 of whom were in the junior category and 14 of whom were in the senior category. The 30 players were randomly divided into two groups, the control group ($n=15$) and the experimental group ($n=15$). For a period of ten weeks, both groups attended their regular handball training sessions (four per week), but in addition, the experimental group participated in a program specifically aimed at progressively strengthening the lumbo-pelvic region and consisting of seven exercises performed after the general warm-up in each regular session. Pre- and post-tests were carried out to analyze each player's throwing velocity from different throwing positions and thus assess the effects of this specific training program. Statistically significant differences ($p \leq 0.05$) in throwing velocity were observed between the experimental group and the control group. The results seem to indicate that an increase in the strength and stability of the lumbo-pelvic region can contribute to an improvement in the kinetic chain of the specific movement of throwing in handball, increasing throwing velocity

INFLUENCE OF NON-WEIGHT-BEARING HIP POSITION ON KNEE VALGUS IN DYNAMIC TRENDLENBURG TEST

KAGAYA, Y.

Showa University

Introduction To identify athletes at a higher risk of non-contact anterior cruciate ligament (ACL) injury, we developed a two-dimensional (2D) screening test focused on hip abductor and rearfoot function (Kagaya et al., 2015). However, influence of non-weight-bearing hip position on knee valgus in dynamic trendelenburg test (DTT) evaluating hip abductor function remains ambiguous. The purpose of this study was to determine the useful instruction for the subjects when DTT was evaluated. Methods Sixty-nine female basketball players (137 limbs) agreed to participate in this study. Their age was 15.8 ± 1.6 years, height and weight were 157.8 ± 5.5 cm and 48.7 ± 6.1 kg, respectively. Subjects performed two kinds of single-legged squatting at different non-weight-bearing hip position. The first position was decided as the contralateral hip straight, and the second position was decided as the contralateral hip bent to about 60° . This procedure was recorded simultaneously using a 2D video camera in the front and the back on the subjects. Knee-in distance (KID) and Hip-out distance (HOD) were measured using 2-dimensional video images filmed at 30 Hz. KID was measured as distance from hallux to the point where the line connecting the center of the patella and the anterior superior iliac spine (ASIS) intersects the floor. HOD measured as the distance from hallux to the projection of ASIS on the floor. Hip abductor function and rearfoot dynamic alignment were evaluated by a dynamic Trendelenburg test (DTT) and a dynamic heel-floor test (HFT), respectively. Results The prevalence of DTT-positive demonstrated 33.6% (46 limbs) in non-weight-bearing hip straight, and 0% in non-weight-bearing hip bent. With regards to DTT-positive subjects (46 limbs) in non-weight-bearing hip straight, the hip straight task demonstrated greater KID (12.8 ± 3.1 cm, 9.2 ± 3.9 cm) and HOD (14.1 ± 1.7 cm, 13.0 ± 2.0 cm) than the hip bent position ($p<0.001$). Additionally, the hip straight task demonstrated higher prevalence of HFT-positive (54.4%, 30.4%) than the hip bent position ($p<0.01$). Discussion For the single-legged squatting, we instruct for the subjects to clasp their hands behind their backs and balanced on one leg without the contralateral hip bent. As the results of this study, the difference of non-weight-bearing hip position during single-legged squatting affected the prevalence of DTT-positive. Hodges et al. (1997) reported that the abdominal muscles, particularly transversus abdominis muscle, recorded the electromyographic activity prior to the onset of rectus femoris muscle in rapid flexion of the hip. Thus, it is thought that activities of abdominal muscles are facilitated in non-weight-bearing hip bent position, compared to in non-weight-bearing hip straight position, and which influences contractions of hip abductor muscles in weight-bearing hip. As a result of this experiment, an importance of integrating the conditions was recognized, and henceforth it is needed to establish an evaluation involving core muscle function.
